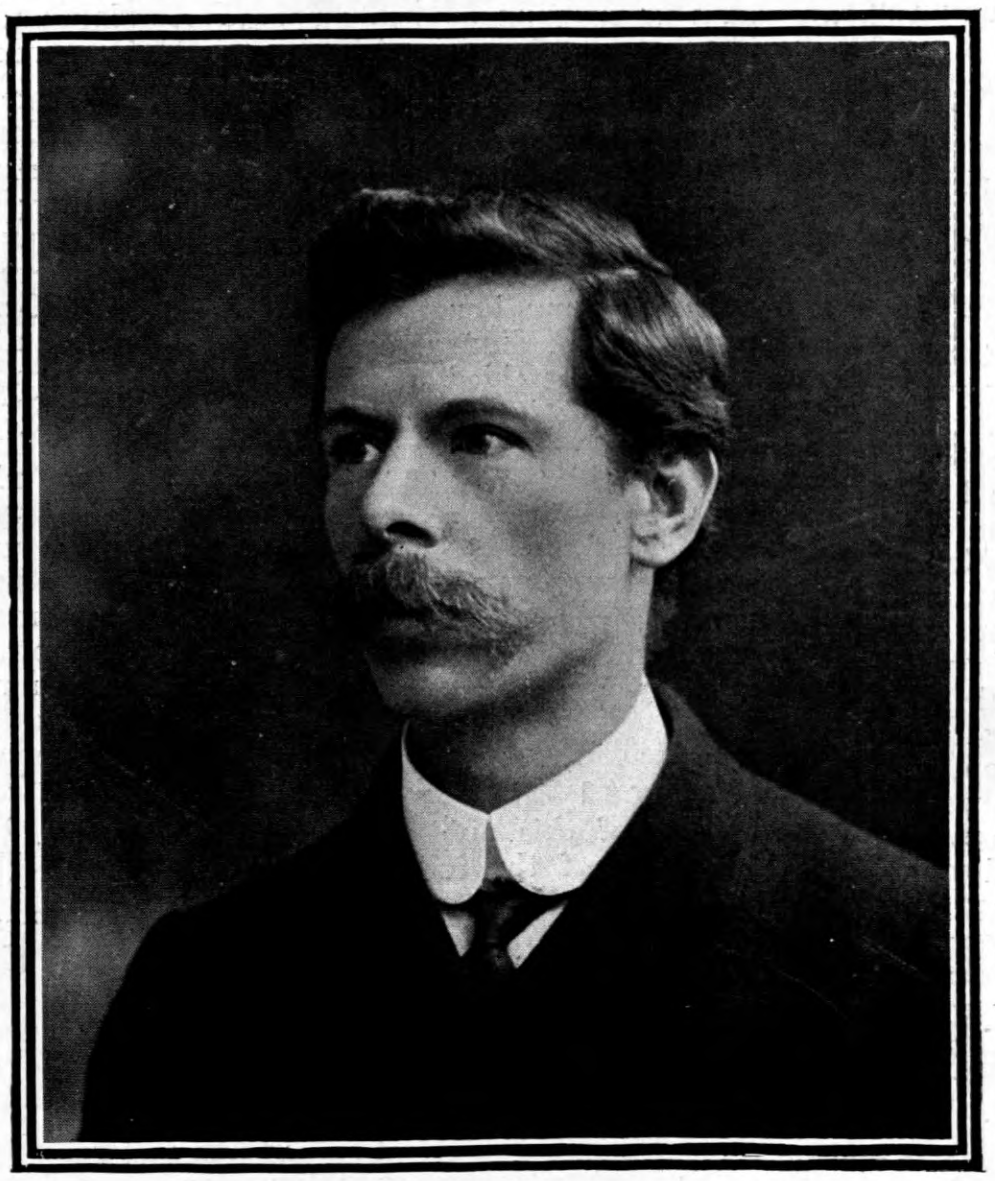
THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Progress and Prospects of Rose Growing.

So great an advance has been made by many of the more important classes of plants utilised in beautifying the flower garden that it would not be an easy task to determine with the proper degree of exactitude those groups in which the greatest progress has been made. Nor is it necessary to institute such comparisons as would enable us to determine the point. For our present purpose it will suffice to say that a host of occupants of the flower garden have been immensely improved, and their popularity greatly enhanced as the result of the well-devised efforts of those who give their attention to the interesting and highly-important work of plant improvement in relation to the ornamental aspects of the garden. At no period in the history of gardening in this country have the raisers of plants adapted for garden decoration been more active than during the past few years, and certainly at no time have they been so successful in the enrichment of gardens with plants that are at once quite hardy and well able to contribute liberally to the interest and attractions of the flower garden. Chief among the several groups in which marked advances have been made are the roses, and the changes and improvements in these have been such as to greatly enhance their popularity, and to well-nigh revolutionise the methods of procedure that find favour with cultivators. Within quite recent times quite new types, such as the wichuraianas, have been created, and some of those already in existence, notably the hybrid teas, have been so immensely improved as to have had their value for garden decoration increased by at least a hundredfold. The progress made in the development and the cultivation of the climbing and rambling roses has been so marked that the aspect of gardens in which the distinctive characteristics of these two sections are fully appreciated is completely changed during a considerable part of the summer season. Not so very many years ago the cultivation of climbing roses, away from walls, was usually limited to a few pillars formed with such strong growers as Gloire de Dijon and William Allen Richardson; the climbing forms of certain hybrid perpetuals and hybrid teas, and some of the ramblers, such as Aimee Vibert Scandens, and Dundee Rambler, that were introduced to cultivation in the first half of the last century. Now we have in the majority of gardens arches, pergolas, pillars, and trellises, over which the finest of



EDWARD J. RUSSELL, D.Sc.
Director of the Rothamsted Experiment Station.

the multifloras and wichuraianas that have been introduced within the past few years, run riot and produce the most delightful effects in the season of roses. The progress with rambling roses has been so great as to place those who love roses under a deep debt of gratitude to those by whom such splendid results have been obtained, but much yet remains to be accomplished among the climbers. There is for example a need for more roses of the type of Gloire de Dijon, and the raiser who succeeds in introducing tea-scented varieties possessing the vigour and freedom of flowering of this famous old rose, and affording a considerable range of colour, would render a good service to a considerable number of rosarians. Their introduction would certainly render it more easy to clothe the walls of dwelling houses with roses in a really satisfactory manner than is at present possible. Not less remarkable has been the progress among the dwarf-growing varieties, notably the hybrid teas and the dwarf polyanthas. Within a comparatively short period an immense number of hybrid teas have been added to the list of varieties available for cultivation; and from these it is possible to make a comprehensive selection of much merit for bedding and massing. The attributes of a good bedding rose are a rather dwarf and free-branching habit, profuse and continuous in flower production, and blooms pleasing in colour, borne on erect stems above the foliage. Roses possessing these attributes are numerous, and as their flowers afford a great diversity of colour there should be no great difficulty in making a selection adapted to the requirements of both large and small gardens. The progress that has been made in the development of new and effective shades of colour has not been less remarkable than the improvements that have been effected in the growth and flower production of the plants. The newer introductions have included a goodly number of crimson hybrid teas, a colour in which the section was for some time deficient, several taking high rank among the exhibition roses, and numerous varieties bearing blooms in which orange, yellow, and buff predominate. These latter mark a decided advance, and are of much value for their distinct and attractive hues, and for the aid they are so well able to render in any endeavour that may be made to carry out new and beautiful colour schemes in the rose garden. The colour of a few of these roses is greatly modified by strong sunlight, and those who contemplate the formation of an elaborate colour scheme and are particular as to the exact shades, should become acquainted with these roses as they may be seen growing in the open during the summer, previous to the season of planting, and make their selection accordingly. In turning from the past to the future, we find a prospect so full of promise as to justify a spirit of hopefulness in relation to roses. We may anticipate with the utmost confidence that the raisers will in

the near future place at the disposal of rosarians more rich crimson, brilliant red, and yellow roses; white roses in which neatness of growth, freedom, and continuity of flowering and finely-formed flowers are happily combined; and, in addition new and effective combinations of colour in the roses in which yellow or orange predominates. There is also justification for the hope that in course of time considerable improvements may be seen in the several classes of climbing and rambling roses, more especially in the direction of developing a perpetual habit of flower production. With the great wealth of material the roses afford at the present time for beautifying the garden, there is no justification for impatience in anticipating new forms and colours, and, judging from the enormous numbers of roses that are being planted this season, lovers of the flowers are taking full advantage of the varieties, new and old, that are at their command.

Dr. E. J. Russell, whose portrait we have the pleasure of giving herewith, occupied for some years the important position of the "Goldsmiths' Assistant for Soil Investigation" at the Rothamsted Experiment Station, and in the fulfilment of the duties associated therewith he gave unquestionable proofs of his commanding abilities, and rendered service of immense value to those engaged in agricultural and horticultural pursuits. Entering on the investigation of the soil, with special reference to the conditions that are favourable or otherwise to its fertility, fully equipped for the work, and possessing originality of thought in a marked degree, Dr. Russell did not adhere wholly to traditional methods. On the contrary, he proceeded along new lines of research, and thereby succeeded in contributing materially to the knowledge of the biological aspects of the soil, and assisting cultivators to deal more effectively with the problems that are constantly requiring solution. Having regard to the value of the investigations that were carried out, it is not surprising that when Mr. A. D. Hall retired a few months since from the position he occupied as the chief of the station, in order to devote his whole time to the work of the Development Commission, the trustees should at once have recognised the special fitness of Dr. Russell for filling the vacancy, and have appointed him Director. The investigations with which Dr. Russell is best known are those carried out with a view to ascertain the extent to which the micro-organisms in the soil can be controlled with advantage to the plants. It has long been known that soils undergo a change under intensive culture in glasshouses, and gradually become unfitted for the continued growth of a crop; and the deterioration of soil in cucumber houses devoted to the production of crops for markets proceeds in some instances so rapidly that it has to be annually renewed to ensure satisfactory results. The investigations showed that the deterioration was due in part to the decrease in the bacteriological activity in the soil, and in part to the increase in the organisms injurious to plant life. Also that, by partial sterilisation of the soil by heat, or treatment with carbon disulphide or toluene, the injurious organisms can be effectually kept under control. One has to be acquainted with the difficulties experienced by cultivators for market to fully appreciate the importance of the results obtained, but it will be readily seen that they will prove of great value. This is but a small part of the work that has been accomplished by Dr. Russell since he has been at Rothamsted, but it is quite sufficient to justify the anticipation that under his direction the traditions of this important centre of research will be fully maintained, if they are not, as we anticipate, greatly enhanced.

Our Almanack.—With this issue we have the pleasure of presenting our readers with an almanack for the current year which is remarkable as a splendid example of colour-printing, and will be found of much value for the information it contains relating to the exhibitions and meetings that will be held during the current year. The two roses—Mrs. Alfred Tate and Antoine Rivoire—of which portraits are given have taken a high position among varieties suitable for beds and massing in the flower garden, and fully merit the prominence thus given. No charge is made for the almanack, and subscribers should see that it is delivered by their newsagents with each copy.

Sir Frank Crisp, Bart.—We are pleased to record the fact that this distinguished horticulturist and eminent lawyer has had a baronetcy of the United Kingdom conferred upon him by the King. Sir Frank Crisp, whose surpassingly beautiful gardens, with their wonderful rockery, at Henley are well known, is the president of the Horticultural Club, has been treasurer and vice-president of the Linnean Society during the past quarter of a century, and hon. secretary of the Royal Microscopical Society for eleven years.

A Pleasant Social Function at Manchester. — A few evenings since Messrs. Dickson and Robinson, of Cathedral Street, Manchester, in accordance with their annual custom, entertained their employees at dinner, and the large company that assembled at the Victoria Hotel was of much interest, as evidence of the kindly feeling that exists between the firm and its large staff. This was further evidenced by the large proportion of the members of the latter who have been in the service of the firm twenty or more years, some having a record of service extending over forty years. Mr. Robinson presided, and the after-dinner proceedings included a few speeches, and an excellent musical programme.

"Botanical Magazine." — The current issue of this publication contains coloured plates of the following new or otherwise interesting plants: Senecio stenocephalus, an attractive species, native of Japan and of Northern China, and bearing long racemes of rich yellow flowers; the leaves are orbicular, and of large size. Rosa sertata, a beautiful Chinese species, somewhat closely allied to R. Willmottæ, with finely-divided leaves, and bearing single flowers about two inches in diameter, and of a rich pink hue. Clerodendron Bakeri, a distinct species, and a native of West Tropical Africa, where it has been collected, both in the region of the Lower Congo and in Sierra Leone; the flowers are white, and produced in axillary cymes, and present an attractive appearance. According to Mr. Scott Elliott, this species grows near rivers in Sierra Leone, and forms a handsome fragrant shrub about four feet high. Amorphophallus corrugatus, an interesting aroid, discovered by Dr. A. F. G. Kerr, in the evergreen forest on the Doi Sootep Mountain in the district of Chienmai, Siam; the spathe is greenish, suffused with rose at the margin, and marked with yellow-green spots on the outer side. The spathes are not wanting in attractiveness, but the species has but little value horticulturally. Aster Purdomi, a pretty little species, introduced from the Province of Shensi, North China, and resembling in habit the well-known A. alpinus, but is perfectly distinct from that species; it is quite hardy, has a tufted habit of growth, and bears with considerable freedom rose-coloured flowers about two inches in diameter, and enlivened by a golden disk. It should prove a useful addition to the rock garden.

Sir James Key Caird, who has had a baronetcy conferred upon him, is a jute manufacturer of Dundee, and for many years has taken a keen interest in the various movements that have had for their object the welfare of the inhabitants of the city, and has contributed freely of his wealth in the promotion of scientific work. He made a gift of £10,000 on the occasion of the visit of the British Association to Dundee in September last, and he has endowed a tuberculosis and cancer hospital for the city. The other day he gave £15,000 as a New Year's gift to provide a public park for Dundee, and a portion of the Linlathen estate, east of the city, has been purchased for the purpose.

Horticultural Club. — The first house dinner of the Horticultural Club for the current year will take place on Tuesday next, the 7th inst. Following the dinner a lecture, entitled "My Travels in Bulgaria," will be given by Mr. Herbert Cowley, and will be illustrated by lantern slides, prepared from original photographs.

The Perpetual-flowering Carnation Society has introduced an important change in the interests of gardeners. In the past 5s. per annum was the minimum subscription. It is now decided to enrol head gardeners who live upwards of 200 miles from London as associate members, at 2s. 6d. per annum, and this concession is extended to foremen and journeymen gardeners, irrespective of the 200 miles limit. Associate members will enjoy most of the privileges of full members. They may attend any of the society's meetings, but cannot vote, and are not eligible for office. They will be entitled to one non-transferable ticket for each show, and a copy of the "Carnation Year Book," which will be sent, post free, to all associates. The society has resolved upon the above concession in favour of gardeners because a desire had been expressed by some to become identified with the society, but they considered the 5s. subscription too much for those who could not attend all the shows. It is hoped that many will avail themselves of the opportunity now presented. Mr. L. J. Cook still retains the office of hon. treasurer, but all subscriptions should be paid to the hon. secretary, Mr. T. A. Weston, Floradale, Orpington.

Francis Darwin, Esq., D.Sc., F.R.H., the third son of Charles Darwin, whose assistant he became after studying medicine at St. George's Hospital, has had the honour of knighthood conferred upon him. He has attained high distinction as a botanist, and was president of the British Association in 1908.

Window Gardening at Preston.—With a view to render the streets of Preston less sombre than they usually are, the Preston and Fulwood Horticulture Society have decided to carry out the scheme prepared by Mr. W. N. Wood for encouraging householders to cultivate window plants, and to beautify their residences with window boxes. To ensure the success of the scheme, it has been decided to form a committee in each ward of not fewer than twelve members, each ward committee to elect its own chairman and secretary, three from each ward to be elected on the General Committee. The duties of the Ward Committee will be to arrange at least one free public lecture dealing with the

care of window boxes, etc., and to invite entries for window plants and window boxes, for which prizes will be offered. Window plant exhibits will be open to all from 13 to 18 years of age, and another class is to be arranged for those over 18 years of age. The competitions in the window box classes will include householders where the rent does not exceed 6s. a week, householders where it does not exceed 10s., an open exhibition with the exception of householders in Winckley Square, and another open to all householders in Winckley Square. Details were left to a strong committee, but the whole scheme will be "fathered" by the society, though it is hoped to induce the townspeople generally to ensure there shall be no financial loss. It is estimated that the cost of carrying out the scheme will not exceed £60, and there should be no difficulty in raising that amount in a town such as that of Preston.

Marram Grass for Paper-making.—Among other plants suggested as suitable for the paper-maker which have recently been examined in this connection, says the "Kew Bulletin," is the common Marram Grass of our coasts, Ammophila arenaria, Link. This grass, as is well known, is grown on the sand hills around our shores and acts as a very valuable sand-binder. It now appears that it possesses quite useful qualities as a source of material for paper-making. Messrs. Clayton Beadle and Stevens have kindly examined a consignment of Marram Grass sent through Kew from the Norfolk sand hills. They report that the grass was boiled under pressure, without passing through crushing rollers, and then bleached. The figures for the yield of unbleached and bleached fibres, expressed on the original green weight of stem as received and on the dry weight, are as follows: Unbleached green stem, 17.2 per cent.; unbleached dry stem, 31.4 per cent.; bleached green stem, 13.1 per cent.; bleached dry stem, 25.0 per cent. The average length of unbeaten fibres contained in the pulp taken on an average of ten measurements was found to be 0.65 mm. Marram Grass is found to produce a soft pulp with a short tear which more nearly resembles in general feel and external appearance the pulp produced from Esparto or chemical aspen wood pulp. The primary function of Marram Grass is, of course, as a sand-binder, but it is possible that should it be deemed of sufficient importance as a paper-making material its cultivation could be extended over considerable tracts of sandy country bordering the coast in various parts of the British Isles.

Presentation of Plants to the Glasgow Parks.—The already splendid collection of plants in the winter gardens of the leading public parks of the City of Glasgow, has received a considerable addition through a generous gift. This arose through the offer, by the trustees of the late Mr. James Coats, jun., of Ferguslie, Paisley, of the whole or any portion of the contents of the range of houses, seven in number, at Ferguslie. The convener of the Parks Committee and Mr. James Whitton, the superintendent of parks, visited Ferguslie, and the generous offer of the trustees was accepted, with the result that the parks receive a large acquisition of plants of varied kinds, including some good specimen palms and other subjects of decorative value. Mr. Coats had a fine collection, and it is seldom that a community have such an opportunity of acquiring so many useful plants.

We wish the movement every success, and hope the society will receive the support of the townsfolk in this new departure.

THE BEST TWELVE WINTER-FLOWERING ORCHIDS FOR GENERAL PURPOSES.

In selecting a dozen of the best winter flowering orchids one might be inclined to choose the newer introductions, but, as this is not within the scope of the editor's request, I have selected kinds which are procurable at a reasonable outlay, and in general cultivation.

The following kinds possess much beauty, and are suitable for cultivation under the conditions that usually obtain in gardens:

Where there is a stove or warm house available, Cattleya labiata makes a good display through the months of November and December. Since its reintroduction it has become readily obtainable. Importations are arriving annually, and it is desirable to procure the plants when newly imported, as there is always a greater interest

CATTLEYA FABIA.

A richly-coloured hybrid raised from a cross between C. Dowiana and C. labiata. The specimen illustrated formed part of the fine collection of cattleyas exhibited by Lieut.-Col. Sir George Holford (grower, Mr. H. G. Alexander) at the R.H.S. Orchid Show in November last.

attached to those which have not previously flowered. Moreover, the plants bloom more freely when first imported. Cattleya Fabia is a beautiful hybrid derived from the inter-crossing of C. labiata and C. aurea, and has now become freely distributed. It is exceedingly variable, and I consider it the best of the winter-flowering cattleyas. It is good in constitution and flowers freely.

These are best grown in pots, filled to two-thirds their depth with clean broken crocks, using a compost of fibrous peat, some broken oak or beech leaves, and chopped sphagnum moss, with sufficient sand, etc., to render the compost open and porous. The temperature should not be less than 65 deg. during winter.

Calanthes are of much value for the production of flowers in winter, and may be successfully cultivated under stove treatment. It is a difficult matter to choose

between C. Bryan, C. William Murray, and C. Veitchi. I am, of course, leaving unmentioned the newer kinds. My vote must go to C. Veitchi, as its rosy-pink flowers are most attractive on well-grown plants. This hybrid requires annual repotting, which is best done in the spring at the time when the new roots make their appearance at the base of the newly-developing growth. Flowering in December and January, the plants are exceedingly serviceable.

Dendrobium Phalænopsis is quite unsurpassed in usefulness where there are suitable conditions under which to cultivate the plants. Unfortunately they are affected by fog and impure atmosphere, and are unsuitable for the neighbourhood of large towns and smoky districts. It blooms from October to February, and the flowers last a long time in good condition when used for decorative purposes in a cut state. The plants are best grown in baskets, or well-drained pans, with a compost of peat or Osmunda fibre and chopped sphagnum moss.

With an intermediate division, in which it is possible to grow many attractive kinds —and noteworthy among them are the zygopetalums—a temperature of 55 to 60 deg. is maintained. Zygopetalum Mackayi, in large plants, are most effective, and, flowering in the depth of winter, they are exceedingly serviceable. Use well-drained pots, with a compost of two parts fibrous loam and one of peat and chopped sphagnum, intermixed with sufficient sand, etc., to render the compost porous. The plant is evergreen, and should not be subjected to rigorous resting conditions. Cœlogyne cristata, of which I should preferably select C. c. alba, flowers at the end of January and during February, and is exceedingly useful when flowers are usually scarce. Potting is best done immediately after flowering, using fibrous loam, peat, and chopped sphagnum moss in about equal proportions. Liberal root moisture is required throughout the growing season, and just sufficient water is necessary when dormant to keep the pseudo-bulbs in a normal plump state. Vanda cærulea is distinct and of great beauty, but requires a pure atmosphere, and unfavourable outside conditions render the plants useless, as with but little fog the buds drop, and dull surroundings cause the flowers to come white instead of the delightful shade of blue so characteristic of the species.

From the cypripediums I am compelled to select four to produce flowers in November, December, January, and February. Preferably I will take C. insigne (for choice C. i. Sanderiæ), C. Leeanum Clinkerberryanum, C. Hera Adrastes, and C. Calypso. These are best grown in well-drained pots in a compost of fibrous loam and peat, with chopped sphagnum and sufficient sand, etc., to render the compost porous. Potting is best done immediately the plants pass out of flower, making the compost moderately firm about the roots. Epidendrum vitellinum majus is of special value for the purpose in question. It commences to bloom late in the autumn, and its brilliant scarlet flowers last in perfection on the plant for three or four months, or for weeks after they are cut. Grown under the same conditions as those found suitable for the odontoglossums, it gives every satisfaction. The potting compost should be two parts peat to one of sphagnum moss and chopped oak leaves. This plant does not need repotting frequently; and, as long as there is ample pot room, and the compost is in good condition, the roots should not be disturbed. The plants require liberal root moisture at all seasons of the year.

H. J. Chapman.

PAMPAS GRASS.

The Pampas Grass (Gynerium argenteum) is one of the noblest and most effective of all grasses grown in our gardens. But it is a fact that in some gardens the plants are very much neglected, and those that are so neglected present a very untidy appearance.

In the counties south of the Midlands the pampas grass does not require much protection from frosts, but in the Midland and Northern counties it is well to afford them some in very frosty weather. Mats are the best for the purpose.

I have, however, seen old specimens choked, as it were, through the accumulation of portions of the scales of the thickest parts of the stems falling into the heart of the plant and being allowed to remain there for several years. These dried outer scales do not decay readily, and so, in about three years' time, there will be sufficient accumulation to cripple free growth. Having had in my charge some good specimens from time to time, I always made it a rule to clean out the dried grass twice every year—in summer and again in spring.

Small plants may be well grown in soil which has only been deeply dug, but the best specimens are those that have been planted in deeply-trenched ground.

The Most Suitable Soil and Position.

If the ordinary soil is rather poor and shallow some good turf, in which the grass has died, after being stacked about ten weeks, must be added for the benefit of each plant. A rich, deep loam is an ideal one for the plants, and in such the cultivator can keep them in a fine vigorous condition for many years.

A gently sloping plot of ground facing the south or south-west is a good one for the pampas grass. In the southern counties protection from north and east winds is not absolutely necessary where the grass is grown on such sloping ground, but in the north it is advisable to have a belt of trees and shrubs on the north and east sides, but not necessarily close to them.

One of the finest plantations of the pampas grass I ever saw was made at Hinton Admiral, the Hampshire seat of Sir George Meyrick, Bart., some years ago, on a south slope, covering a considerable space. The plants did remarkably well, and looked charming in contrast with the dark conifers and other trees which formed their background or framework. At Highcliff Castle, Hampshire, owned by General Stuart-Wortley, there is a charming group composed of pampas grass, Prunus Pissardi, and kniphofias. From August to October this bed looks extremely well. Here, again, there is a framework of large trees and luxuriant shrubs, with the grey walls of the castle in the background. Of course, the bed is a large one, and there is not any overcrowding. The yearly work essential to the keeping in order of such a large border is really not a big item. Plant the pampas grass in April.

Geo. Garner.

Single-flowered Chrysanthemums.—Great improvements have taken place in the single-flowered section of chrysanthemums within recent years, the tendency being to favour large or moderately large flowers. A notable feature of some at least of the newer kinds is the presence of an anemone-like centre, instead of the usual disc, indeed, the most pronounced in this respect suggest that only another turn of the wheel is required to bring us around again to the old section of large-flowered anemones. —W. T.

THE DIPLADENIAS.

Although there are no more beautiful stove climbers than several of the species of dipladenia, it is a rare occurrence to find them grown in private gardens. Twenty years ago the majority of nurserymen grew several species with varying degrees of success, but since that time the demand has been so slight that only a few growers who specialise in stove plants find it worth their while to stock them. Few of the visitors to the London exhibitions know what a dipladenia is, and it is only at the more important provincial flower shows, such as that held at Shrewsbury, that these beautiful plants are exhibited.

I do not know any plant which is more susceptible to injury from mealy bug, or any plant which the pest seems to be so fond of, and once a specimen becomes infested the foliage very quickly shows signs of distress. The leaves have so many hiding-places that the general methods of combating the mealy bug, by sponging with insecticide or by applying it in stronger doses with a small brush, are very ineffectual. The best method is that of spraying the plants with petroleum emulsion, and, as prevention is better than cure, it is a good plan to do this work at regular fortnightly intervals from the time growth commences until the first flowers have expanded. In this respect it is a curious fact that while periodic fumigation, as a means of prevention, is practised in many gardens, the spraying of plants which are easily affected by (one is tempted to write addicted to mealy bug, is not included in the routine of gardening. We usually wait until the pest has increased sufficiently to be easily apparent before we take steps to check it. Yet spraying or syringing plants with petroleum emulsion not only destroys most insects, but cleans and freshens the foliage as well. Dipladenias are splendid companion plants to the climbing species of allamanda, and are amenable to much the same treatment, except that the very firm potting, which is practised to ensure floriferousness, must not be followed with the dipladenias. From the time the plants are in full growth until the flowers open copious waterings are essential, and this requires ample drainage. The best compost is roughly-broken, fibrous peat, and turfy loam, with leaf-mould in equal quantities, with the addition of plenty of charcoal and coarse sand. Healthy plants produce numbers of flowers throughout the late summer and autumn, during which period the atmosphere of the glasshouse must be kept drier, or the flowers will be spotted. During the winter the water supply must be lessened, but not entirely withheld, for while dipladenias require a thorough season of rest, they suffer somewhat from excessive dryness of the soil.

There are two dozen or so of different dipladenias described in "Nicholson's Dictionary of Gardening," and twelve are starred as being especially worthy of cultivation, but only half a dozen of these may be found named in nurserymen's catalogues. These are D. amabilis, which bears clusters of large rosy-crimson flowers; D. amœna, with rose-flushed flowers, and rich dark green leaves; D. boliviensis, the flowers of which are white, with a golden throat, and are considerably smaller, but abundantly produced; D. Brearleyana, one of the most floriferous of the larger-flowered sorts, the flowers are the biggest of all, they open pink, and when mature are of a rich crimson colour; D. hybrida, very large crimson-red flowers and light green leaves; and D. insignis, a very strong-growing kind, which bears bold rosy-purple flowers.

CLAY'S

CLAY'S FERTILIZER is the Renowned Plant Food

CLAY'S LONDON FERTILIZER

TRADE MARK

Every Genuine Tin, Bag, and Seal bears the above.

CLAY'S FERTILIZER.—A perfectly safe and useful manure containing the three chief elements of plant foods, viz., nitrogen, potash and phosphoric acid. It is a proprietary specific in general use, adaptable to all forms of soil preparation, and is applied with advantage to plants in pots, and for the production of flowers, fruits, and vegetables grown in the open. (Cassell's Dictionary of Gardening, p. 217.)

Used in the Royal Gardens, throughout the grounds of the Royal International Horticultural Exhibition, 1912, by Local and Municipal Authorities, and by Horticulturists universally.

Sold Everywhere in Tins, 6d. and **1/-**; **Branded and Sealed Bags:** 7 lbs., **2/6**; 14 lbs., **4/6**; 28 lbs., **7/6**; 56 lbs., **12/6**: 112 lbs., **20/-** Or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order (except **6d.** TINS).

CLAY'S SUCCESSFUL GARDENING. A Complete Guide to Gardening, by Eminent Writers, including Directions as to the use of CLAY'S FERTILIZER, 4th Edition (Second Reprint), 276 pages, Clear Print, Good Paper, Bound in Cloth. Burpee's Annual for 1913

"The Leading American Seed Catalog"

Is now ready for mailing. The first edition of more than four hundred thousand copies will soon be distributed. As usual it is sent unsolicited only to "Customers of Record." We shall be pleased, however, to mail a copy immediately upon application (a postal card will do) to every one who appreciates QUALITY IN SEEDS.

This SILENT SALESMAN (and we employ no "talking" salesmen to solicit orders) tells the plain truth about The Best Seeds That Can Be Grown. Besides coloured plates of Burpee-Specialities, this bright book of 180 pages shows hundreds of the choicest vegetables and most beautiful flowers, illustrated from photographs. It is almost indispensable to all who garden either for pleasure or profit.

The "HOUSE OF BURPEE" is known the world over not only as EXPERTS IN SWEET PEAS but also as SEED SPECIALISTS. No other American firm has ever introduced so many novelties of sterling value—and no other growers supply seeds annually direct to so many planters. It might be to your interest to read THE BURPEE-ANNUAL. It will cost you only one cent for a post-card to send us your address, and you are under no obligation to buy. We never annoy applicants with "follow-up" letters!

Shall we mail **you** a copy? If so, kindly **write to-day.**

NEW HARDY TREES AND SHRUBS OF 1912.

As in previous years, the new trees and shrubs from China loom largely among the novelties of the season, and, what is more, they are likely to hold a high position for some time.

As a variety of the Manuka of Australia and New Zealand (Leptospermum scoparium) was at the International Exhibition, held at Chelsea, awarded a cup as the finest novelty in the show, and was, in addition, given a first-class certificate by the Royal Horticultural Society, it certainly deserves premier mention. The Leptospermum referred to is L. scoparium Nicholli, in which the flowers, instead of being white, as in the type, are of a bright carmine-crimson, with a somewhat deeper centre. The tiny leaves, too, are tinged with purple. A second variety which received an award of merit is Boscaweni, a plant of looser habit than the type, while the flowers are in colour whitish, with a red centre. The unopened buds are bright red.

Exception may perhaps be taken to including these Leptospermums among hardy trees and shrubs, on the ground that they are tender in most parts of these islands, which is really the case; but in favoured districts, especially in the West, they succeed perfectly out of doors, and form delightful specimens.

Chinese shrubs claim one of the two other first-class certificates awarded by the R.H.S., as that honour was, on August 27, conferred upon Cotoneaster divaricata, a low, much-branched evergreen, with neat, dark green leaves, and deep scarlet berries.

The following shrubs have at different times of the season received awards of merit: Ribes laurifolium, a singular-looking species with drooping racemes of yellowish-green flowers (February 20); Corylopsis multiflora, which bears, while quite leafless, long pendulous racemes of yellowish flowers, very suggestive of the catkins of the hazel (March 5); Corylopsis Veitchiana, a good deal like the last, but more vigorous in growth (March 19); Camellia cuspidata, a dense-growing bush with comparatively narrow leaves, and single white flowers (April 2); Viburnum Davidi, a very distinct dwarf evergreen, with broadly ovate, much reticulated leaves, and dense corymbs of white flowers, which are succeeded by small blue berries (April 2); Deutzia longifolia, which bears a profusion of rather large blush, mauve-tinted blossoms (April 30); Deutzia Veitchi, whose bright rose flowers with a suffusion of purple are among the largest of all the Deutzias, and borne in great profusion (May 22); Hydrangea Sargenti is a very distinct species, with large, handsome, velvety-green leaves, the flowers borne in broad heads, being for the most part small and of a bluish tint, the large, sterile ones being limited to a scattered few around the outside of the cluster (May 22); Berberis Stapfiana, a dense-growing, deciduous species, with yellowish flowers, and a profusion of translucent red berries somewhat suggestive of red currants (October 8); Pyrus Veitchiana, a quick-growing tree, furnished with broadly ovate, finely-toothed leaves, and bearing a profusion of comparatively large, rather dull, crimson fruits (October 8); Cotoneaster bullata, of vigorous growth, probably a small tree, with curiously puckered leaves, and clusters of large, shining crimson berries (October 8); Cotoneaster salicifolia rugosa, a lax-growing bush, whose semi-pendulous shoots are furnished with bright red berries (October 8); and Cotoneaster Zabeli, a good-sized shrub with dull crimson-coloured fruits (October 8).

The New Zealand Plagianthus Lyalli also known as Gaya Lyalli, by no means a novelty, was the only other shrub to get a First Class Certificate in 1912, after an Award of Merit in 1911; while its near ally, Hoheria populnea, also a New Zealander, obtained this last-named award on November 5.

To the garden varieties of Philadelphus, raised by M. Lemoine, of Nancy, two awards were made, and though they do not represent the newest forms, they are both very meritorious flowering shrubs. The varieties are Bouquet Blanc and Voie Lactee. Other subjects that gained the same honour are Rhododendron Cornubia, a hybrid between R. Shilsoni and R. arboreum; Primus Pissardi Moseri flore plena, a double-flowered plum, of considerable value for forcing purposes; Abies Douglasi Fletcheriana, a dwarf form of the Douglas fir, and Clematis Lady Betty Balfour, a large flower of a deep violet-purple, with a crimson bar down the centre of each petal.

COTONEASTER BULLATA.

A Chinese species remarkable for its elegant habit and rich crimson fruits. Introduced by Messrs. J. Veitch and Sons.

Of the different subjects enumerated above, illustrations of the following have appeared in the GARDENERS' MAGAZINE, thus giving readers a far better idea of their general appearance than a long description: Corylopsis multiflorus, March 9; Rhododendron Cornubia March 16; Viburnum Davidi, April 6; Deutzia longifolia, May 4; Hydrangea Sargenti, June 1; Philadelphus Bouquet Blanc, June 29; Clematis Lady Betty Balfour, July 13; Philadelphus Voie Lactee, July 20; Plagianthus Lyalli, July 27, and Prunus Pissardi Moseri flore plena, October 26.

A notable feature in connection with the awards made by the Royal Horticultural Society is that in 1911 no fewer than nine rhododendrons were honoured, whereas in 1912 there was only one.

Various Chinese shrubs, apart from those previously mentioned, are being distributed by Messrs. J. Veitch and Sons, all introduced by their collector, Mr. E. H. Wilson, the most promising being Berberis brevipaniculata, a free-growing, deciduous species that forms a dense bush 6ft. or so in height. The flowers are pale yellow, and the berries of a bright rosy-red colour. The rich red bark of the young shoots forms a striking winter feature. Daphne retusa, a dwarf evergreen species, whose sweet-scented white flowers with a rosy suffusion are borne in May. Deutzia Wilsoni, a vigorous grower with large pure white flowers. I was very much struck with this grand flowering shrub last spring at Coombe Wood. Ilex Veitchi, a stronger-growing growing form of the now well-known Ilex Pernyi.

Osmanthus armatus, one of the most distinct of recent evergreens, and a shrub of slow growth. The leaves are in some instances as much as six inches in length, and about one and a-half inches wide, very markedly toothed, and of a particularly harsh texture. When mature they are of a deep green tint, but the young leaves are of a bronzy green. The small, creamy-white, fragrant flowers are, as in Osmanthus illicifolius, borne in autumn. Spiræa Veitchi, a species that produces long arching shoots crowded with clusters of white blossoms. It is particularly valuable from the fact that it blooms in July.

The yellow-flowered Tree Pæony (Pæonia lutea) has been employed by the hybridist, and M. Lemoine, of Nancy, has raised a very fine form between this species and a variety of Pæonia Moutan. The progeny, which bears the name of La Lorraine, has large, double, soft sulphur-yellow flowers. At the International Exhibition a very striking Golden Poplar was shown, under the name of Populus alba Richardi, and an Award of Merit was given it. This variety of the White Poplar was obtained and shown by Mr. A. G. M. Richard, Naarden-Bussum, Amsterdam. It is remarkable for the bright golden tint of the upper surface of the leaves, the under-sides, stems, and leaf-stalks having the pronounced white tomentum common to the typical White Poplar. As it is, like nearly all the poplars, of ready propagation and quick growth, this golden form will, no doubt, ere long be generally distributed, when it should form a striking feature in the landscape, especially as, unlike some golden-leaved subjects, the colour is retained throughout the season.

Lastly, attention may be directed to the fact that Cytisus Dallimorei, which has attracted a great deal of attention within the last few years, and was given an Award of Merit at the Temple Show of 1910, is this season being distributed to the public for the first time. W. T.

CONSERVATORIES: ANCIENT AND MODERN.

The horticultural historian with ample leisure and a well-filled library—and all good historians possess both of these necessaries—would be able to speculate most agreeably, and at length, as to the date and place of the first conservatory.

The etymology of the word conservatory is self-evident; it means a place in which to conserve, or keep, anything from injury; so, from the gardener's point of view, the conservatory is the place to preserve plants which, in their present condition, are unable to withstand our climate. Our historian would probably, in his study of the evolution of the conservatory, find its foundations in the gardens of King Solomon where, some 3,500 years ago, he enclosed a large quadrangular space with high walls to conserve the great variety of plants, shrubs, and trees he had collected. This was a great step forward from the more primitive method of protecting collections of plants by enclosing them with hedges.

The Romans appear to have made structures for the forcing of vegetables. These are recorded as being fitted with removable roofs, so that abundant air and light might be admitted during the day time. The Romans were great gardeners; many of their warrior emperors during their brief periods of peace, occupied themselves in the formation of paradises, as they euphoniously termed their gardens, and one famous Roman general at least is reputed to have taken his gardener on his campaigns, so that when encamped he might have a garden around his tent. We can easily conceive such men, as soon as they had obtained a footing in Britain, having sent over to them specimens of the plants they were so fond of, and, finding that our raw winters killed them, erected buildings to protect these exotics during the more inclement weather. It will be remembered that the Romans were very skilful in the designing of flues for heating purposes. They did not heat their houses with open fires, but used flues, which they also carried around their luxurious baths. So we can quite imagine a Roman pro-consul in Britain designing a conservatory and heating it by means of flues. This building would almost certainly be rectangular in shape, the flat roof of lead or copper would be supported by pillars, and, on one side at least, the spaces between the pillars would be fitted with removable wooden shutters.

Soon after this the power of the Romans had reached its zenith, their troops were recalled and took with them their great civilising influence, with the inevitable result that any exotic plants which they left behind soon died, and the "conservatories" erected for preserving them were dismantled.

The historian would probably have to bridge over a very long period before he discovered any further signs of a conservatory in this country. Daines Barrington (born 1727; died 1800), lawyer, naturalist, and antiquary, the writer of legal works and of "The Naturalists' Calendar" (1767), records that the first hot-house in this country was built during the reign of King Charles II., and mentions a painting depicting the royal gardener presenting on bended knee forced fruits to the king. But the orangery, which was a necessary adjunct of the houses of the great, was fairly common before this date. These structures were almost entirely the creations of the architect who loves masonry, and who did not consider the well-being of the plants it was intended to house, and the orangery may well be considered the first conservatories of modern times. As they frequently were built adjoining the house their design had to conform with the architecture of the mansion. They were roofed with opaque materials, the only concession to the necessities of the plants being the glazed sashes in the front. Whilst these structures were only utilised for the wintering of specimen oranges, sweet bays, myrtles, pomegranates, etc., which were placed along the terrace walks during the remainder of the year, they served their purpose fairly well. But as the Italian style of gardening in this country waned, a more decorative form of gardening became the vogue, and the gardener was expected to keep the orangery bright and gay throughout the year. The difficulty of doing this with these heavy, sombre structures, which, as Nicol wrote, "often look more like tombs or places of worship than compartments for the reception of plants, and we may add the modern sort looks like a combination of shop-fronts," even when their roofs were glazed, was well-nigh insuperable.

The present-day conservatory, instead of being an ugly death-trap for plants, is at once a very ornamental structure and a home for its occupants. The great increase in popularity of outdoor gardening, of herbaceous borders, water gardens, etc., suggested the neglect of the conservatory. But no matter how well the hardy flower borders are managed, these, beautiful as they may be made during the season, are not all-sufficing. The season of the very best herbaceous border is limited, and although, as at Hampton Court, showy tender exotics may be planted to enhance the beauty of the hardier flowers this display cannot take the place of the conservatory. The garden owners of this country are too conservative in their tastes to be satisfied with outdoor pleasure gardening, and a suitable glasshouse where the pot plants can be displayed remains a necessity.

With the repeal of the window-tax in 1851, which had restricted the size of the glass used in glazing greenhouses, a great impetus was given to the designing of glass-houses of all kinds. The old-fashioned houses which necessarily contained a large amount of woodwork, and were consequently heavy and shady, soon gave place to the more modern style which is light and graceful in design, and admits plenty of light, so that plants removed from the growing houses do not suffer nearly so much as was formerly the case. There is naturally a great diversity in the sizes and styles of the many conservatories to be seen throughout the country. In the larger establishments, the conservatories built thirty years or so ago were often very large—at times unduly so—and much of their utility was sacrificed to outside appearance. As with the orangery the conservatory attached to the residence must be designed in conformity with the architecture of the building, but in other instances the welfare of the plants has happily been largely considered.

In those gardens where an enclosed flower garden, of more or less formal nature, has been laid out away from the mansion it sometimes includes a moderate-sized conservatory—a happy combination which may well be more frequently adopted. Not only has the style of the conservatory changed for the better, but the method of decoration has also greatly improved, and in future issues it is proposed to deal with the various methods of conservatory decoration, and give special prominence to those which have been introduced within recent times. CECIL AUBREY.

NUNEHAM PARK AND GARDENS.

Oxfordshire boasts many attractions, and not the least of these are the many beautiful and interesting gardens within its boundaries. These gardens are of diverse character, because the shire has an extreme length, from north to south, of over fifty miles, and is particularly well watered. The rivers Cherwell, Windrush, Thame, and Evenlode, with their numerous tributaries, serve it well, while the Thames forms its curiously tortuous southern boundary.

From Oxford the River Thames runs almost due south, past Iffley, and just where it turns westward on its way to Abingdon, there, on well-wooded and rising ground, stands the residence of the Rt. Hon. Lewis Harcourt, P.C., M.P. The extensive park and the whole estate of Nuneham Courtenay contain many fine trees, and noble specimens of oak, elm, Scots pine, Wellingtonia, and Abies Nordmanniana are to be seen from the long drive that leads from Culham Station up to the mansion. The latter is a large and solid building, with its more important frontage towards the river.

Immediately before the front entrance is a large and notable piece of topiary work. A hedge of box surrounds the whole, and immediately within this is a scroll-like design worked in berberis, which, in turn, forms a setting for the family crest—a peacock standing on a crown. The peacock is worked in green box and the crown in golden box.

Climbing Plants.

Few mansions are so beautifully adorned with climbing plants as is Nuneham, and still fewer are clothed with such a wonderful variety of subjects. An enumeration of half the kinds would seem so much like a mixed catalogue of hardy and greenhouse climbers that only a few of the more interesting can be mentioned. Lapagerias do fairly well, and flower regularly on a northern aspect. Azara microphylla grows freely, and in due season its flowers emit their vanilla-like fragrance. Lonicera gigantea superba covers a great space, and L. Henryi does well. Acacia dealbata is making headway on a southern exposure, while forsythias, escallonias, choisyas, and buddleias are used freely in all aspects and flower profusely; indeed, choisyas are a great feature in the borders next the house and on the north terrace. An immense wistaria faces westward, and a big Magnolia grandiflora thrives in a rather more southerly position, but each is a rare old specimen.

Akebia quinata, the yellow-flowered Piptanthus nepalensis, Edwardsia microphylla, Bridgesia spicata, and Physianthus albens all do well in the warmer places, and the lovely Solanum jasminoides rises to a great height on the west front with Passiflora Constance Elliott keeping it company and rising to the highest windows. Banksian and other roses, the white and fragrant Rhyncospermum jasminoides, and the charming Ipomæa Leari, flower every year, these latter receiving some protection at the base each winter.

Not only is the mansion itself thus finely clothed with choice and beautiful climbers, but the various terrace walls also offer congenial homes to those subjects that possess a more or less scandent habit. At Kew, at Cambridge, at Glasnevin, and at Edinburgh, full advantage has been taken of the many sheltered positions a garden offers for the cultivation of those rarer plants which generally find a place in our greenhouses if space allows. At Nuneham this idea has been put into practice extensively and with great success. The mansion itself offers unusual scope in this direction, and no pains have been spared to cultivate new and rare plants upon its walls, though at the same time the more beautiful of the older and well-known climbers find a happy home there. Further, a series of broad terraces on the westward side of the mansion give further opportunities for this

NUNEHAM PARK—THE MANSION, AS SEEN FROM THE UPPER TERRACE.

interesting phase of gardening, as the walls face either west, south, or north. Then, too, these terrace walls shelter large numbers of beds and borders, and here again choice plants are to be found in abundance.

The Terrace Gardens.

The upper terrace is rough-flagged, and between the stones all sorts of tiny plants, notably saxifragas, thymes, and sedums find a home. Climbing plants twine round the ornamental tops of the retaining walls, and roses abound on every hand. At the southern end of the terrace and in close proximity to the mansion is a series of ten large rose beds, each edged with Saxifraga oppositifolia, and surfaced with viola Maggie Mott. Each bed is filled with one variety of rose, and the kinds planted are Hugh Dickson, Corallina, Kaiserin Augusta Victoria, Grand Duc de Luxembourg, General Schablikine, Caroline Testout, Frau Karl Druschki, Mdme. Abel Chatenay, Francois Dubreuil, and Countess of Gosford. The advantages of thorough soil preparation are very evident in these beds of roses, for the bushes grow and blossom with the utmost freedom.

A "blue" border has been planted just outside this end of the terrace, and the chief occupants are anchusas, violas, lupins, asters, and anemones, with clematis on the walls.

Descending, the west terrace garden is found to be largely devoted to roses, eight large beds being here grouped. Viola Maggie Mott is again pressed into service as a carpeting plant beneath the vigorous bushes of Killarney, Pres. Carnot, Hugh Dickson, Francois Dubreuil, Beaute Inconstant, L'Ideale, Antoine Rivoire, and Caroline Testout roses, while each bed has a broad encircling band of Mrs. Sinkins pink that is attractive at all seasons of the year. Clematis Nellie Moser adorns the walls near at hand.

Lower still, a very sheltered, walled-in garden has water lilies for its central feature. This is the Nymphæa Terrace, and an illustration of it accompanies these notes. In the centre is a square pool of water, in which such nymphæas as Jas. Brydon, gloriosa, and chromatella are quite at home. At either corner is a bed of moisture-loving shrubs, the principal occupants being Rhododendron præcox, Andromeda floribunda, Kalmia latifolia, and Menziesia polifolia, with standards of the fine Hydrangea paniculata grandiflora rising well above them. The inner margins of these beds are planted with various irises, but principally the variety Victorine. Boxes of salvia Glory of Zurich adorn the steps of this terrace throughout the summer.

If the summary of the climbing plants on the mansion creates some surprise, then the list of plants growing against the walls and in the sheltered borders of the Nymphæa Garden, will prove still more surprising. Cestrum Newelli, a popular greenhouse climber, and Leonotus Leonurus, an orange-spiked warm house flowering plant, are here, though the latter has, so far, only stood out one winter. Plagianthus Lyalli does well against the wall, and so do Abutilon vitifolium and Medicago arborea, and the prett y Helichysum rosmarinifolium—the "Snow in Summer" of Tasmania. Hoheria populnea, Fabiana imbricata, Sophora tetraptera, Decumaria barbara, from the Southern United States, and also known as Forsythia scandens; Osteomeles anthyllidifolia, from the Pacific Islands; the Papaw (Asimina triloba); and the beautiful yellow-flowered Jasminum primulinum, are a few other plants not commonly found in gardens, and more rarely seen out of doors.

Around the Terraces.

Although the walls of the house and the several terrace gardens contain so much of horticultural interest, it must not be imagined that all the good things are grouped here, and that the rest of the gardens and grounds possess few attractions. The lower terraces are of recent date, and have been built and planted during the last six years; they, in themselves are ample evidence of the keen interest Mr. Lewis Harcourt and his family take in their gardens, but there is plenty of further evidence elsewhere.

A wide semi-circular slope below the lowest terrace has been made beautiful by planting it thickly with Rosa Wichuraiana, the true species; this rose is especially suitable for clothing slopes and banks, and here it is seen at its best. Just outside the Nymphæa Garden a long border is largely filled with the pretty Leptospermum scoparium, an Antipodean Myrtaceous shrub which flourishes here so well that self-sown seedlings are quite numerous. Near by a splendid specimen of the lovely Rosa sinica Anemone clothes the wall, and farther round groups of Soleil d'Or and Captain Hayward roses adorn the borders. Continuing northwards the use of rosemary, kept closely trimmed, and trained to the pillars and buttresses of the lower wall, is

VIEW ACROSS THE TERRACE ROSE GARDEN, NUNEHAM PARK.

The Carfax Monument is seen in the distance to the right. The rose in the border on the left is Madame Abel Chatenay, and that in the first bed on the right is Souv. de President Carnot.

very noticeable. A herbaceous border, well filled with good things, leads to the northern outskirts of the terrace, where one comes upon fine large masses of the golden-leaved Weigela and of rose Blanche Double de Coubert, bold plantings of Buddleia variabilis, and of splendid French lilacs in variety, of forsythias, pyrus, and prunus.

Stately yews, some of great size and age, lead towards the evergreen Sundial, which, with its hours and Latin motto, is worked in box, and set within a handsome hedge of Cistus ladaniferus.

Close by is the old parish church of Nuneham, a small and beautifully-kept structure, with fine hammered-iron doorways, and memorial tablets and medallions that keep in mind the Harcourts of bygone days. In the little churchyard, a verit-

THE NYMPHÆA GARDEN AT NUNEHAM PARK.

able rose garden, lie the remains of the Rt. Hon. Sir William Harcourt, a famous statesman and parliamentarian, who passed away in 1904. In the little church the following words are carved in his memory:

"At least, not rotting like a weed,
But having sown some generous seed,
Fruitful of further thought and deed,
In some good cause, not in mine own
I perish, wept for, honoured, known,
And, like a warrior, overthrown."

Around this spot the little village of Nuneham once stood, quite near the mansion, but the first Lord Harcourt had the village moved a mile or so away, to the side of the London Road, about the year 1710.

The Dell and Water Garden.

One of the fairest scenes at Nuneham Park is to be obtained from a point just outside the little church, looking north-west and north. Some idea of its beauty may be gained from one of the accompanying illustrations. Splendid beech, elm, and oak trees abound and form a fine setting for the rhododendrons, groups of new Chinese trees and shrubs, the pool and bog garden, and the little lake below, while away beyond the trees the Thames winds away northward to where the spires of Oxford rise in the distance.

Rhododendrons are fine, in the natural soil, and the foreground of the picture is occupied by a large group or bed of R. Pink Pearl. Near by is a large group of the handsome Buddleia variabilis Veitchi and a plantation of almonds.

Among the choicer shrubs along the slopes of The Dell are Olearia macrodonta, Fremontia californica, Nandina domestica, Viburnum macrocephala, Eucalyptus Whittinghamei from Mr. A. J. Balfour's home in the South of Scotland; the handsome E. coccifera, Colletia cruciata, and several specimens of our hardiest palm—Trachycarpus excelsa. Here, too, are examples of many of Mr. E. H. Wilson's plants, collected in China.

In the pool are water lilies, and all around in marshy ground are large groups of Primula japonica, P. unique, spiræas, and astilbes in variety, and Kæmpfer's Iris, with Lilium Henryi and L. rubellum thriving a little further from the water, with hardy cypripediums as near neighbours. Great masses of Hart's-tongue ferns are grouped around the base of an old elm tree on the slopes, and above these a breadth of the Red Orache is annually sown, and it provides a splendid bit of colouring during the summer and autumn.

Rough-flagged pathways lead down to the lower water garden, and narrower walks of flat stones lead amid the moist and boggy surroundings of this lower pool. Though only two years have passed since this part of the garden was designed and planted, the sheltered position has favoured the plants, and they have made good progress. Iris Kæmpferi has a quite large piece of bog to itself, but other moisture-loving irises are planted freely. Bamboos, phormiums, Mimulus Lewisi, trolliuses, hellebores, Primula japonica, hemerocallis, Fuchsia Riccartoni, Senecio Clivorum, and Ruscus racemosus, all do uncommonly well, and indicate the great variety of plants used in beautifying a piece of ground that was previously something of an eyesore.

A gently rising walk leads from this water garden round towards the northern end of the mansion. This was cut out of the sloping ground, consequently a retaining wall was necessary on the higher side. Mr. Munday, the head gardener, conceived the idea of making a rockery wall in this position, and carried it out by using wedge-shaped pieces of stone obtained from Abingdon. Above this wall, and under the trees, bulbous irises, narcissi, breadths of hardy cyclamen, snowdrops, and the exquisite Muscari conicum Heavenly Blue fill the ground, and in their several seasons provide charming floral pictures. On the lower side of the path roses are freely planted, with flowering shrubs and groups of Pampas grass.

The wall itself extends for about ten chains, and was built about six years ago. Popular subjects, such as aubrietias, free-growing saxifragas and sedums, Heuchera

sanguinea, Alyssum saxatile, and low-growing phloxes have been pressed into service for the adornment of this rockery wall, but time would fail to tell of the less common plants that thrive here. Succulent plants, grouped where the wall curves and provides a southern exposure, are a success, and the only added shelter they receive is afforded by a few branches of yew or box placed over them in severe wintry weather. Opuntia fragilis, O. arkansana, O. Rafinesqui, and Echinocereus (Cereus) viridiflorus are a few that are particularly happy among many species grown. Convolvulus althæoides is a fine feature, drooping from the top of the wall, and studded with pink flowers; Lithospermum prostratum does well, and there are fine groups of alpine auriculas, Campanula muralis, Stellaria Biebersteini, and Acaena Buchanani, a pretty New Zealand plant, in this interesting piece of wall gardening. The pieces of stone used are from two to four inches thick, rarely more, and many thousands of them have gone to the building of the wall.

Mason's Garden and Brown's Walk.

The original outlay of the gardens and grounds at Nuneham is ascribed to Capability Brown, and one long walk to the south of the mansion, cut through woodland, winding, and rising and falling, is known as Brown's Walk after this old master of landscape gardening. Where this path borders on the park, the Carfax can be seen; this is the fine conduit built by Otho Nicholson in 1610. It stood opposite the Carfax church at Oxford until 1787, when it was removed to Nuneham Park.

Mason's Garden is a sheltered spot, surrounded by hollies and yews, and it serves as a reminder of Mason the poet, who is also credited with some of the beautiful features of the place. A little tea-house here looks out upon a bank of Pink Pearl rhododendrons, some fine old magnolias, and, in summer time, upon oranges in tubs.

The formal rose garden, close by, is too much shut in by tall trees and big evergreen shrubs, and constant renovation is necessary to keep the roses in good order, either in the beds or borders. Unquestionably, the most beautiful feature of the rose garden is more or less accidental. A mass of green box faces northward, and it is literally smothered ten or twelve feet high with the lovely but coy Tropæolum speciosum. About four years ago tubers were obtained from Scotland and planted nine inches deep; for a while there was little sign of success, but now the plant thrives splendidly, and forms each year a beautiful screen of dainty greenery, studded with thousands of rich scarlet flowers.

Kitchen and Fruit Gardens.

The large wire-enclosed fruit cage that protects cherries and small fruits from the ravages of birds has been illustrated in these pages, and referred to on several occasions. It is interesting to notice that it also shelters a gull or two and a number of quails; these evidently do no harm to the fruits. This fruit cage and the brick-pillared pergola, with its very fine collection of ornamental vines, are two outstanding features of the kitchen and fruit gardens, but the long walk with choice rambler roses, supported on gas-barrel arches, is another feature that will improve, as the roses are newly planted. The iron piping, it should be added, is well painted.

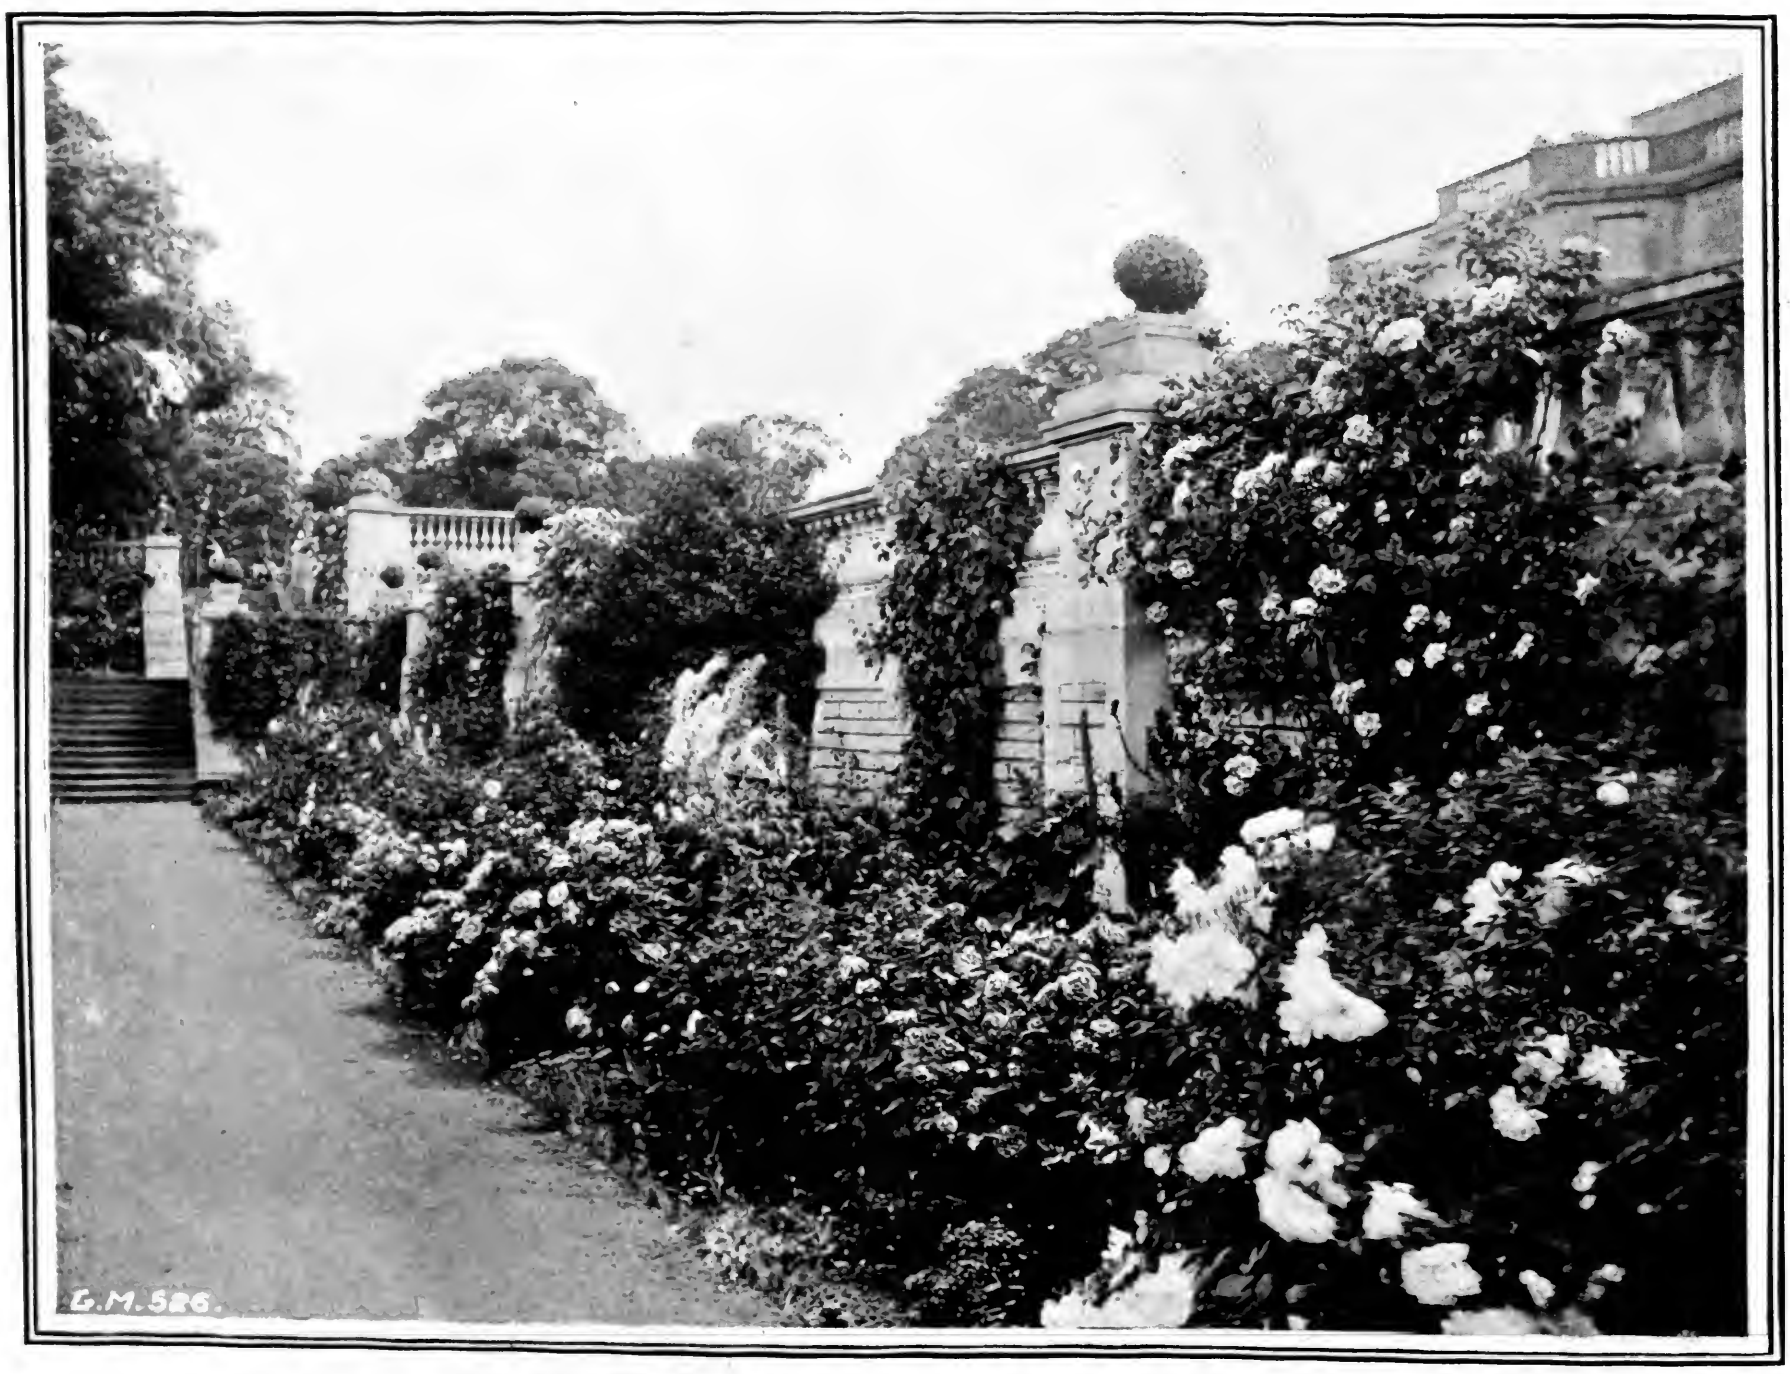
The many walls provide abundant space for peaches, nectarines, pears, and plums, while bush fruit trees are planted around the larger vegetable plots. Some of the glass houses are quite old-fashioned, but some are modern. Peaches, vines, and figs are grown well, and greenhouse plants useful for house decoration or the provision of flowers for cutting have to be grown largely. Needless to say, carnations are not omitted. Malmaison carnations are well managed, and the ever-popular perpetual varieties fill one large house.

C. H. CURTIS.

BROMELIACEOUS PLANTS.

Probably owing to the exceedingly symmetrical character of the foliage, which gives to a plant a somewhat stiff and artificial look, the different bromeliads cannot be said to be at all popular in gardens. In many of them the strap-shaped leaves are arranged in a regular vasiform manner, and are, for the most part, of a somewhat harsh texture. Some of the species, however, are very showy when in flower, among those that bloom at this season being Tillandsia Lindeni, whose blossoms are of a rich tyrian-purple colour, when represented by its best form.

Another winter-blooming kind is that which may be known as Vriesia brachystachys, but whose name is now, I believe, regarded as Tillandsia carinata. This is only about a foot in height, and has pale green leaves, overtopped by the flower spike, which, on the upper half, is furnished with two opposite rows of bright-coloured bracts, and from these the yellow flowers protrude. It remains fresh and bright for a considerable time. A bromeliad now in bloom of much merit is Æchmea fulgens, whose flowers are borne in an upright panicle. They are round, and in colour red with a blue tip. One of the most graceful of its class, and also a winter flowerer is Billbergia nutans, the flowers of which in shape resemble those of a fuchsia. The sepals are reddish and the petals yellowish-green, each with a blue margin, while they are attended by large, rose-coloured bracts.—K.



A BEAUTIFUL BORDER OF ROSES IN NUNEHAM PARK GARDENS.

EARLY VEGETABLES FROM SEEDS.—I.

In gardens where early vegetables are appreciated and others where produce is grown for sale, with the commencement of the New Year and for some time onward, a good deal of forethought, preparation, and care will be necessary to produce them.

Preparatory Work.

In many gardens the initial preparation will have already been made. Nothing is more helpful in the culture of early vegetables than a good supply of beech and oak leaves, and these before this date will have been collected and stored in the yard or leaf-pen in readiness.

The addition of a little fresh stable manure will quicken the fermentation of the leaves, which is generally sluggish if they are used alone in the open at this season of the year.

For the earliest crops of carrots and lettuce it is an advantage if, in addition to the warmth obtained by fermentation, a little fire-heat can be utilised, so long as it is well under control. It will reduce the labour and the amount of material necessary for making the beds, as well as the necessary covering in severe weather.

Where the whole source of warmth, other than that obtained by solar radiation, comes from fermenting material, in the case of beds made in the open in January, these should be at least three feet in thickness, and the sides should project nearly as much. The bed should be made with the sides levelled up to the top of the frame placed in it, and a dry site chosen. Heavy rains soaking in at the base will soon saturate and chill the material. I do not say that such quantity of fermenting material is absolutely necessary, but if the mean night temperature can be kept between 50 and 55 degrees, progress will be much faster than where lower temperatures prevail. Brick pits, with internal sunken beds, are to be preferred for the earliest crops.

In some gardens there are opportunities for growing the earliest supplies of beans and peas in larger structures with a greater amount of head-room, and in such cases excellent crops can be obtained. I would hardly recommend frames or pits for the earliest sowings of French beans.

In deciding as to the number of kinds of vegetables to be grown, the controlling factor must be, of course, the extent of the equipment. A common mistake is to attempt too many. A great deal can be done with surplus sashes and rough boards, particularly when the year is more advanced. The chief point is to make provision for the kinds which are most acceptable, or those which the circumstances permit to be well grown. Some employers are given to adopting the unreasonable attitude of demanding a good deal in the way of choice produce, but only with difficulty can they be persuaded to provide the necessary conveniences for producing them, or, if these exist, they perhaps sternly object to their being used for growing vegetables. It is singular how those who say they care nothing about vegetables invariably have more than their share of the choice ones.

French Beans.

The first sowing of these may well be in seven or eight-inch pots in a house on a shelf near the glass, where a night temperature of 55 to 60 degrees can be maintained in severe weather. The soil should be rich and light, and six or seven seeds can be sown in each pot. The syringe must be used freely, except when the plants are in flower. With later sowings there is no necessity to discontinue or at least reduce the syringing when the beans are setting, but with these earliest batches I have noticed that heavy syringing reduces the crop. The same happens with peach blossom. It is no doubt due to the better circulation of air later on in the season. In the case of beans their position in the house may also affect the setting.

I hardly think the top-dressing of beans as generally practised pays in the case of these early sowings made in January. Frequent feeding with soluble nitrogenous food gives the better result. Later on, when root action is more extensive, and the

THE DELL IN NUNEHAM PARK GARDENS.

In the foreground is a group of Pink Pearl rhododendron; beyond are the bog and water gardens; and in the distance is the River Thames.

crops are heavier, something may be said for a rich surface dressing.

If a phosphatic manure is mixed with the soil, use a high-grade superphosphate, or dissolved bone in preference to bone-meal. Where ample head-room is available the climbing French bean is a good cropping variety. The growths should be allowed to attach themselves to strings running up to the glass. Trained vertically, the plants grow better than when trained on an ordinary wire trellis.

Successional sowings can, towards the end of February or beginning of March, be made in heated pits over a little manure and leaves, or larger beds can be made, and frames placed over them. Six to nine inches of light soil should be placed on the beds. Plants from these sowings grow more strongly, and should be given more room—one foot between the rows and nine inches to one foot between the plants. A catch crop of a small-growing radish, as Carmine Olive, may be sown between, taking care to sow thinly—at least one and a-half inches between the seeds.

Most crops of radishes are spoilt by thick sowing. Later sowings of beans can be made in frames cleared or about to be cleared of lettuce.

If the soil was well prepared for the lettuce it will only be necessary to dibble the seeds in singly a foot or thereabouts each way, or they may be sown in small pots singly in readiness for frames just cleared. Among French beans there are few kinds better than a good selection of Osborne's Prolific for early use, though Ne Plus Ultra, Progress, and Bountiful are all good.

Cauliflowers.

At Reading we rely for our earliest crop in the open on a sowing made in the first half of September in a cold frame. Several thousands are potted up into large 60-sized pots when the plants are making their first true leaf. Others are pricked out into pits and frames and given a little protection during the winter.

The chief advantage arising from potting cauliflowers is that planting may be slightly delayed should the weather prove ungenial in March, as, assuming that the plants have plenty of room, an occasional feeding with a nitrogenous manure will keep them moving gently and prevent loss of leaves until better weather prevails and planting out is safe. In the case of plants pricked out in frames for the winter, it is in my experience safer to plant while of moderate size, although weather conditions may not be ideal, than wait so long that the plants become leafy, and lift with few roots. It is better to have a few cut up by cold than that the whole crop should button-in. A firm root run does something toward preventing the plants becoming gross before planting time. In some seasons no difference can be noticed between potted and pricked-out plants if the latter are carefully lifted. Those who have warm borders can, of course, plant earlier than is advisable here, where we have no friendly wall to break cold winds. We have usually reached the last few days of March before we can safely plant here. Covering up at night with pots is hardly practicable.

Cauliflowers when pulled before peas are plentiful are a very profitable crop, and well worth a little extra care. Some of the plants from the autumn sowing may be planted out in early February in frames over a shallow bed of manure and leaves covered with nine inches of soil trodden firmly. They may be placed fifteen inches apart each way, and can be intercropped with lettuce and radishes. The lettuce must be good, sturdy plants of a small, quick-growing cabbage type, and the radishes sown thinly as before. If the cauliflowers are planted on the square one lettuce can be planted in the centre of each square formed by four cauliflower plants. The pit or frame should, of course, be sufficiently deep to accommodate the cauliflowers when fully grown.

Generally speaking, for frame culture the small forcing type of cauliflower, sown in January, is the most suitable. The heads are small, it is true, perhaps too small for market, but they need less room, and are acceptable on a private table. With these it is absolutely necessary to avoid a check at any stage, or they are certain to button prematurely. On mild hotbeds, and with careful treatment in the early stages, they answer admirably. I believe some gardeners plant outside on warm borders in early April, after having hardened the plants, but with myself they have seldom done any good in the open, raised either in September or January. The best varieties for autumn sowing are Magnum Bonum, Purity, and Pearl, and there are a few good stocks of Erfurt and Early London worth growing. These, treated as advised, generally finish in the open before the middle of June, as pulling commences the last week of May. The early-forcing kinds sown in January and grown in frames turn in just before.

The soil here is a warm, light loam, and growth is particularly rapid when once really genial conditions prevail, and the plants are occasionally assisted with light doses of nitrate of soda. We have regularly realised 2s. to 3s. per dozen, and occasionally 3s. 6d., for the early outdoor crop, but unless cleared before outdoor peas come in, the latter spoil their sale.

Cucumbers.

There is no gain in earliness by sowing these before the New Year, and where the conditions are such that it is difficult to keep up the requisite temperature it would be well to defer sowing until the end of January.

It is true that stunted cucumbers recover more readily than plants of melons, but even then time is wasted when the plants are merely existing.

Much may be done in houses insufficiently heated by augmenting the warmth obtained from the piping by well-prepared beds of fermenting material, but for the earliest supplies, at the end of March or beginning of April, a well-arranged house with ample pipe heat is greatly to be preferred. In some cases it may be necessary to increase the bottom heat, where piping in this respect is limited, by the addition of a little fresh stable manure.

A somewhat holding, calcareous loam, to which, perhaps, a little lightening material in the shape of decayed manure has been added, has given the best results in my own case. Diluted blood and blood manure have proved valuable stimulants. Frequent waterings with nitrate of soda has a bad effect on the surface soil, and the feeding roots seem to perish where it is frequently used.

I prefer the cordon system of training. The point of the leading shoot is rubbed out when it is three or four feet up the trellis, the laterals are stopped at the third leaf, the sublaterals at the first. The plants are set out three to four feet apart about a month after sowing. If growth is to be rapid the night temperature should not fall below 65 degrees.

Frequent but light top-dressings give better results than heavy ones, and the older leaves must be systematically removed in order to allow the light to reach those developing on the bearing shoots.

For general use a good stock of the Telegraph variety is as good as any.

F. DREW.

HOW ALTITUDE AFFECTS PLANTS.

Though one of the most important factors that influence plants is soil, as every gardener knows, there are others that are equally potent in causing plants to flourish or the opposite. Amongst these are climate, rainfall, and temperature. But in a small country such as this these factors vary less, perhaps, within a limited area than another factor which has a very great influence on plants, and that is altitude. As everyone who has visited Western England knows, altitude in that part of the country varies immensely within comparatively short distances.

Many experiments have been made upon the effect of altitude upon wild and cultivated species, and the result has been to show that it is of extreme importance in influencing variation. There are, moreover, two objects in view in cultivation—preservation of some acquired characters in a plant found to be of use to man, as in the case of cereals and vegetables, and variation, which is a feature encouraged by the plant-breeder in the case of flowers.

It is, therefore, of the highest importance to know at what altitudes the different types of plants flourish best—i.e., retain their hereditary characteristics. The grower of oats knows, for instance, that he can grow them best at high altitudes, whilst corn grows best up to 1,000 feet, but not so well higher, where oats will flourish. An indication of this is afforded by the usual habitat of wild forms allied to the oat, which flourish best at high altitudes.

To the gardener in the ordinary sense altitude is of little significance, for he cannot in the limited area within which flowers, etc., are grown, vary the altitudes of the plots devoted to his plants. But he can at at the outset inquire what plants will best grow at the particular more or less uniform height at which his garden is situated, so that this information is of equal value to him, though it necessitates his growing plants confined to one range of altitude—more or less.

With the landscape gardener, or those who can practise the growing of plants at considerably different altitudes that may be represented upon the property under their care, the case is different, and it is to this last group that the general observations here made will have special interest.

In general there are two main zones of altitudes determined by the degree of temprature (which is correlated with altitude to some considerable extent) of each zone, the Arctic and the Agrarian, which last is defined by the altitude at which cereals will grow. The first is divided into three zones, which support the plants growing on our higher mountains, plants which are of northern origin; whilst the latter, also divided into three zones by Watson, are made up of chiefly southern plants.

In the Infer Arctic zone (1,800—2,700ft.) trees are more or less absent, and the plants are dwarf, the vegetation being characterised by such subjects as ling, heather, whortleberry, cowberry, cotton grass, etc. Here saxifrages flourish, as does the juniper. Between 500 and 1,000 feet the baneberry, rosebay, birch, cherry, rowan, London pride, Cicely, and hawkweeds grow, as on the Pennines, which includes in part the mid-agrarian zone, or that of the greater part of Central England and the east and south counties, down to the sea-level.

There are, of course, several groups of altitudes that we may recognise which are characterised by special types of vegetation, such as the coast-line, the alluvial plains rising above the river levels, plains ascending from the last, the slopes of hills,

hills up to 1,000 feet, others from 2,000—3,000 feet, 3,000—4,000 feet, and so on.

The emphasis which these facts deserve will be best brought home to those who desire to work on right lines in establishing parks, plantations, shrubberies, alpine gardens, and especially landscape gardens, by a few examples of wild plants and their habitats in this country, according to altitude. For acclimatised plants grown in this country will follow more or less closely the requirements of allied indigenous species in course of time, and the best results will accrue in such cases by a study of the altitudes at which British species are found to flourish best under normal and proper conditions.

Commencing with the lowest levels we have the plants that grow along the sea coast, or on alluvium of rivers flowing into the sea. Of these a few are yellow-horned poppy, scurvy grass, sea-kale, sea holly, samphire, absynth, sea lavender, thrift, sea milkwort, sea purslane, saltwort, golden dock, asparagus, tyme grass, growing up to a height of 25 feet above sea-level, and on alluvium at the same level crocus and small-reed. Many of these wild plants are quite worthy of a place in garden, shrubbery, or plantation, and with the object of furthering this principle we have selected those wild species which are especially suited for this purpose.

At altitudes ranging up to 50 feet grow wallflower, sea campion, stork's bill, rest harrow, water violet, yellow wort, henbane, arrowhead, flowering rush, marram grass, chiefly maritime or alluvial plants. It is needless to say that water plants are equally affected by altitude as land plants. The white and yellow water-lilies, white campion, corn cockle, mare's tail, cornflower, chicory, toadflax, Star of Bethlehem, and the reed grow at heights varying from sea-level to 100 feet. All of these are fit for cultivation. Creeping loosestrife, frogbit, sweet flag, all choice flowers, range higher up to 150 feet; and hellebore grows between 100 and 150 feet. The soapwort, needle furze, chamomile, yellow loosestrife (often seen in the garden), belladonna, vervain, and reed-mace may be grown up to 200 feet, and the bird's nest orchid grows between 100 and 200 feet.

Melilot (with its scent of new-mown hay when dried), elecampane (a handsome yellow composite), yellow Archangel (a woodland plant), grow up to 250 feet, though the last may range higher.

The barberry ranges up to 300 feet, as do the sweet violet, touch-me-not, dropwort (often cultivated), livelong (a saxifrage), sawwort, comfrey, the common elm, and the bulrush. Elms are often planted higher, but do best at low levels, a point worth knowing. Green hellebore and spurge laurel, often planted, may be grown between 50 feet and 300 feet.

A. R. HORWOOD.

Leicester Museum.

(To be continued.)

Caladiums.—Where an early batch of these beautiful foliage plants is required, a number may be selected from the earliest ripened tubers, shaken from the old soil, and placed an inch or two apart in pans containing a mixture of leaf-mould and sand in equal parts. Place in a light position at the warm end of the stove, and spray occasionally when the weather is fine. In a short time they will emit new roots and stout growths. They may then be potted according to the size of tuber, using a compost of loam, leaf-mould, and peat, with sufficient sand to keep it open. Avoid overwatering, but at the same time care must be taken that they do not remain dry, or failure is bound to ensue.—H. PRIME, Hatfield House Gardens.

SINGLE CHRYSANTHEMUMS: THEIR USE AND ABUSE.

During the past few years, probably eight or ten, single chrysanthemums have been rapidly making their way to the forefront for decorative purposes during the autumn and winter months. That they have many admirers (myself included) is very evident, if only from the fact of the many new varieties that are introduced each season.

SINGLE CHRYSANTHEMUM MRS. LOO THOMPSON.

A beautiful yellow sport from Mensa, introduced by Mr. Norman Davis.

Characteristics.

There are individuals who would have us believe that every other class of chrysanthemum is doomed, and that at no very distant date; but I am of the opinion that the single chrysanthemum is now at the zenith of its popularity. We have varieties that it seems almost impossible to supersede either in size, colour, or form, and when you have a variety, in any particular colour, well-nigh perfect in form, there is not much more that can be expected. Directly a single chrysanthemum loses its straightness of petal its beauty is entirely lost, even if only two or three petals are displaced it looks more or less ragged in appearance. If the petals happen to be naturally a little out of the horizontal and slope or grow upwards ever so little, one cannot by any stretch of imagination call them beautiful. I might perhaps modify this remark a little in favour of that old favourite Purity, which incurves just a little at the point of each petal, and has a very pleasing and distinctive appearance. On the other hand, if the petals recurve or hang down a little, unless one knows the variety, they are apt to convey the impression that the blooms are flagging.

Some take an exception to the single varieties that have a large striking disk. Certainly, in a few instances where the disk of the flower is very large and comes distorted it may be objectionable, but,

generally speaking, I do not agree with this point of view, providing, of course, the disk is not out of proportion to the length of the petals and the colour contrast is not aggressive. In many instances the disk is quite the making of the flower.

Disbudding.

As mentioned above we have varieties of single chrysanthemums that are excellent in every way, but to have them at their best they must be given the same consideration as you would give a Japanese variety, and not be grown in the haphazard manner of stopping, say, twice in the young state, to induce a bushy habit, and then allowing them to grow and flower at will. This method of cultivation might well be termed one of the abuses of the single chrysanthemum, and, although such might please a certain class of people who want plenty of flowers for filling vases, it does not satisfy the person with an artistic sense or love of flowers. It is the one thing before all others that will undermine the popularity of the flower, for under such cultivation the stems are not stiff enough to hold the flower fairly erect, the foliage is not of sufficient substance to either show the flower off to advantage or to withstand the slightest variation in temperature without it shrivelling up or being covered with mildew. Moreover, the flowers will not keep half as long as will those borne by plants that have been disbudded and well grown.

There are, however, many varieties that are not so good on the disbudded system, such as Mary Richardson, Dorothy Dann, Ideality, Jack, Miss Mary Anderson, and Nellie Riding. These varieties should not be stopped more than once (and this is not necessary), the wood has then time to mature somewhat, and the sprays of bloom are held more erect. The blooms are better in quality, and certainly will last longer in water without losing colour.

Good Culture Essential.

Good, well-grown, disbudded flowers have certainly much to recommend them. On the plant they are most effective and compare much better than do the floppy sprays with some of the good types of decorative Japanese. Moreover, when cut they may be used with advantage in all kinds of decorative schemes, either by themselves or in conjunction with their more imposing neighbours, the medium to large-flowered Japanese varieties. It is, indeed, in association with the latter that they are seen to the best advantage, the rotundity of the Japanese varieties often filling in a gap in a decorative scheme where a single flower would not be so effective. With regard to this point, it must be acknowledged that the profile of a single bloom is not nearly so beautiful as a fairly well-developed Japanese or incurved flower, however small. But as suggested when referring to disbudding varieties must be grown well to obtain the greatest value from them, either as cut flowers or as pot plants. I am not supposed in this article to deal with the cultural details, but I cannot help repeating what I have often written respecting the single and decorative chrysanthemums, that they should be grown quite naturally from the cutting until they show flowers, when they may either be allowed to flower naturally undisbudded or be restricted to one bloom to each shoot. Under such treatment they will perfect more flowers than under any other system of cultivation.

For very dwarf plants I do not recommend this method of procedure, as a system of stopping to keep them dwarf must be adopted, and if suitable varieties are chosen they are very effective. Certainly, one of the best uses to which single chrysanthemums can be put is their cultivation in small pots. I do not suggest the starving of plants that have been raised from cuttings struck in the early spring, in 32's or small 24's, but plants raised from cuttings rooted during May and June, and shifting on into 48's only. Allowed to grow naturally, with good treatment, they may attain a height of two feet, and are just what one would term a huge spray in a small pot. If fairly stiff and free-blooming varieties are chosen, such as the Pagram family, Mensa, Brightness, Mrs. Tristram Gilbey, Merstham Jewel, Jack, Sylvia Slade, Miss May Thorne, or Hilda Lawrence, they will be found most useful.

New Varieties.

Probably the greatest abuse in connection with the single chrysanthemum has been, and still is, the indiscriminate introduction of new varieties, for since they became popular, it seems to have been the aim of everyone to cross-fertilise varieties regardless of their merits, and send the whole of the progeny out instead of making a rigid selection from them. This has, to my knowledge, made many lovers of the flower very chary of buying novelties, and harm has thus been done to the trade generally. The National Chrysanthemum Society have no doubt set a very high standard in making awards to single chrysanthemums (which, by the way, are so very easily raised), and if buyers were to take these awards as their guide when purchasing new varieties, they would not fail to obtain more satisfaction from the single chrysanthemums. I cannot help feeling that we should be much better off if we could start afresh with, say, thirty or forty of the very best of the present-day varieties.

Select Singles.

During the past season the awards to single varieties have been fairly numerous, but in most instances I am sure the varieties are of special merit, and certainly that delightful yellow sport from Mensa—Mrs. Loo Thomson, of which an illustration is given herewith—is a great acquisition. It has all the good attributes of its parent, and is pleasing and effective in colour. A few other varieties that have been made note of during the season are Sussex Yellow, Ideality, grand for sprays; Rosemary, White Beauty, Sydney Lawrence, Mrs. Gertrude Ladds, Miss Margaret Walker, Portia, Snow Queen (anemone single), Mrs. Roger Gregory, and Joey Saunders. Add to this list the Pagram family, Mensa, Merstham Jewel, Ceddie Mason, Sylvia Slade, Charles Kingsley, Snowflake, Hubert Williams, Mrs. W. G. Patchling, Mrs. Higgs, Marjorie Lloyd, Brightness, Miss Mary Pope, and Mrs. Tristram Gilbey, and we have a collection that might almost be termed perfection in every way, especially under such cultivation as Mr. Norman Davis, Mr. Ladds, and Mr. Cragg give them. They are as useful as they can possibly be, but even under such conditions they are not quite up to the same standard as well-grown decorative Japanese varieties. They do not pack so well, neither do they last so long when cut, and certainly on the plant they lose colour rather more quickly, and this is the reason I am apt to think that they will not become more popular than they are at the present time. I must, however, add they have given a fillip to the trade at a time when it has been suggested that our large exhibition Japanese are going out of favour, but I hope the time will not come when either of the two classes is not equally as popular as now.

T. STEVENSON.

BEDDING PLANTS FROM EARLY-SOWN SEEDS.

An increased amount of attention has been directed within the past few years to the charming effects produced by plants that are annually grown from seed, in contradistinction to the older types of bedding plants. Not that these can be dispensed with altogether, yet, at the same time, it is questionable if any plants give more pleasure than do those now so popular that can be raised from seed sown early in the year.

Various notes on this subject have from time to time appeared in the GARDENERS' MAGAZINE, and it is doubtless largely due to the appearance of such articles that the public taste has turned in this direction of flower garden decoration. Of late years many of the older and formerly accepted axioms regarding plants to be used in beautifying the flower garden have been entirely reversed, as have been amply exemplified by the examples in many of the public parks and gardens.

Raising Seedlings.

Plants formerly considered unsuitable, or unable to be raised from seed, have, under proper treatment, proved to be most suitable and highly attractive, and are increasing in numbers year by year. Most of the kinds that will be named in these brief notes may be raised in gentle heat from about the end of January onwards; with the soil kept uniformly moist germination, with the assistance of a temperature between 60 degrees and 65 degrees, will soon follow. The mixture used in filling the pots may be composed of loam and leaf-mould in about equal proportions, with a liberal addition of gritty silver sand. The whole should be passed through a half-inch mesh sieve, reserving the coarser portions for placing over the drainage in the pots or pans. That used for covering the seeds should be still finer, where any covering is necessary.

When the seedlings have produced their first pair of rough leaves they should be placed on a shelf or in a heated frame not far from the glass. Thus treated they will be short-jointed and strong. No attempt should be made to hurry them by subjecting them to much artificial heat. An increase of ten degrees by sun heat will do no harm while in their young stage of growth. When the seedlings are large enough they may be carefully transplanted singly into small pots, or into pans or boxes; in the latter case they should be put about two inches apart each way, using a similar compost as formerly, but a trifle coarser in texture.

Preparing the Plants.

Under these conditions the plants may be allowed to grow until they are placed in their final-sized pots, and when established in these they should be gradually inured to a temperature somewhat lower, and finally hardened off prior to being planted out. Dwarf, yet strong growth must at all times be aimed at, which may be accomplished by a free, yet judicious admission of air to the plants upon all favourable occasions.

At no stage in their growth must the plants be allowed to suffer from an insufficiency of moisture at the roots, or a serious check will be given them, for, as a rule, if young and tender plants are brought to a standstill by careless treatment, they cannot be induced to start again into growth for a long time. During bright sunny weather, whenever the plants show signs of distress, a gentle spraying with clear

water overhead, and the addition of a little shade for an hour or two, will prove of great assistance to them.

Should green-fly or other insect pests attack the plants—which is rare if they have been kept steadily growing—they should be lightly fumigated, or sprayed with an approved insecticide, otherwise they will soon become disfigured.

Kinds of Special Value for Bedding.

Antirrhinums are now frequently employed for bedding, and are thoroughly reliable and effective for that purpose. The Tom Thumb, Intermediate, and Grandiflora types may now be obtained in distinct colours, and are most effective when massed together, and their heights graded according to the position they occupy. All these should receive cool treatment, after being transferred into their final pots or boxes.

Begonias of the fibrous-rooted type are in many places superseding those of the tuberous section. These are so reliable as showy bedders and last the season through without a break in flowering, that few would venture to do without them. Magnifica, flowers bright carmine, and golden-yellow stamens; Crimson Bedder, flowers crimson, with beautiful crimson-bronze foliage; Fairy Queen, flowers silvery-pink, with bronzy-green foliage; Semperflorens, flowers white, shaded pink, with light green foliage, are all desirable varieties, forming dwarf compact plants.

Begonia seed, after being sown, should not be covered with soil, but care should be taken to thoroughly moisten the soil before the seed is sown, after which the pans may be covered with a sheet of glass, with a layer of damp moss on the top of the glass. Watering of the soil should not be necessary until after the seedlings appear, then water sparingly for a time, otherwise the tender seedlings will damp off.

Dahlias of all the well-known types are easily raised from seed, germination taking place very quickly. All these will bloom the same season in which they are raised, and form good-sized tubers for the following year. The double varieties are generally somewhat later in flowering than are plants that have been raised from cuttings, but much depends upon the treatment they receive, and the position the plants subsequently occupy.

The single and star varieties usually flower most profusely at an early stage of growth, and continue doing so until cut down by frost. Very beautiful and striking varieties may be raised, equal in every respect to many of those that have been selected for distribution under names.

Verbenas are general favourites, and may be raised from seed fairly true to colour. Care should be taken to procure new seed, or many of the seeds will fail to germinate. It is the rule with some growers to sow the seed during the autumn as soon as it is ripe, or is obtainable from the seedsman, wintering the seedlings in a greenhouse or slightly heated frame. Others sow the seed as soon as possible in the New Year, growing the plants steadily on until required for bedding out, a practice we ourselves follow. At all times the soil in which the plants are growing should be kept uniformly moist, otherwise the foliage will quickly become a prey to red spider or mildew. A genial temperature, with an abundance of air, is the proper conditions under which these plants should be grown.

Unless the position or locality be very cold or exposed verbenas may be planted out fairly early in the season with safety, the plants quickly become established in their new quarters, and make good progress before the very hot weather is experienced, after which they simply luxuriate in the sun and heat, flowering most freely. The giant auricula-eyed is a very showy type, giving a wide range of colours, each flower having a large white eye, or centre; a bed of these always makes a very attractive display. Scarlet, white, blue, pink, and purple shades may also be grown fairly true from seed. For cutting purposes all of these are useful.

Salvias as bedding plants are most showy and useful, blooming very freely. The old Salvia patens should find a place in every garden, however small; planted in conjunction with dwarf African marigolds, yellow calceolarias, Fairy Queen begonias, or Madame Crousse ivy-leaf pelargoniums, a very telling effect is produced, a combination of colour not soon forgotten. The newer types of bedding salvias such as Glory of Zurich and Fireball for an early display, followed by Queen of the Scarlets, are alike invaluable where a bold, bright display of colour is desired. Care, however, must be taken to keep the plants well supplied with moisture, both at the roots and overhead, during spells of hot scorching weather, or the foliage will become permanently disfigured by red spider, a pest very difficult to eradicate when once it makes its appearance on these plants.

W. HEDLEY WARREN.

Aston Clinton Gardens.

THE BORDER LINE IN APPLES.

An article upon dessert apples would not, in my opinion, be sufficiently comprehensive without some reference to the several splendid varieties, which, under the generally-accepted rules provided for the guidance of both exhibitors and adjudicators, are included in the culinary classes. That some such distinction is necessary all must admit, and its adoption has very largely done away with the quibbling and adverse criticism formerly so prevalent at large fruit exhibitions.

In the dining-room, however, these rules may be generally disregarded, as all are free to exercise their own taste and opinion upon the contents of the different dishes, and some persons prefer a firm, rather sharp flavoured fruit to the very best of the dessert kinds.

In some respects, this is fortunate rather than otherwise, as it enables large handsome fruits to be displayed, though not of the highest quality, without any serious thoughts being entertained as to their fitness for the purpose, and not unfrequently such elicit higher commendation than do their more delicately-textured compeers. Apples of this class are, as a rule, more vigorous in growth, and consequently somewhat hardier than the true dessert varieties, and thrive in the open as bush or standard trees, and mature crops almost as well as under more favoured conditions as to warmth and shelter.

Twelve Good Apples for Either Dessert or Kitchen Use.

White Transparent.—Early in the season, generally about the middle of August, this variety gives evidence, by its gradually assumed sulphur colouring and delicious aroma, that its qualities are developing. It is best consumed a few days after gathering, as it loses both colour and flavour rather quickly; but, taken at its best, it furnishes a pretty dish among the predominant red-tinted ones then ripe or ripening.

Cox's Pomona.—A showy, crimson-coloured fruit that keeps well, and has a very agreeable flavour.

The Queen.—A large and very handsome variety, which thrives well as a bush-trained tree, and is not subject to canker or other diseases. This apple is fit for use as a dessert fruit from the middle of October onwards, and is much favoured as such.

Golden Spire. — A peculiarly shaped fruit, that assumes a beautiful golden-yellow colour while yet upon the tree, and its piquant flavour is much appreciated by some persons.

Emperor Alexander.—This well-known apple requires but little describing further than that in former times it more frequently than any other formed the chief point of contention as to the class to which it belonged. The soft white flesh of this makes it passable for dessert.

Peasgood's Nonsuch. — Probably, the finest apple in cultivation, if form, size, and colour are all considered, and its qualities are very good.

Charles Ross.—A smaller counterpart of the foregoing, and a particularly handsome fruit.

Blenheim Pippin.—This famous Southern apple does not commend itself very highly to Northern growers, as it is long in reaching the bearing stage, and a rather shy fruiter afterwards. Grown against a wall, upon the paradise stock, these defects are largely eliminated.

Gascoyne's Scarlet Seedling.—A beautiful crimson-coloured fruit, more especially so when pains are taken to ensure full exposure to the sun. In Northern parts it deserves the shelter afforded by a wall, when in appearance and quality it is scarcely surpassed by any other kind either for cooking or dessert.

Graham's Royal Jubilee.—The value of varieties that assume a rich yellow tint when ripe can scarcely be over-estimated, and this is one of the best of such. It also possesses size, shape, and high quality, and remains good for a long season.

Lady Henniker.—A fruit of rather angular outline, large, and generally richly-coloured. The tree is a strong grower, and a fairly constant cropper if means are taken to reduce the superabundant number of fruits in very favourable seasons.

Galloway Pippin.—This is a very old variety, having been cultivated in the province of Galloway for centuries under the name of Croft-an-Reigh. Here we rely upon it for late supplies almost entirely. This preference may be partly accounted for owing to the fact that more trees of it are cultivated than of any other variety. Apart from this, none others keep so sound and prove so reliable for the dessert during the months of April and May. The fruits are shapely, of medium size, and become a beautiful yellow colour as spring advances, while for juiciness and spriteliness of flavour it has but few equals in its season.

JAMES DAY.

Galloway House Gardens, Wigtownshire.

Clivia Gardeni.—By far the best-known of the clivias is C. miniata, which forms such a striking feature in our greenhouses during the spring months. When not in bloom C. Gardeni greatly resembles C. miniata, but from a flowering standpoint it is far less showy. It is, however, valuable from the fact that it blooms towards the end of the year, when flowering plants are much less plentiful than they are during the blooming period of Clivia miniata. The flowers of C. Gardeni are borne in large umbels, are pendulous, and about a couple of inches long. They are tubular, and in colour red and yellow.—W.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

THE GENERAL WORK in the orchid houses will now begin to increase, and many of the subjects in the different departments will require repotting. It is not advisable to disturb plants more than is necessary until there is some prospect of reducing the use of artificial heat. It is desirable therefore that everything should be done now that will facilitate work at a later period. Any inside cleaning should be attended to, and in districts where fog, smoke, and other impurities of the atmosphere leave a deposit on the outside glass, considerably excluding the light, it is advisable to wash the outsides of the roof at reasonable intervals. Peat may be pulled and put ready for use, and the sphagnum moss picked and washed. Where leaves are used in the potting compost, the present affords an opportunity of securing them. Beech and oak leaves will have collected together in large quantities after the recent high winds, and they may be obtained dry and free from pieces of wood. Where it can be conveniently done, it is advisable to sterilise the leaves by passing steam through them, or even baking them, to kill insect pests, etc.

PESTS.—Speaking of insect pests reminds me of the desirability of laying traps for cockroaches and woodlice. If some hollowed-out potatoes are placed about the stages many pests may be caught and destroyed at night with the air of a lamp.

DAMPING THE HOUSES.—Maintaining the required moisture in the atmosphere is undoubtedly one of the principal considerations in successful orchid culture. The excessive use of artificial heat is generally found to be detrimental, and care is required to minimise its evil effects as far as possible. No hard and fast rule can be laid down, because the conditions and positions under which orchids are cultivated are so varied. I have always found that where a low temperature prevails for any lengthened period outside, that we may safely resort to a temperature below the normal in the houses, providing there is a corresponding reduction of the amount of moisture in the atmosphere. It is immediately after these periods that the ill-effects become apparent, and to prevent shrivelling as far as possible a close watch is necessary, so that as soon as the normal temperature is reached the needful moisture may be at once supplied to the atmosphere by damping. In milder weather there is also a tendency to an excess of moisture unless the atmosphere can be kept moving, and this is best managed by a careful use of the ventilators, using those on the sheltered side of the house first, and, if the temperature permits, those on the opposite side may be opened slightly later on, but care must be taken to guard against draughts.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

TEMPERATURE AND ATMOSPHERE.—The temperature of the stove should at this season range from 60 to 65 degrees at night, and from 65 to 70 degrees by day, allowing a rise of five degrees or so when the weather is mild. At such times a little ventilation from a short time before noon until a little after may with advantage be given. Damping down floors and stages will be necessary only once, or at the most twice, during the day, and for the present the plants will be better if the use of the syringe is withheld or reserved for those occasions when the weather is bright and mild.

THE STOVE FLOWERING-HOUSE.—In the warm flowering-house, where we have at present Euphorbia jacquinæflora, poinsettias, winter-flowering begonias, gesneras, Coleus thrysoideus, saintpaulias, isolomas, etc., a temperature of 55 to 60 degrees, rising on mild days to 65 degrees, will be sufficient. Here the atmosphere should be somewhat drier than in the stove, and a little ventilation may be afforded whenever 60 degrees is exceeded.

CLEANLINESS.—That cleanliness is essential to the well-being and good cultivation of plants goes without saying. At this season, when the demands of Christmas decorations, have left some of the pits and plant houses somewhat relieved of many of their occupants, a good opportunity is afforded for removing some of the inmates of the stove for the purpose of thoroughly washing and cleansing the house. Permanent climbers should be carefully pruned and temporarily removed from trellising or rafters. Allamandas may be pruned hard, while Clerodendron Thomsonæ, stephanotis, Hoya carnosa, Cissus discolor, etc., should be relieved of superfluous old or weakly growths, leaving sufficient strong, nicely ripened growths for re-covering. The whole of the woodwork and glass should be well cleansed by the use of soft soap and water, while, to ensure as far as possible the destruction of insect pests, a little paraffin may be added to the water. Carefully wash, through a fine sieve, the granite, or fine gravel, with which the stages are covered. Thoroughly clean beneath the staging, and let the walls be limewashed. After cleaning them the climbers may be replaced; necessary sponging of pot plants, and pot washing, should follow, and the whole house be rearranged. The propagating frame should also be cleansed, and old plunging material replaced by new.

B. GLOIRE DE LORRAINE and its varieties, as they pass their best, should have their flower spikes removed, retaining about two-thirds of the foliage. These may also be given a short rest by keeping them rather drier at the root with a view to starting them into growth for the production of cuttings in March and April.—H. PRIME, Hatfield House Gardens.

FRUITS UNDER GLASS.

MELONS.—Where efficiently heated pits will soon be ready for these plants, a few seeds of good early varieties may be sown this month. Melon seeds may be sown singly or in pairs in small pots or on squares of turf, where they can have a bottom heat of 75 degrees, with full exposure to light, removing the weakest plant when the seed leaves have developed. Where fermenting materials are used, a good supply should be prepared so that everything is in readiness when wanted. A good start, with everything fresh, sweet, and clean, is more than half the battle; the pits should be thoroughly cleansed—glass, woodwork, and walls. If the plants are grown in 12-inch pots, which I prefer, the pots may be plunged where they are to remain; or, better still, set them on inverted pots to prevent sinking, and possible strangling of the plants later, putting the fermenting material round them. Crock well, and place the roughest of the compost at the bottom of the pots; use a fairly heavy loam and lime rubble, with a little bonemeal, and make it fairly firm. If planting out is preferred, a similar compost placed upon turves, grass side downwards, in the form of a ridge, will answer equally well, but unless the hot-water pipes are equal to maintaining a bottom heat of 75 to 80 degrees, the pot plants will be ready first. A night temperature of 65 to 68 degrees, 75 to to 85 degrees by day, with sun heat; and a moist atmosphere secured by frequent sprinklings, will be found suitable.

STRAWBERRIES.—Some growers start their first batch of plants in December; the majority start with the New Year. Fire heat has not been necessary with few exceptions, to keep up the moderate temperature of 40 to 45 degrees required, with a few degrees higher by day. Where brick pits are available, a sweet, moist heat from fermenting leaves is best for starting strawberries, as this gently stimulates the roots and prevents early attacks of red spider. As the plants come into flower they should be placed thinly in the lightest part of the strawberry house, where fresh, warm air can circulate freely among them. A number of the small, weak, side blooms may be picked off with advantage before the flowers open.

VINE EYES.—If planting new vineries or the renewal of old ones is contemplated, a sufficient number of eyes should be collected during pruning, labelled, and laid in until required. Where a suitable pit or house is available, the required number of eyes may be put in this month into small pots, or preferably on turves, as the roots do not then get cramped. It is best to defer the start till next month, or even later where no proper house is available, as when the days increase in length rapid growth will justify the delay, and good young vines will then be ready for planting out in June.—F. JORDAN, Warter Priory Gardens.

THE FLOWER GARDEN.

THE PAST AUTUMN, with its normal rainfall and mild weather, was tolerably favourable for ground work generally, and as a result this is in many instances well advanced; but from various reasons, much often remains to be done in the New Year. Every advantage should be taken of open weather to proceed with these operations, for with the lengthening days comes much work requiring attention. Where it has not been possible to finish any alterations in connection with herbaceous borders, no opportunity should be lost in completing the same, as no other part of the flower garden repays better for timely attention with respect to planting than this one. A top-dressing of decayed manure or leaf-soil will greatly assist any trees or shrubs moved recently; the latter will be most suitable for those of American origin, and as planting proceeds at this season it is important to follow up closely with a top dressing to prevent severe frosts from penetrating to the roots. Evergreens are the most susceptible to injury, and should for this reason be left wherever possible until the severest weather is past before being moved. Precaution must be taken to ward off severe frosts from any tender subjects; pieces of heather or bracken placed thinly amongst the growths will provide sufficient protection for hybrid tea roses, myrtles, carpentarias, etc.; but for others, such as aloysia, swainsonias, Romneya Coulteri, etc., mats will be found more efficient and convenient, but they must be removed on all mild days, as a dense covering remaining on for several weeks does more harm than good.

SWEET PEAS.—Where the practice of autumn sowing has not been adhered to, a sowing should be attended to at once, as undoubtedly the best results are obtained from early sowings. Sow the seeds thinly in pots or boxes, and place them in a cool house or pit. When the seedlings are large enough to handle, pot them off singly into small pots, and grow them on in a cold frame where they can be given plenty of air when the weather permits; on fine days remove the lights altogether. Under these conditions they will make stout growth, and will receive but little check when transferred to the open ground.

EARLY-FLOWERING CHRYSANTHEMUMS.—A collection of these popular plants is very desirable, and should be added to annually. Propagation should now receive attention; rooted cuttings are to be preferred to plants obtained by splitting up old stools, as they grow more freely. Stools which were lifted at the end of the flowering season and laid in closely together in a cold frame are now producing plenty of cuttings, and these, if taken off and rooted now, will make good plants for putting out in May.—T. B. FIELD, Wych Cross Place Gardens.

20,000 Hectares of Land for Sale in the Argentine Republic.

Abundant pasture and water. The camp is very suitable for sheep-breeding. Very good climate. On this camp there are more than two millions Pine trees "Araucaria imbricata," and which measure more than one metre in diameter. The wood of these pine trees can be converted into timber as well as celulosa. This wood renders 48 per cent. of celulosa. In the Argentine Republic exist no celulosa mills. Argentina imported during 1911 not less than 24 millions kilos of celulosa. These pine trees produce a large quantity of first-class resin. The land can be inspected at any moment, and all the expenses from Buenos Aires to the camp are paid by the seller. Ask Esteban C. Ferrari, Corrientes 685, Buenos Aires, Argentine Republic, for further explanations and photos. The price for this fraction of land, with all it contains, is 170 francs per hectare, or, say, three millions four hundred thousand francs for the 20,000 hectares. Bear in mind that the price is stipulated in francs, and not in dollars, and that the area is 20,000 hectares, or, say, 200 square kilometres, and not acres. The Railway Line runs 40 kilometres distant from the land.

MORAINE GARDENING.

There seem to be at present two schools of thought and practice in the domain of moraine gardening. The one urges the necessity of a steady supply of water for the moraine, even at the cost of a concrete base; while the other teaches that this is not essential, and that the plants can be grown equally well without the expense involved in concreting the moraine.

It is quite probable, however, that the question cannot be dismissed by saying that this or that method is the one to adopt in the construction of a moraine. Much will depend not only on the rainfall of the district, but also on what we may call the sub-soil, upon which the moraine is constructed. It is quite reasonable to suppose that a cement base may be desirable, where the district has a small average rainfall, or where the subsoil is so sandy and gravelly that the water supplied, either from the clouds, or by some artificial means, will drain away too rapidly after passing through the porous composition of the moraine itself. On the other hand, the cement may be quite useless, and may even be injurious where the rainfall is heavy; where the atmosphere is often laden with moisture; or where the subsoil is of such a nature that the water will not percolate readily through it, but either remains for a while, or runs along a decline until it finds egress. In such a case the cement is undoubtedly a waste of money and labour, and can quite easily be dispensed with.

It is many years since the writer, then living close to a shingly beach, was much impressed by the manner in which plants would thrive when growing in the gravel of the shore. It is amazing indeed to observe how strongly some of them will grow, even when there seems but little nourishment and less moisture for the roots in the free shingle and gravel, which forms their sole field of nourishment, save from the clouds above. In some cases these plants had running water flowing off the land, near their roots, but in many instances you might go several feet down before you reached moisture, save the dampness absorbed and retained by the gravel, which was often visible a few inches down. This set me thinking, and next experimenting with plants in the garden, and the general conclusion reached was that in a climate with a fair amount of rain and mist many alpines could be grown well in such a medium as this. I had also been experimenting with alpines planted in the soil, but thickly mulched with fine gravel from the beach, say, from one to three inches thick. This, also, proved very successful, and I was by this means enabled to cultivate plants which in the ordinary way would not flourish even on rockwork without the aid of the gravel. This was long before moraine gardening came to the front, and the latter has naturally been also the subject of consideration and trial.

The moraine which is an exact copy of the moraines of the mountains is not an easy thing to reproduce successfully in the garden, and it is, moreover, not the contrivance which will suit all alpines which can be cultivated on the garden moraine. Those best acquainted with alpines will realise the truth of this, and will agree that some modification of the natural moraine is needed in our climate, especially in the parts of the country with a heavy rainfall. I have made a special point of studying the numerous examples of moraine culture of alpines of various kinds, and, while not doubting that good results can be obtained by providing underground water by the use of cement and concrete, I am disposed to urge that in most gardens this is unnecessary, and in some instances even injurious. Take, for example, the silvery saxifrages, recommended for moraine treatment, and thriving amazingly under it. Some of the best examples of these favourite flowers the writer has ever seen were growing in what could be called a large "pocket," drained with stones beneath, raised above the surface, and filled with gravel, broken limestone, and a little sand. Beyond an occasional watering in continued drought these flowers received no water supply, save the rain, and they were examples of great beauty. Even some of the oppositifolia saxifrages throve and flowered admirably when thus cultivated. So, also, with campanulas, considered difficult to do—e.g., of the type of C. Allioni, C. excisa, and C. cenisia. This is only one instance out of many where the "dry moraine" became a success of the highest kind.

In my garden I have a moraine made of a thick—six-inch—layer of broken stones, about the size of large broken metal for macadamised roads, covered with about three inches of soil, and overlaid with varying thicknesses of whinstone chips, and without any special water supply. Here a number of plants have established themselves in the happiest way, and are as fine as any with the underground water treatment. Not only this, but there are plants in the garden with a "mulch" of chips, varying from one to three inches deep, and evidently enjoying their conditions. A more striking case in point is afforded by the methods adopted in a garden where many choice alpines are grown in the most effective way, though, perhaps, in a manner too artificial-looking for many of us. Box-like structures of dry built stones, just like a dry-stone wall, and about three feet high, are drained beneath with a layer of stones. On this is placed open soil, composed of loam, sand, leaf-soil, and a little old cow manure. On this again are laid about six inches of small chips, in which the alpines are planted. There is no underground water supply; there is the freest drainage, and the plants are in perfection.

The truth is that a moraine need not be made after any special fashion, provided that it is well drained, and that the upper part of the bed is free and open, so as to prevent the lodgment of moisture about the neck or crown of the plants. If those who are deterred from the provision of a moraine because of the expense or labour, will only try a few plants in large pockets, well drained, and filled with suitable material, or will even mulch some of their flowers with a few inches of chips, they will find that in many cases they need not trouble with a moraine at all. Not that one would depreciate a moraine altogether, as that forms a most pleasing and useful feature of the rock garden, one far more so, indeed, than many suppose, the chips or gravel harmonising well with the plants, and making a feature of more than passing interest where alpine flowers are cultivated and prized.

There is really no call for a battle royal between the different methods. Moraine gardening is like other methods of horticultural practice—it can be followed by pursuing different lines, yet each may give all that is required in the way of flourishing, long-lived, and beautiful flowers.

S. ARNOTT.

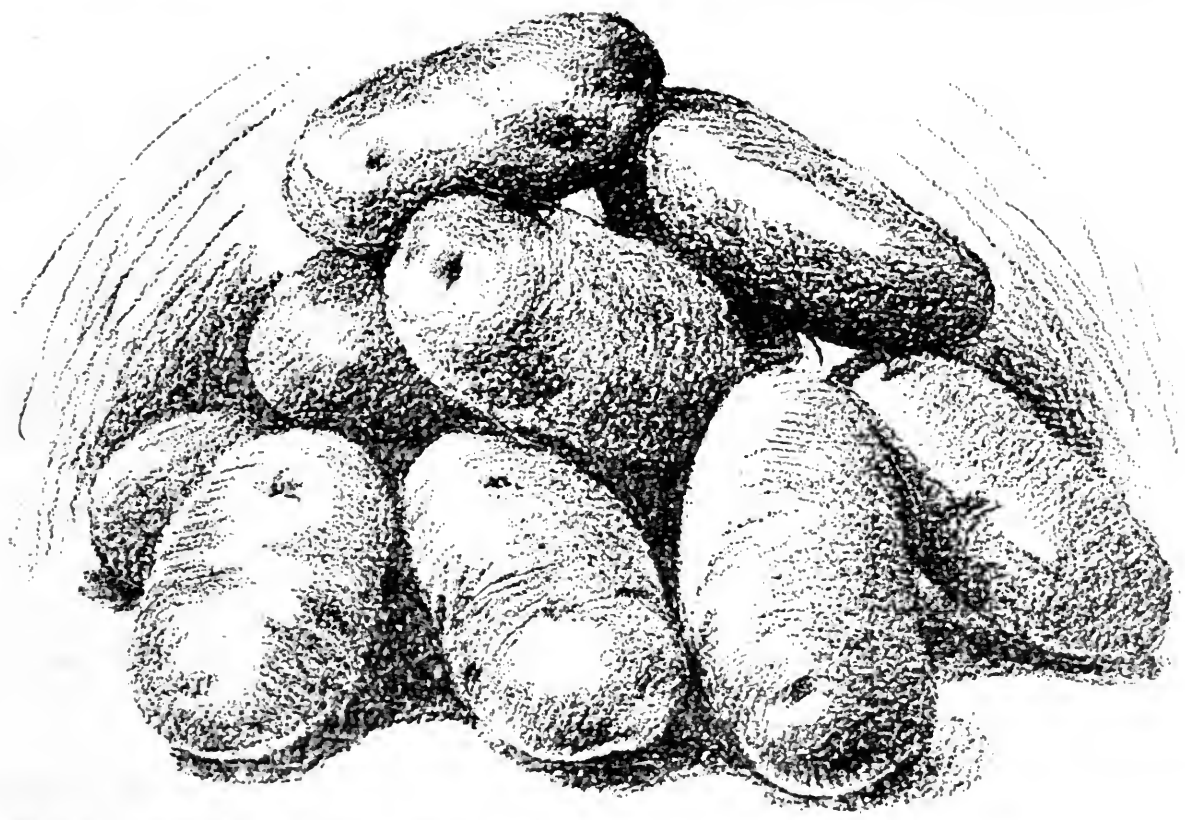
OUR CALENDAR.

We have specially prepared a number of copies of the Almanack included with this issue for Presentation to Readers.

These are printed on Superfine Art Paper—mounted on strong card, and eyeletted for hanging. The Almanack makes a charming and useful decoration for any wall.

While the copies last we shall be pleased to send one for four penny stamps—the cost of packing and postage.

Address: PUBLISHER OF "THE GARDENERS' MAGAZINE," 148-9, Aldersgate Street, London.



CLEAN UNBLEMISHED VEGETABLE CROPS

are the direct result of using Clift's Manurial Insecticide—the most potent soil fumigant. It destroys all soil insect pests, and supplies valuable fertilising properties. It is cheap and easily applied—2 to 3ozs. to the square yard is an ample dressing, and is sufficiently strong to last for two seasons.

Tins, 6d., 1/-, 2/-; 14lbs., 3s. 6d.; ½cwt., 6/6; 1cwt., 10/6; 5cwts., in 1cwt. bags, £2 10/-; ½ ton, in 1cwt. bags, £4 15/-; 1 ton, in 1cwt. bags, £9.

CLIFT'S MANURIAL INSECTICIDE.

Full particulars from ROBINSON BROTHERS, LTD., WEST BROMWICH, STAFFS.

EVERGREEN BEDS AND BORDERS.

Gardeners are devoting more attention now to the foliage qualities of the perennial plants used in the ornamental garden, for the idea is becoming current that deciduous subjects, other than the rose, should be relegated to positions in which beauty is not the first essential, and a speciality be made of such species as possess evergreen leaves. The term perpetual-leaved is, however, more suitable, since all permanent foliage is not green. Under this category, for working purposes, may be ranged also the many shrubs, etc., which do actually shed leaves, but do so gradually, new shoots being produced to take the place of the old covering.

It would be an interesting study to discover how far successful, if at all, our skilled florists have ever been in persuading deciduous subjects to attain a perpetual foliage character, and if anything is scientifically known of the reasons why certain plants of a family exhibit this valuable quality in distinction from the others; also whether the habitation, customs, or climatic influences lead to, or hinder, this development? Meanwhile, the employment of "evergreen" perennials should be the closer study of all who have ornamental grounds to plant and embellish.

Cut-down herbaceous plants, if well accompanied by permanent-leaved ones, do not disfigure beds or borders during winter, but what can be said for them during the preliminary dying-off stages? Only those persons who possess spaces filled with the superior plants know the gain to neatness and charm, and become convinced that deciduous flower-yielders, however valuable, ought to be cultivated in reserve garden stretches. Perhaps the chrysanthemum may be fairly classed among evergreens: it can be cut to the soil directly the blossom is faded, and, in all fairly genial localities, will make new basal growth and keep healthy-looking all winter.

Immediate attractiveness results from filling beds with mossy saxifrages, campanulas, including Canterbury bells, carnations, pinks, heucheras, and Iceland poppies, with arabises, double daisies, winter stocks, auriculas, and many other favourites. It should be realised that many flower beauties are not strictly evergreen, yet answer the purpose fully; also that very few of the species that give an always attractive effect can be left to their own unaided devices. German and other irises, and hart's-tongue ferns, for example, must have decayed or spoilt foliage removed in order that the new growth may be vigorous and the pleasing appearance maintained.

Beds of silver or gray-leaved plants are grateful to the eye; set in verdant green lawns they are especially suitable, since the bed shapes are then clearly defined, which is not the case when plants as green as grass are used. Iceland poppies, pinks, carnations, cerastiums, auriculas, dwarf veronicas, Stachys lanata, Santolina chamæcyparissus, and Antennaria tomentosa are among plants that generally keep their silver leaves.

Wallflowers in sheltered gardens are sightly all winter, but where cold winds sweep they cannot be relied upon to sufficiently flourish to be cultivated as foliage subjects; their appearance becomes abject after a shrivelling easterly gale. Primroses, indeed most members of the outdoor primula family, are delightful leafy subjects until scorching summer destroys the old foliage. However, when using them for portions of perennial beds, they can be rendered harmless even in droughty seasons by picking them over, and partly covering the stools with leaf-mould. Ordinary garden pinks require to have their shoots thinned out to maintain them in perfection as foliage edgings or carpets; this is often a better practice than root division. Violets are not sufficiently employed as ground coverings. Among tall evergreen plants, or small ornamental shrubs, they find the semi-shade they need, and provide a refreshing green carpet that is brilliant after a shower.

M. H.

BUILDING IN REGENT'S PARK.

The building operations that have been in progress for some time past in the inner circle of Regent's Park, have been watched with much interest by the residents in the north-west of London, and now that the buildings are rising among the trees, public interest has been greatly quickened in what is being done ,and a strong protest has been made by St. Marylebone Borough Council. The buildings have been erected in the enclosure known as South Villa, in which was located a handsome and unobtrusive residence with a garden of considerable size, and remarkable for the skill with which it was managed, as evidenced by the excellent fruit and other products that were exhibited from time to time at the meetings of the Royal Horticultural Society. As in the case of other of the central London parks, Regent's Park was originally Crown property, and a Royal mansion, with its grounds, existed on the site in Tudor times. Later the grounds were deparked, and in 1790 the mansion was taken down.

After numerous changes in ownership, Marylebone Park Farm, as the property was for a time called, reverted to the Crown in the time of the Regency. Nash then conceived a scheme for the utilisation of a certain area of land south of the farm, and this scheme was to culminate in a park of some 500 acres. Within the park was to be a Royal residence, and a number of villas adapted to the requirements of families of distinction. The residence for the Prince Regent, which was to have been built on the land now occupied by the gardens of the Royal Botanic Society, was abandoned, and some 400 acres of the area were gradually dedicated to public use. The scheme for the erection of private residences was proceeded with, but only some half-dozen were erected. These were provided with rather extensive grounds, and when the park was extended on the western side the lessees were given the exclusive use of broad belts of grass-land outside the grounds included in the lease. These belts were intended to prevent the public interfering with the enjoyment of the lessees of the grounds surrounding their residences, but they were granted on yearly tenancies only.

Some years since an area of about twelve acres of the land thus reserved was, after considerable controversy, thrown open to the public, and in consideration thereof 40 and 50 acres was secured to the tenants for the remainder of their leases. To the unobtrusive houses that have hitherto existed, from an æsthetic point of view exception could not well be taken; but to the obtrusive buildings that have been erected on the grounds of South Villa, and the land that has been reserved around them, there is the strongest possible objection. In any case, any reduction in the area of a park situated in such a densely-populated part of the metropolis as Regent's Park should not be permitted.

ANSWERS TO CORRESPONDENTS.

NATIONAL DAHLIA SOCIETY.—F. W., Oxford: I gather from a recent note in the GARDENERS' MAGAZINE that the National Dahlia Society has a new hon. secretary. I should be glad to learn his name and address. —The new hon. secretary of the National Dahlia Society is Mr. J. B. Riding, and his address is Forest Side, Chingford. We believe Mr. Riding takes over his new duties at once.

ROSES FOR THE ROCK GARDEN.—N. T. J., Saffron Walden: My rock garden is of modest dimensions, but I should like a few small-growing roses in it, and therefore ask you to kindly say which are the best kinds to plant.—Good and interesting roses for the rock garden are the pink and white moss variety, named De Meaux; Seraphine, a hybrid; the Scotch rose, R. pimpinellifolia; two gallica varieties, i.e., pumila and Burgandica; R. alpina pyrenaica, and R. nitida. Some of the dwarf polyantha roses would not be out of place in a rock garden.

PENTSTEMON HARTWEGI.—F. G. S., Skipton: Is Pentstemon gentianoides likely to prove hardy here? I have seen it growing well farther south, and believe it is quite perennial in warm districts. Kindly tell me whether it is best propagated from seeds or cuttings.—Pentstemon Hartwegi (or gentianoides) is one of the parents of the garden race of pentstemons. It is a fine garden plant, and is perennial in warm, well-drained situations. In the north, however, it is not likely to succeed as a perennial, and should be raised from autumn cuttings each year. The type grows rather above 2ft. high, and has long, tubular, deep red flowers. It is about seventy-five years since P. Hartwegi first flowered in English gardens. Propagation can be effected by sowing seeds in February in gentle heat. The seedlings must be gradually hardened off until by the end of May they are strong, and ready to be planted where they are to flower. Seedlings of P. Hartwegi show considerable variation.

GARDEN CROPS OF THE COMPOSITE ORDER.—C. E. F., Abingdon: Can you give me a list of the vegetable crops to be obtained from plants belonging to the order Compositeæ?—The chief vegetable crops obtained from this large and widespread natural order are artichokes, both Globe and Jerusalem, cardoon, lettuce, endive, chicory, salsafy, and scorzonera.

PROPAGATION OF YUCCA GLORIOSA. —S. T. A., Bath: Will you please tell me how the hardy yuccas, like Y. gloriosa, are propagated?—Where yuccas produce basal tufts these may be separated from the parent in spring or autumn. Some yuccas produce eyes or buds on the root-stocks. These fleshy buds should be detached during late spring or early summer, with a small portion of the root attached, and potted in small pots of rich soil. Placed in a closed cold frame, and carefully watered, growth and roots are soon developed, and the small plants are then duly hardened off ready for planting out. In other cases propagation can be effected by means of root cuttings placed in sandy soil and plunged in bottom heat. The latent eyes or buds soon develop under the influence of heat and moisture, and the individual plantlets can be dealt with as in the previous method.

MYRRH.—H. E. B., Worthing: Some discussion took place this recent Christmas time concerning Myrrh. Some of us believed it to be a fragrant Eastern plant, but we had no means of verifying our belief. Perhaps you will be kind enough to help us.—According to Smith's "History of Bible Plants," there are two distinct kinds of plants known as Myrrh, or rather, the word Myrrh is a wrong translation in some parts of the Bible. Where the translation is supposed to be wrong, the plant referred to is considered to be Cistus ladaniferus, popularly known as Gum Cistus, and yielding the fragrant gum called Ladanum. Where

BELL & BIEBERSTEDT'S

NOVELTIES of STERLING MERIT for 1913

New Pea—Warriston Wonder.

This splendid New Pea is from a cross between "The Bell" and "Gradus." Height five feet. A Main Crop with strong haulm and dark green foliage and pods borne in pairs, with ten to eleven immense Peas of exquisite flavour. We consider this the heaviest cropping Pea in cultivation, and can well recommend it for the Exhibition Table. We are sure it will become a great favourite with market gardeners. In sealed Packets (¼ pint each), **2/6** Retail. Stock limited.

New Pea—Bell's Premier.

This magnificent New Pea is a cross between "Gradus" and "The Bell." Height 5½ feet. A late second early with strong haulm and of medium green foliage, and pods borne in pairs, with nine to eleven large Peas of splendid flavour. It will become a grand Exhibition variety and can be well recommended for market growers. In sealed Packets (½ pint each), **2/6** Retail. Stock limited.

New Broad Beans—The Cropper.

This is a cross between "Aquadulce" and "Bunyard's Exhibition," and its robust habit and heavy cropping qualities are unrivalled for Exhibition purposes. The pods are well packed, containing eight to nine beans of most excellent flavour. Price on application.

Scotch Saved Seeds.

We can with every confidence recommend the under noted GENUINE SCOTCH SAVED SEEDS, having been very carefully rogued and selected by ourselves, and grown by First-class Growers in Mid and East Lothian.

When answering Advertisements please mention "Gardeners' Magazine."

the word "Myrrh" is a good translation, it has reference to some species of balsamodendron, one of which is named B. myrrha. A balsam exudes from the stems, or from cuts made in the branches, and this, when collected, forms the myrrh so frequently spoken of in the Scriptures as an article of commerce. Garden myrrh is a sweetly-smelling herb, named Myrrhis odorata.

ORNAMENTAL BEET.—S. E., Chislehurst: Please tell me which are the best kinds of beet to grow for ornamental purposes.—A good strain of Dell's, or any other dark-leaved variety, serves very well for ornamental purposes. Beta Cicla variegata is very handsome, and if raised in heat in February or March it will produce its shining, scarlet-ribbed leaves 3ft. long in good soil and a good summer. Dracæna-leaved beet has rather narrow purple leaves, and the Victoria beet has very showy metallic red leaves; both are useful in the flower garden.

NAMES OF PLANTS.

R. R., Everton.—1, Luculia gratissima; 2, Libonia floribunda; 3, Tillandsia usneoides.

C. H. R., Leamington.—1, Garrya elliptica; 2, Rhododendron racemosus; 3, Viburnum Tinus.

J. C. C., Essendine.—1, Abies concolor; 2, Primula floribunda; 3, Leonotus Leonurus; 4, Saintpaulia ionantha; 5, Oncidium cheirophorum.

T. D., Grantham.—1, Thuia occidentalis; 2, Cupressus macrocarpa lutea; 3, a form of Cupressus Lawsoniana; 4, Cupressus obtusa; 5, Cryptomeria japonica; 6, Ruscus racemosus.

OBITUARY.

MRS. THOMAS HUMPHREYS.

We very much regret to learn of the death of Mrs. Thos. Humphreys, wife of the Curator of the Birmingham Botanic Gardens. Mrs. Humphreys had recently to undergo an operation, and before recovering pneumonia supervened, and she passed away somewhat suddenly a few days before Christmas. Mrs. Humphreys was well known to those who regularly attended the daffodil and other exhibitions held in the Botanic Gardens, Edgbaston, because she was ever ready to extend those little hospitable kindnesses that mean so much to those who have travelled long distances and then have a number of exhibits to stage. We feel sure that all old Kewites, and all exhibitors at Edgbaston, as well as a large circle of friends, will join with us in sympathy to Mr. Humphreys in his great bereavement.

Portrait: Edward J. Russell, D.Sc., 1; Cattleya fabia, 3; Cotoneaster bullata, 5; Nuneham Park and Gardens: The Mansion, 7; View Across the Terrace Rose Garden, 8; The Nymphæa Garden, 9; A Beautiful Border of Roses, 10; The Dell, 11; Single Chrysanthemum Mrs. Loo Thompson, 13.

NEWS FROM HEADQUARTERS.

NON-CUSTOMERS ESPECIALLY INVITED.

Our Exhibition Warehouses at Raynes Park are thrown open just as freely to non-customers as to those whose names have been on our books for years. Our invitation is open to all. Every day is Visiting Day. There is no fee of any kind. No one is badgered to buy. Orders are not even mentioned.

Why not pay us a visit? You will be shown all over this great hive of industry. You will be taken into scientific research laboratories, where the wonderful Testing Instruments will be fully explained to you. You will see the most ingenious seed-cleansing, selecting, and packing machinery in the world. You will notice hundreds of packages of seeds ready for export to all parts of the world. You will see hundreds of happy operatives working under conditions of brightness, light, airiness, and hygiene that transform labour from its usual monotonous round to a pleasurable occupation. You will be shown where the staff take their meals and recreation. Your eye will be captivated by the vast trial grounds, in themselves a sight to see, especially during the months when the trials are in blossom. You will spend one of the happiest hours of your life. Bring your camera with you, and develop your snapshots in the excellently-fitted dark room where most of the illustrations for our catalogues are made.

Raynes Park is but a twenty minutes' motor run from Piccadilly, and about half-an-hour by rail from Waterloo. Or one may take the Underground to Wimbledon, and the tram from there—all trams stop by request outside the buildings.

Meantime, may we send along our new catalogue?

JAMES CARTER & CO.,

Seedsmen to His Majesty the King,

RAYNES PARK, LONDON, S.W.

The Reliable Family Medicine which has been used with unvarying success by Doctors and the Public for upwards of 60 years.

Dr. J. Collis Browne's Chlorodyne

Universally acknowledged to be the Best and Surest Remedy for

COUGHS, COLDS, ASTHMA and BRONCHITIS.

Is the only palliative in NEURALGIA, TOOTHACHE, GOUT, RHEUMATISM.

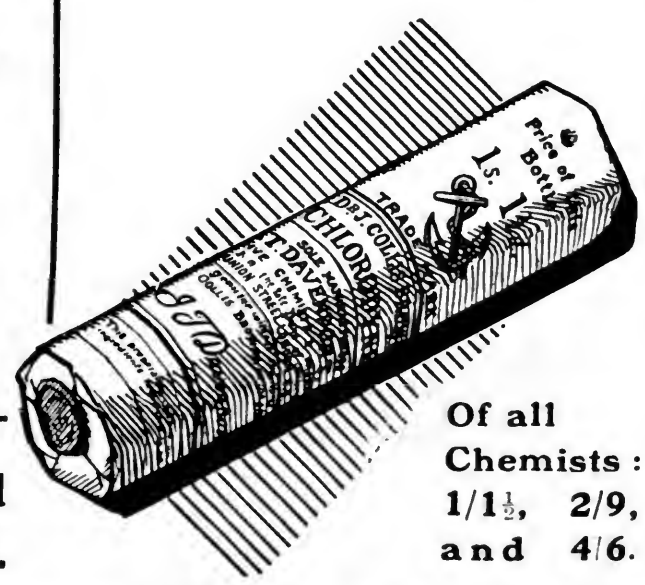
It effectually cuts short all attacks of SPASMS, HYSTERIA, and PALPITATION.

In DIARRHŒA, CHOLERA and DYSENTERY it acts like a charm.

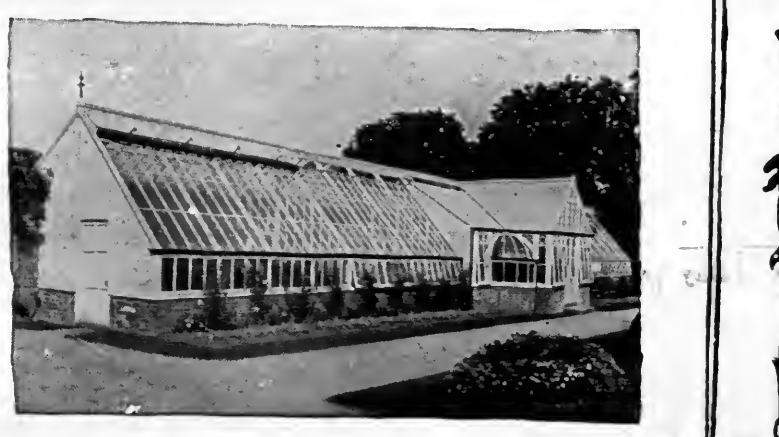
Always ask for and see that you get the ORIGINAL and ONLY GENUINE Chlorodyne—Dr. COLLIS BROWNE'S.

The secret of the manufacture of Dr. J. Collis Browne's Chlorodyne has never been divulged, and compounds called Chlorodyne cannot possess the same curative virtues. Purchasers should therefore see that the name is on the stamp, and refuse substitutes.

Convincing Medical Testimony accompanies each Bottle.



Of all Chemists: 1/1½, 2/9, and 4/6.



MODERN GLASSHOUSES

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

LOUGHBOROUGH LEICESTERSHIRE
London Office 122 VICTORIA ST S.W.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

HARDY AZALEAS.

Borders on both sides of carriage drives and entrance paths, also beds and shrubberies in the flower garden, may be greatly improved by the addition of a judicious selection of hardy azaleas. As it takes many years for these plants to grow to a large size, that is, 4ft. or 5ft. through, the cultivator should not have much difficulty in disposing the specimens for general effect at the time of planting.

When they are to be associated with other kinds of shrubs, care should be taken to avoid having the azaleas hidden by the more rapid growth of the others. In broad shrubberies it will be necessary to plant the majority in the front part, but if a few standards are put in near the back portion the masses of colour which these plants produce will be more evenly disposed.

There are many lovers of hardy azaleas who do not make the attempt to grow them in the open borders unless the soil is of a peaty nature. But it is a mistake to refrain from growing them on this account as they will thrive well in a good deep loam, and also in one mixed with gravel and sand.

In the New Forest, in Hampshire, there is a large garden in which azaleas do remarkably well, but the plants are not growing in a peaty soil. A small quantity of peat is used, but only to assist in establishing the plants; the original soil is a mixture of sand, gravel, and clayey loam.

Some of the specimens in the borders on both sides of the long carriage drive are now splendid ones, and flower very freely indeed. They retain their leaves well, and keep very free from red spider and thrip. Many cultivators of these plants would be very proud to have them as fine in pots as they are in some outside borders.

Standards look best when grown singly and at least 12ft. apart, but the dwarf plants should be grown in groups either mixed or of one colour in each group, with single specimens between at intervals of 60ft. or so, where long borders are concerned.

The soil must be pressed down rather firmly around the roots, and left cup-shaped on the surface immediately around the stems (especially where the border has a sloping surface) to retain rain and other water, as every precaution should be taken against the possibility of the soil getting dust-dry at any time. G. B.

Saintpaulia ionantha.—Noteworthy features of this little gesnerad are its extreme floriferousness, the rich purple-blue of its blossoms, and the fact that they are produced at practically all seasons, but especially in the early months of the year. Last season an undergrowth of this saintpaulia, overtopped by fine examples of Euphorbia fulgens from the gardens at Hatfield, was greatly admired at one of the meetings of the Royal Horticultural Society.—K.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Carbonic Acid Gas.

Amongst the three gases which compose the air we breathe and the universal envelope of the earth's surface, viz., oxygen, nitrogen, and carbonic acid, the last-named stands alone as a compound, the other two being quite simple elements, gases pure and simple. Carbonic acid, on the other hand, though equally tenuous and invisible, consists of a mixture of that very solid substance, carbon, and one of the other two gases, viz., oxygen, so that really as gases proper there are, after all, only two, and not three, in the atmosphere, save very minute quantities of others which may be regarded as accidentally present. If we obtain a volume of carbonic acid in a closed vessel, as we can do by mixing a Seidlitz powder in a large glass, we shall see nothing above the liquid, but the presence of the gas is unmistakably indicated if we plunge a lighted match into the glass, since it will be as immediately and thoroughly extinguished as if we plunged it into the watery solution lower down; the presence of the gas excluding the free oxygen which is essential to combustion, while its greater weight prevents it from immediately escaping. Carbonic acid gas in this form is quite inert, and hence, though in taking the powder in question, we inhale some, and swallow some as well, it will do us no harm, its suffocating character being solely due to the exclusion of oxygen from the lungs when it is inspired in large quantities. The actively toxic form of carbonic acid gas is of a different composition, with which it is not our object to deal. The proportion of carbonic acid proper in our atmosphere is very small—about one part in three thousand—and yet, as we shall presently see, it is of equal vital importance to our existence, as is the free oxygen which forms so much larger a proportion of the air we breathe, and without which we should all expire as suddenly as the match flame in the glass we have cited. We arrive at a comprehension of this fact when we consider, firstly, that all plant life is dependent upon this carbonic acid gas in the air for its existence, and, secondly, that all animal life is dependent upon plant life, directly or indirectly, for its nourishment and support. Eliminate that comparatively minute proportion from the air, all plants would perish, and it would be only a question of a very brief time devoted to the consumption of any accumulated stores of plant food, before all animal life would perish by starvation. All plants, too, in the process of growth, absorb the carbonic acid through their leaf pores, and by decomposing it and utilising the solid carbon for their innumerable products, nutritive and other, set the oxygen free, and thus, to a certain extent, replace that which is consumed by the animal world, one of whose functions it is to recombine such oxygen with the carbon carried by the blood to the lungs, and exhaled with every expired breath. From this we see that the plant world and the animal world play, to a certain extent, reciprocal rôles in maintaining the natural balance of the aerial gases. When, however, we take a comprehensive purview of the life of both kinds existent on the earth's surface, and bear in mind that, as our geological research proves, enormous quantities of the solid carbon derived from the air by plant life has been practically locked up, and, presumably, is still being locked up, in the shape of coal, peat, and analogous deposits, and when, furthermore, we take into account the millions on millions of square miles of land densely covered with practically permanent forests, we find ourselves confronted with a great puzzle. In the first place, compared with all this continuous growth and formation of timber over such vast areas, the animal world presents absolutely no equivalent as a carbonic acid restoring agency, and in the second, every ancient or so-called primeval forest stands upon an immense accumulation of locked-up carbon, and, year after year, age on age, and probably æon on æon, it is adding to this store, and yet the aerial supply seems inexhaustible, and no data exists indicating a diminution. The volume of the atmosphere is enormous, but calculations show that, given the area of a forest, the carbonic acid over such area would be exhausted in a few years to form the solid wood below, and hence the ultimate exhaustion of the supply would appear to be determinable by a simple calculation of areas generally which could not result in a period of very long duration; certainly not such stupendous periods as geology deals with. It may be argued that in these days of coal mines, we are restoring in the air some of the locked-up carbon of those days, but no thinking man would argue that this forms an appreciable contribution to present vegetative activity, nor, comparing the ubiquitous character of vegetable life, as compared with the sporadic character of animal life, is it easy to conceive that the contribution of the latter to the existence of the former by carbonic acid emission is anything but trifling. The problem is indeed a difficult one to solve.

MR. J. BETHEL.

Mr. James Bethel, whose portrait we give in this issue, is the popular president of the Broughty Ferry Horticultural Association, and is head gardener at The Grange, Monifieth. He fills both positions with such ability that there would be some difficulty in determining in which he excels. He has certainly proved to demonstration that he is fully conversant with all that relates to the garden and its management, for in The Grange gardens evidence is forthcoming on all sides of cultural skill of the highest class, and of a full appreciation of neatness and order. Further evidence of his cultural abilities is found

in the numerous prizes that have been gained for plants, flowers, fruits, and vegetables. Since taking charge of The Grange gardens Mr. Bethel has given a considerable share of attention to the work of remodelling them, and has effected many improvements in the several departments. No name is more familiar among the horticulturists in the north-east of Scotland than that of Mr. Bethel, yet many are not aware that he is a native of Ireland, where he had his early training. Coming to Scotland about twenty-five years ago, Mr. Bethel made Dundee the centre of his activities, and except for one year, when he returned to his native country for a short stay, he has been located not more than twenty miles from the city of his adoption. His geniality and high sense of justice have made him popular as a judge, and his readiness to give advice on the practical work of the garden has obtained for him the esteem of large numbers of amateurs. If Mr. Bethel has hobbies they are hardy fruits, herbaceous plants, and British ferns, for, judging by results, he would appear to be especially interested in all three. While taking an active part in the work of the association of which he is president, he is frequently to be met with at the meetings of kindred bodies, and invariably has the warmest of welcomes.

The Temperature of December.—In a letter contributed to "The Times" of the 3rd inst., Dr. H. R. Mill gives some interesting particulars of the abnormally high temperature experienced during last month. In the table that accompanies his letter he shows the average temperature of each month for the fifty years 1860-1909, and the mean temperature of each month in 1912, together with the difference from the average. It is seen that December, 1912, with a mean temperature of 45.8 deg. was no less than 6.1 deg. warmer than the long average; and Dr. Mill states that there is only one previous December on record, that of 1868, which had a higher temperature, and that was only 46.0 deg., one-fifth of a degree higher than in 1912. The temperature of the very warm December, 1911, was 44.7 deg., or 1.1 deg. lower than last month. The mean of the highest temperature of each day in December, 1912, is shown to have been 50.8 deg., which is higher than has ever been recorded before. The nearest approach was in 1868, with 50.7 deg., and in 1900, with 50.1 deg. These are the only instances in which the mean maximum shade temperature has exceeded 50 deg. for December. Dr. Mill points out that the extremely cold months of August, September, and October put a stop to a run of fifteen consecutive months all above the average, and reduced the mean temperature for the year 1912 to 50.9 deg., which is only 0.9 deg. above the average.

St. Petersburg International Exhibition.—A short time since a conference on International exhibitions was held at the Palace of the Reichstag, Berlin, with M. Chapstal as president. As the result it was resolved that the regulations relating to the participation of the various Governments in such exhibitions should be as follows: (1) Not more than one International exhibition shall be officially organised in the same country in any ten years; (2) that in the several countries in whch an adherence is given to the regulations there shall be only one exhibition in three years, and that the duration of the exhibitions shall not in any case exceed six months. A resolution was also passed in favour of guaranteeing the exhibitors against the various risks to which their exhibits are exposed. In consequence of the regulations made by the conference the International exhibition at St. Petersburg, which was arranged to be held in April next, about the same time as that at Ghent, has been postponed until 1914.

The Gardeners' Magazine Index.—The index to the volume of the GARDENERS' MAGAZINE for 1912 will be published next week, and may be obtained, post free, price 2½d., from the Publishers, 148 and 149, Aldersgate Street, London, E.C. Handsome cloth covers for binding a year's numbers are also obtainable, price 2s. 6d., post free.

Bright Sunshine in 1912.—The following is the mean duration per day of bright sunshine in the past twelve months at Kew, with the difference from the average: January, 0.7 hours, —0.7 hours; February, 1.3,—0.5; April, 7.8,+2.9; May, 5.5, —1.0; June, 6.4, —0.2; July, 4.9, —1.9; August, 3.5, —2.6; September, 3.7, —1.0; October, 3.7, + 0.6; November, 1.0, —0.7; December, 0.9, —0.3. The mean duration per day for the whole year was 3.5, —0.5. It will be understood that the figures relate to hours throughout.

Prizes for Books on Gardening.—The National Horticultural Society of France does not limit its activities to the encouragement of the exhibitors at its shows, but makes awards to those who distinguish themselves as writers on gardening matters, and also to those who afford evidence of merit by long service. Consequently, at the distribution of prizes at the society's last meeting for 1912 a number of medals were awarded to authors. These awards included a gold medal to M. O. Opoix for the third edition of his "Culture of Pears"; silver-gilt medals to M. Lemee for "The Enemies of Plants," and M. André Véra for "The New Garden"; a diploma for large silver medal to M. L. Lesourd for "Culture of Osiers"; silver medal to M. R. de Notre for "The Osier and its Culture"; and to M. A. Van den Heede for "Early Fruits and Vegetables"; and a diploma for silver medal to M. Th. Durand for "The Manual of Practical Fruit Culture." A gold medal was awarded to M. A. Trifforiot, head gardener at the Chateau of Chaumont-sur-Loire, for long and good service.

Influence of Light on Vegetation.—In his recent lecture on "Light," at the Royal Institution, Sir James Dewar dwelt somewhat fully on the influence of sunlight on vegetation. In his opening remarks he stated that Priestley, in the course of his investigations, discovered that contaminated air placed over a vessel of water in which a green plant, the algæ, was growing, became purified; and he traced the purification to the green plant, which absorbed the carbonic acid, and, in turn, yielded oxygen. Thus was established the relationship of mutual helpfulness between plants and animals. The amount of this leaf-green—or the ordinary colouring matter of vegetables, which was so essential to man's existence—on the earth's surface was incalculable. To count the number of leaves on a plant or to measure them would be tedious, but if it were done the immense area of the leaves, as compared with the small space occupied in the ground by the plant, would cause some surprise. By a brief immersion of a leaf in spirits of wine it was shown that it was deprived of its green colouring matter, and how a transmitted light brought to bear on the solution turned it into a deep green. By such experiments it was discovered that light entered the plant through this green colouring matter, and was utilised by the plant in building up its woody structure. Ingenhouss was the first investigator who, in the eighteenth century, showed that the absorption of carbonic acid by the plant was dependent on the influence of the light of the sun, and not of its heat. A century later Boussingault proved that leaves decomposed carbonic acid immediately on exposure to sunlight, and ceased their action instantly in darkness, and he also found that nine square feet of leaf surface, acting during twelve hours of the day, decomposed 306 cubic inches of carbonic acid, yielding nearly the same volume of oxygen.

Market Gardeners and Compensation.—The text has been issued of a Bill introduced into the House of Commons by Mr. W. Runciman, President of the Board of Agriculture, to remove doubts as to the effect of Sub-section (2) of Section 42 of the Agricultural Holdings Act, 1908, and the enactments re-enacted in that sub-section. It is now declared that a tenancy from year to year under a contract of tenancy current on January 1, 1896, shall not be deemed to have been determined thereafter by any provision in Section 61 of the Agricultural Holdings (England) Act, 1883, and part of the sub-section is to be repealed. That Act shall apply to any claims for compensation which has not before the passing of the present measure been determined by any judgment or order of a court of competent jurisdiction or award or agreement, whether the improvement to which the claim relates was made or begun before or after the commencement of the Agricultural Holdings Act, 1908.

Popular Sweet Peas.—The audit of varieties shown at the exhibition of the National Sweet Pea Society forms, as usual, an interesting feature of the "Sweet Pea Annual." From this we learn that there were the same number of exhibits in 1912 as in 1911, but there were 351 more bunches staged, the total being 2,257, and 80 more varieties! The number of bunches has only been exceeded twice, i.e., in 1907 and 1909, while the number of names is far and away the largest found at any show the society has held. The percentage of bunches per variety is the lowest ever recorded; it was 7.62, as compared with 8.99 in 1911; 7.755 in 1910; 13.33 in 1909; 9.60 in 1908; 11.65 in 1907; 12.82 in 1906; 15.34 in 1905; 14.58 in 1904; and 11.01 in 1903. Sixty-two varieties were shown 10 or more times; 5 varieties 9 times; 4 varieties 8 times; 7 varieties 7 times; 4 varieties 6 times; 12 varieties 5 times; 11 varieties 4 times; 14 varieties 3 times; and 29 varieties twice each; while 144 varieties were represented once only. Clara Curtis reached the premier position, after being second in 1911, fourth in 1910, and eighth in 1909. Thomas Stevenson has come with a rush, as it is second, and was only thirty-second on the list in 1911. Elsie Herbert keeps third position, and Etta Dyke goes down to fourth place. Mrs. C. W. Breadmore, fifth in 1911, was equal fifth with Maud Holmes in 1912, the latter variety being fifteenth in the former year. John Ingman occupies about the same relative position as in 1911. Mrs. Hugh Dickson has dropped back a good bit, while 45 bunches of Mrs. W. J. Unwin were staged in 1912, as against 17 in 1911. Sunproof Crimson is one place better with an increase of three bunches over 1911. Nubian, Edrom Beauty, Hercules, Elfrida Pearson, Doris Usher, Barbara, R. F. Felton, and Melba have come well to the front, but Mrs. Hardcastle Sykes, Tennant Spencer, Helen Lewis, Constance Oliver, and Flora Norton Spencer have all been represented by fewer bunches than in 1911, while

Countess Spencer has fallen from 53 to 19 bunches. Both Etta Dyke and Clara Curtis were shown 80 and 78 times in 1911, whereas Clara Curtis, at the top, was shown 73 times in 1912.

New Prize for Roses.—With a view to complete the International classes for new roses from Bagatelle at the exhibition of the National Horticultural Society, to be held at Paris in May next, M. Gravereaux has presented to the society a silver cup of the value of £20. The cup will be offered for the most beautiful rose exhibited at the society's exhibition in May, either in pots or as cut blooms. Varieties distributed in the year previous will not be eligible for competing for the cup.

The Grounds of La Muette.—The fears of the lovers of Paris for the fate of the Park of La Muette, a portion of which has been sold by Comte de Franqueville, have, according to the Paris correspondent of "The Times," been set at rest by the announcement that the character of the beautiful alley of lime trees in the grounds will not be affected. Nearly half the land sold has already been bought from the purchaser, M. Bloch Levalois, by M. Henri de Rothschild, who intends to build a gallery in a secluded portion of the park to house his art collections. The remaining piece of land will fall into the hands of the builders, but with the obligation upon them to respect the trees and to erect only the best class of large private residence. The chateau and grounds of La Muette are situated in Passy, and are within the fortifications and the barrier of the Paris Octroi. The part of the Bois de Boulogne which adjoins these grounds is the region most frequented by children and nursemaids, and may be described as the Kensington Gardens of Paris. There is, of course, no statue of Peter Pan, but there is a well-known statue of La Fontaine with representations of various animals, the crow, the fox, and the mouse, from his fables.

Germination of Dodder Seeds.—Some trials that were made for the purpose of testing the germinating capacity of the seeds of several species of dodder have given interesting results. Seeds of Cuscuta suaveolens were found to have a higher germinating capacity than those of C. trifoli, which is generally known as the Common Dodder. At the end of twenty-eight months 67.6 per cent. of the first-named germinated, as compared with 47 per cent. of the latter. The seeds of both species are slow in germinating, but the largest percentage germinates in the month following that in which the sowing is made. The germination then proceeds during the following months in diminishing numbers. It was found that 6 per cent. of the seeds of C. trifoli which had not germinated after twenty-seven months, and that 12 per cent. of the seeds of C. suaveolens which had not germinated after twenty-eight months, were alive. Thus dodder seeds once sown with a crop are a constant source of danger.

Report on the Paris Conference on Genetics.—We are informed that the full report of the Congress on Genetics, which was held at Paris last autumn, is on the point of being published. It forms a substantial volume, and is freely illustrated in black and white, and contains also several coloured plates. It will contain, in addition to the text of the papers that were read, a resume in French of the English papers, and a resume of the English papers in French. The price of the report will be 25 francs (= £1).

EARLY-FLOWERING ADONIS.

Among the most effective of spring-flowering subjects that are alike suitable for the bolder type of rock garden, or the foreground of borders or shrubberies, the species and varieties of adonis merit attention. Not only are they reliable and easy to grow, but they are brilliant in the extreme, and once suitably planted they call for little or no after attention. The condition under which they most generally succeed is in a rich moist loam, and in positions fully open to the sun, or with moderate shade. The best known kind is Adonis vernalis, a European species, whose golden-yellow flowers appear in March, surmounting the mounds of delicately-cut leafage, the latter presenting an effective foil to the burnished gold of the flowers.

Adonis amurensis is an Asiatic species, also early flowering. It attains a height of twelve inches, having the typical fennel-like foliage of the last-named, and large golden-yellow flowers some two inches across. Of this species there is a double-flowered form that is quaintly beautiful, and equally desirable as a garden plant.

Adonis pyrenaica closely resembles vernalis, but with broader petals, and it blooms some six to eight weeks later. The flowers are deep yellow, carried on branching stems some fifteen to eighteen inches in height.

All the species of perennial adonis are propagated by division or seed. The latter should be sown as soon as ripe, in protected positions, out of doors, or in boxes of sandy soil placed in hand frames. Propagation by division can only be carried out at rare intervals, as the plants resent frequent disturbance at the root.

THOMAS SMITH.

Coombe Court Gardens.

ODONTONIA FIRMINI.

Flowers white with yellow crest and pink flushed lip. A.M., R.H.S., January 7. M. Firmin Lambeau, Brussels. (See page 34.)

HOW ALTITUDE AFFECTS PLANTS.

(Continued from page 13.)

The lovely columbine, Dyer's weed (fond of chalky soils), musk mallow (a sand lover), meadow crane's bill (an alluvium plant), alder buckthorn, scabious, corn marigold (ranging higher sometimes), great bindweed, gipsywort, birch, black and white willow, and the osier grow up to an altitude of 400 feet. Here also grow yellow flag, snowdrop, black briony (a pretty creeper), and water plantain (a graceful aquatic). Some gentians and fly orchid grow anywhere between 100 and 400 feet.

Rock rose (common on the chalk downs), spindle tree, dewberry, agrimony, London pride, sanicle, flea bane, have their limit generally at 500 feet; and tansy, privet, centaury, mullein (a favourite in old gardens), musk, and hop, green-winged orchid, frog orchid, and melic grass are found up to this altitude. Watercress (largely cultivated in tanks), Jack-by-the-hedge (another salad), St. John's Wort, trailing rose, guelder rose (both suited to the shrubbery); felwort, a gentian; Creeping toadflax, an ornament for walls and rock beds; Skull-cap, hemp nettle, the beech, a handsome tree, fond of the chalk; fragrant orchid, and the common pondweed may be grown up to 600 feet.

It is possible to cultivate a hundred feet higher dog violet, valerian, ragwort, sheep's bit, scabious, bog myrtle (a fragrant undershrub), and creeping willow. The sycamore, wild cherry, carline thistle, hound's tongue, bittersweet, eye-bright, yew, and millet grass will flourish up to 800 feet. Ragged robin (forming handsome pink patches), gorse, broom, bird's-foot trefoil, great burnet, crab, stonecrop, Cicely (fond of limestone), elder, ox-eye daisy, hare-bell, red rattle, wood sage, aspen, and lily of the valley may grow on hills rising to 900 feet.

The 1,000 feet contour marks generally the upper limit of enchanter's nightshade, field scabious, sneezewort, bogbean, and the oak. At 50 feet higher may grow wild anemone, bird cherry, angelica, hogweed, woodruff (with scent of new-mown hay), the ash, alder, smooth-leaved elm, and herb Paris.

At 1,100 feet it is possible to grow kingcup, sloe, raspberry, hawthorn, honeysuckle, dog's mercury, silver birch, hazel, goat willow, and other coppice trees, as well as spotted orchid and others.

When we reach an altitude of 1,200 feet, or considerably higher than any hills in the plains of Central or Southern England, we find such plants flourish at this altitude as goldielocks, dog roses, rosebay (a handsome plant of which there is a garden form), ivy, willows, ramsoms, and the bluebell cuckoo pint, a plant which is very chary of growing on certain soils.

At an altitude of 1,400 feet, the great stitchwort (a lovely pearly-white flower), herb Robert (which scents the roadside), holly (which forms great thickets, used for pheasant coverts), meadow sweet, wild strawberry (with its luscious fruits), scabious, coltsfoot, and the foxglove (stately and tall, a favourite in the garden) are all at home. Here, too, in bogs, grow butterwort (now rare), the juniper, and the Scotch pine (which lends such picturesqueness to the landscape, grown in clumps on rocky knolls).

At still a hundred feet higher milkwort, mountain ash, sundew (the interesting bog plant with insectivorous habits), golden rod, cow-wheat, and willows, will grow with luxuriance. Wood rush grows at 1,600 feet in some places

Whortleberry, cross-leaved heath, bog asphodel, and field spike-rush will flourish at 1,800 feet.

Lesser spearwort, bog violet, milfoil, sorrel, cowberry, and many others may be found at an altitude of 2,000 feet. At 50 feet above this grow wood sorrel, daisy, whortleberry, ling, thyme, the nettle (which prepares the ground for other plants), cotton grass, and mat grass, the last forming associations by themselves, whilst ling also grows with whortleberry in the same gregarious manner.

It is needless to point out that such altitudes as we have given are only averages or limits at which the plants mentioned may grow. At different places the usual altitude varies, according to some other factor which may influence the normal orography of the district, such as absence of woodland from artificial causes, lack of water, perpetual snow, or a multitude of other inter-related factors.

The absence of such facts in the ordinary handbooks on gardening or horticulture is due to the fact that ecology, of which they form a part, is as yet a new science. But it is beginning to be more apparent every day that the gardener can no longer afford to be behindhand in his knowledge of the essential laws that govern plant life, and of which ecology is an important part, otherwise he will find someone else is before him, and with better results, which in these days of competition and progress will be to his disadvantage. The few hints here given will serve as a beginning.

A. R. HORWOOD.

Leicester Museum.

PREPARATION OF LAND FOR FRUITS.

When a site has been decided upon for an orchard or fruit plantation the first thing to do is to prepare it to receive the trees, since scarcely any land, except that which has been cultivated intensively, is fit for planting without some preparation.

The first thing to do is to make sure that the drainage is good, and, if not, to remedy any defect in this matter. It is quite useless to expect really good results from fruit trees planted in water-logged soil.

If the planter has been cultivating the land for some time previously he will know exactly whether any draining needs to be done, but if he has but recently come into occupation of the holding, it may be necessary for him to sink a few trial holes a couple of spits deep on the site to see if they fill with water from the subsoil, and also if any rain water that may accumulate fails to get away rapidly, and if either should happen to be the case, draining must be taken in hand.

In carrying out a system of drainage it should be borne in mind that the work must be thoroughly done. As a general rule no partial measures or "patching" is of much use.

Where there are old drains running in one direction it will be as well to take the new drains across them somewhat so as to intersect them, and thus draw any water that may collect in them. There is no more fruitful cause of water-logged soil than old drains which are blocked at the outlets, as they collect the water without being able to convey it away. It is wise to arrange all the drains, if possible, with one leader, so as to have only one outlet into the open ditch or stream. This outlet is not likely to be overlooked and forgotten, as one of a number may be; further, it has a very much greater "head" of water behind it to carry away any obstruction, leaves, etc., from the mouth, which might be liable to block it.

When the draining has been finished the land, if of sufficient area, should be ploughed, but if not large enough for ploughing it should be dug.

The ploughing should be as deep as possible, using either three or four horses, but not so deeply as to bring up the subsoil to the top, but the latter should be thoroughly broken up by a subsoil plough following in the furrow. Land which is to be dug should be bastard trenched, the subsoil being thorough broken up during the course of the operation.

Whether the land be ploughed or dug, it is not advisable to apply stable manure at the time. If the land is in need of a dressing of manure to supply the necessary organic matter, it is much better to defer the planting for a season, and give a heavy dressing of manure, and take a crop of potatoes or roots. These crops will serve to break down the soil, and afford an excellent opportunity for finally cleaning the land. Moreover, the manure will be thoroughly decomposed, and what is not taken up by the crop will be in a form available for the trees.

While it is not possible to get rid of every weed, fruit trees should not be planted until such perennials as couch grass, bindweeds, docks, thistles, and coltsfoot are exterminated. The two first-named are the most troublesome, and when once they find they way to the tree roots it is almost impossible to dislodge them without first uprooting the tree.

After the land is ploughed or dug it should need nothing further in the way of cultivation prior to planting, but the planter must be careful not to attempt to start until the surface soil is dry enough to admit of the planting being done without spoiling the mechanical condition. It is far better to lay the trees in by their "heels" and wait till the drying winds of February or early March have passed over the land than to puddle the surface soil in an attempt to carry out the planting now. When trees are to be planted in grass that is not to be disturbed very little can be done in the way of preparation, but there are one or two points which must be attended to. In the first place, it is absolutely necessary the subsoil should be well drained to the depth of about thirty inches. In planting on grass the soil is, of course, only broken up at the stations where the trees will stand, and if the subsoil be of at all a retentive nature these holes become basins, to which the water collects, and makes the soil sour. The remedy lies in either running the land drains up the lines on which the trees will stand, or mole-draining up the same lines; or planting on a mound of soil brought on to the land for the purpose, so as to avoid disturbing the subsoil at all.

Whatever method be adopted, the soil for at least a foot beyond the spread of the roots, all the way round, must be kept free of grass, and this cultivated circle must be annually extended as the roots travel away from the stem of the tree.

F. W. HAMMOND.

Pinguicula caudata.—In an intermediate orchid house this Mexican Butterwort is almost continuous flowering, but at no time are its pretty carmine-pink blossoms more appreciated than they are in the depth of winter. There is a comparatively new species—P. Rosei, whose flowers are, except in their violet colour, a counterpart of the above. Between these two hybrids have been raised at Kew which are in the colour of their blossoms about midway between their parents.—S. W.

BEAUTIFUL ROSE HEDGES.

It is very pleasant, on returning to England, after a long dusty journey through the flat, hedgeless country which lies between Paris and Calais, to find oneself once more looking on the green of English meadows and hedgerows. If this return should be in the "leafy month of June" the grass will be its greenest, and the hedges will be sweet with the blossoms of the wild rose, for Rosa canina, the typical English wild rose, never seems so happy as when throwing up its great arching sprays from the midst of a hedgerow.

This being so, is it not curious that it our English gardens we do not make more use of roses for hedges, or that we more often find pergolas than hedges of roses?

Now, England is the home of hedges, whereas Italy is the home of the pergola. The word itself is Italian, and means a trellis for vines, and it would seem to be a construction well suited to a sunny climate, where vines may grow and ripen their fruit in the open air, to the eminent satisfaction of the passenger under the pergola, who may enjoy the shade of the big vine leaves, and, possibly, also test the flavour of the grapes, as he takes his walks in his formal garden. There are, of course, many gardens in England where a well-made pergola is not out of place, but even then it may be questioned whether it is best planted with roses only. The ornamental vines and the clematis, and plants which climb and cling more naturally than any roses do, are in some ways more suitable for clothing a pergola.

But it is not my wish to bring an indictment against rose pergolas, which can be very charming if well built and rightly placed. I would only suggest that in our English climate we far more often want shelter from wind than from sun, and that a green roof may too often be a dripping one, while a screen to break the north or east wind is almost always grateful, both to ourselves and to any plants we may wish to shield.

It is, however, not only in gardens that rose hedges are somewhat neglected, but also in rose books. I have looked through a great many, and find that though most will give instructions for "Roses for Pergolas and Pillars"—how to train and prune them, etc.—very few say much on the subject of rose hedges. If hedges in connection with a rose garden are mentioned, it is generally suggested that a yew hedge is the most suitable. No doubt a yew hedge makes a splendid background for the flowers, and if the rose garden is on formal lines, and is quite shut off from the main garden, nothing looks better or gives a better shelter. Yew and box are much used for hedges in Italian gardens, where their dark shades of green are very pleasant.

But there are many gardens in which the formality of a yew hedge is quite out of keeping; or where the owners of the garden wish to obtain as much floral effect as possible, and do not care for the evergreen or "idly green" yew. In such gardens it may be the roses are not grown apart from all else, but have nevertheless so taken possession of the place that their beauty appears in every direction. Here rose hedges and screens will be very welcome. In his book, "The Rose Garden," Mr. William Paul suggests that if a screen between two parts of the rosarium is required, nothing is more fitting for the purpose than the sweet briar, "which," he writes, "should abound in every rosarium, for the delicious fragrance of its young leaves in spring, the delicacy of its blossoms in summer, and the gay appearance of the scarlet heps in autumn must recommend it to every observer." Since this was written Lord Penzance's hybrid sweet briars have been introduced, and I know, from the effect in our own garden, what a delightful hedge they make.

ROSE QUEEN OF THE MUSKS.

A charming variety with blush-coloured flowers, raised by Messrs. Paul and Son, Cheshunt, and awarded the silver medal of the National Rose Society, September 12, 1912. (See page 26.)

We have them planted at the back of an herbaceous border. They were originally trained up some four-feet iron railings, but as the hedge grew taller some strands of galvanized wire were stretched through iron uprights inserted between the railings. The plants are now about twelve feet high, and they make an efficient and most sweet screen. We planted several varieties, but find that Meg Merrilees, Amy Robsart, Anne of Gierstein, and Jeanie Deans have proved the strongest. They throw up immense rods from the bottom every summer. These must be carefully laid in, and some of the old wood cut out as soon after flowering as possible. No other pruning is required. If this is attended to every year the screen will be covered with blossoms, and the plants will not become thin and leggy.

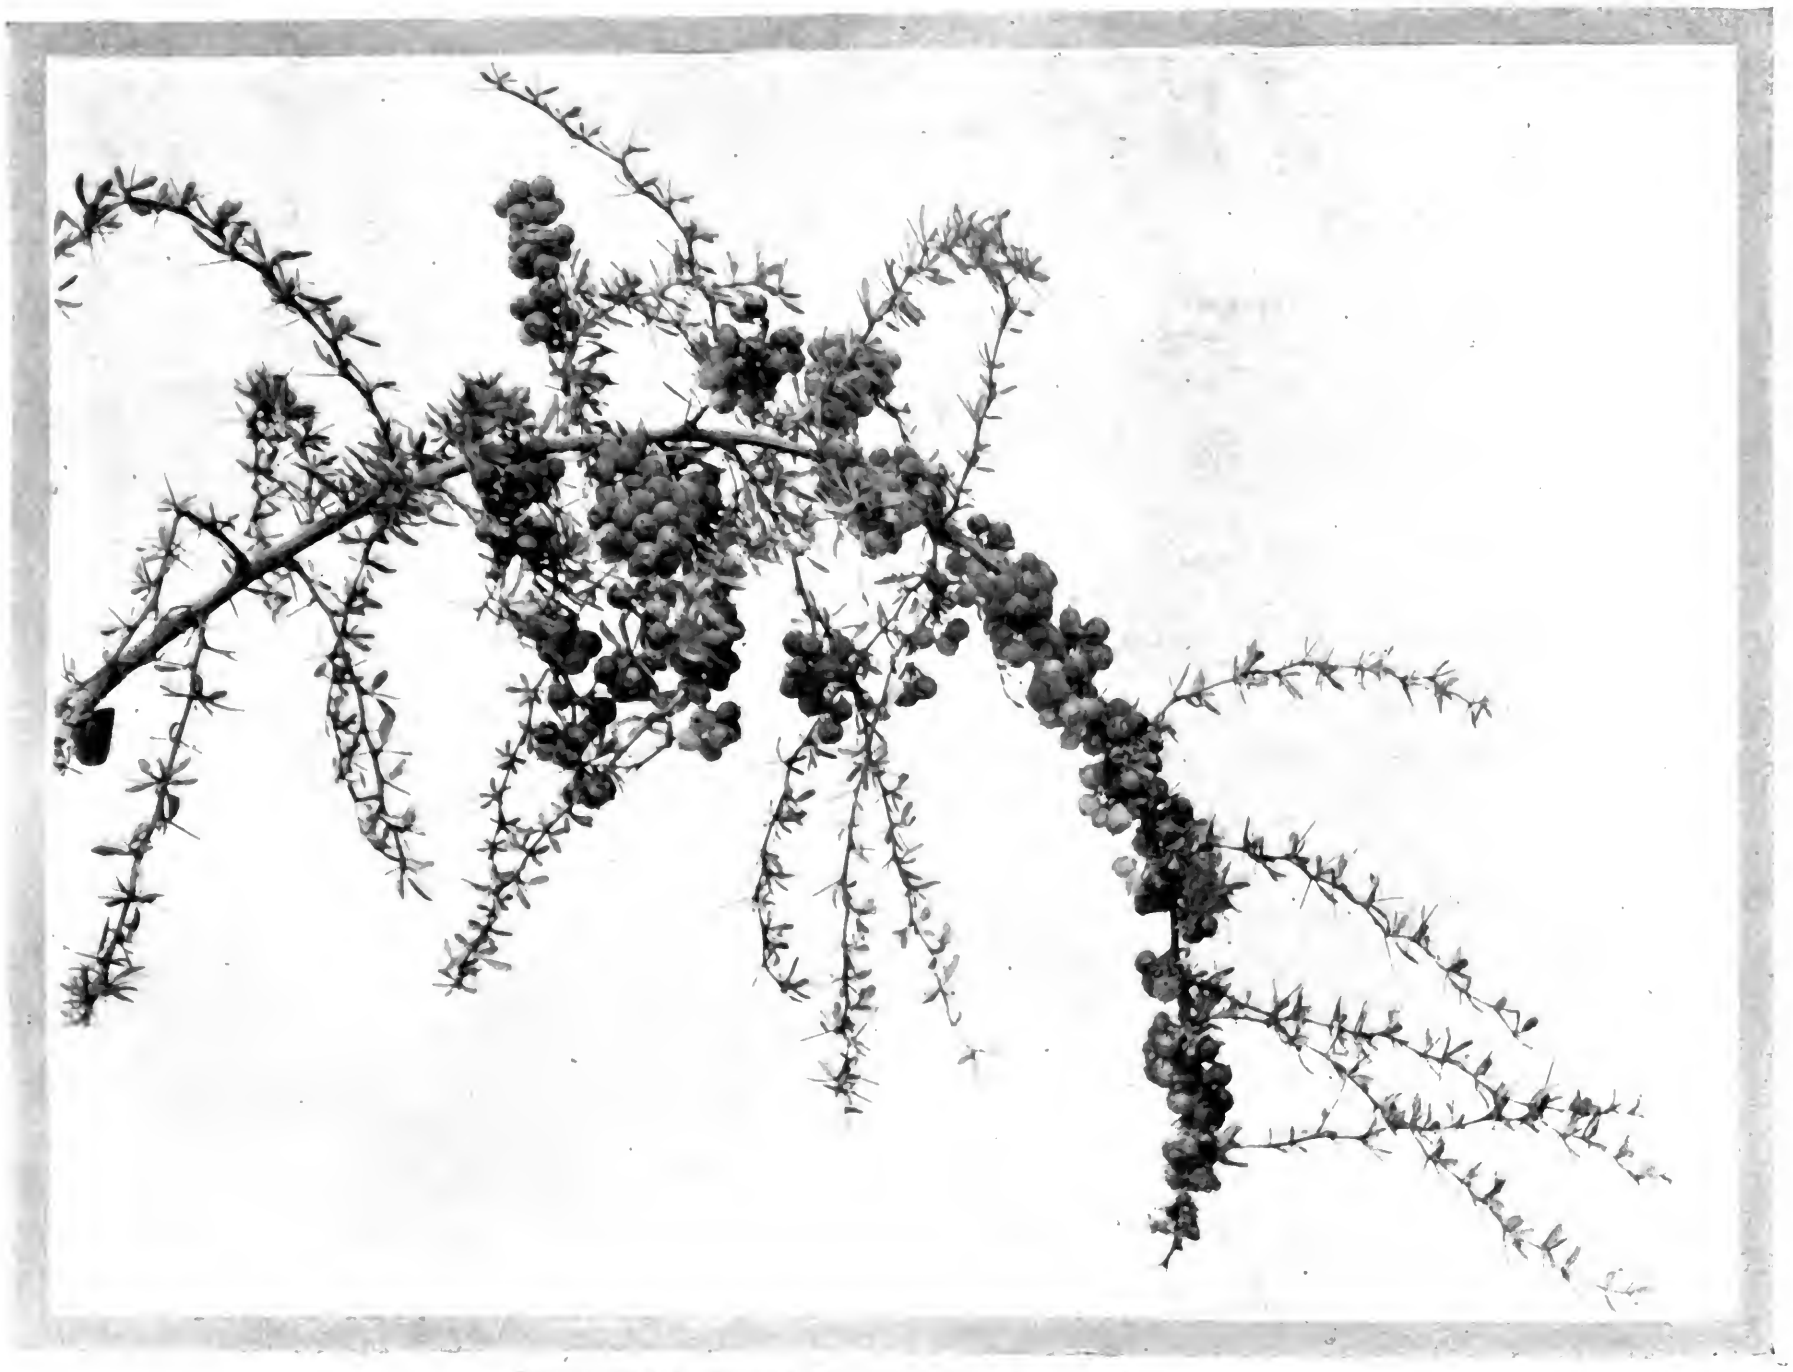
your "armour" when you are preparing to tackle the hybrid sweet briars. I must plead guilty to leaving these to the gardener's tender mercies, and he usually bears some honourable scars on face and hands for some days after his annual work among them.

Zephyrine Drouhin bears its deep rose-pink flowers freely from early summer till late autumn. No rose has a sweeter scent. And roses for hedges should be fragrant, or a great part of their charm is lacking.

For this reason, among many others, the Rugosa roses make ideal hedges. These roses are very hardy, and are not so particular as to soil or situation as are most roses; they will do well when pruned hard or when merely thinned, and their young shoots trained down, as was recommended for the Penzance briars; they require no

quite first class. I have even noticed our old retriever, who has a partiality for wall plums and ripe pears, sampling the Rugosa berries by way of variety.

The little double Scotch roses make a capital dwarf hedge, thick and brown and bushy through the winter, covering themselves with their tiny leaves in spring, and in May breaking forth into innumerable buds of pink and white, which have a most delicate fragrance, suggestive to me of fresh rose-water, a very "gentle" smell, as a friend of mine describes it. Unfortunately the blossoms are easily spoilt by wet weather, but in a fine May, such as that of 1912, there is no prettier garden sight than the little Scotch briars in blossom. They are particularly useful for a dry situation. There is a double yellow, which seems rarer, and is certainly not so easy to



FRUITING BRANCH OF BERBERIS WILSONÆ.

A handsome Chinese shrub, elegant in growth, and bearing coral-red fruits. Introduced by Messrs. J. Veitch and Sons.
(See page 28.)

I am inclined to think they do better grown in this way than as bushes, though here I am at issue with Mr. Herbert Molyneux, who, some two years since, advised us to plant a hedge of the hybrid Bourbon, Zephyrine Drouhin. These are arranged in a double row, and have made already a thick hedge. At present it is about three feet high, but we hope it will soon reach the height of six feet, which it has done in Mr. Molyneux's garden. Everyone who comes into the garden notices it—the foliage is so dense and beautiful. In the springtime the leaves show innumerable shades of glaucous blue, bronze, and cherry-pink, and they are retained very long into the winter. The stems are thornless, which, to those who prune their own roses, is a great joy. You may leave your gloves behind when you go to prune or train Zephyrine Drouhin, but must put on all

stakes, as their growths are sufficiently upright and stout to withstand all winds and weather without support; their foliage is dark green, thick and abundant in summer, and changes to the loveliest of soft yellows and russet browns in autumn. The flowers, which come very early, and in many of the varieties are produced throughout the summer, are delightfully fragrant. They are not "fast of their smell," as Bacon says the crimson roses are, but scent the air around them, so that it is very pleasant to have a Rugosa hedge running up to a frequented pathway, and when the flowers have faded they are followed by large and brilliant red heps, which light up the garden in autumn, as long as the birds can resist their attractions; but from the early attention the thrushes and blackbirds pay to them I fancy their flavour, from a bird's point of view, must be

grow. The variety Stanwell Perpetual well deserves its name. It begins to bloom in May, and at the end of December some of its sweet-scented pale blush flowers were still to be found. It is not so compact a grower as the summer-flowering varieties.

In writing on rose hedges Mr. Molyneux has given an alluring picture of a hedge of Rosa altaica (R. spinossima grandiflora). The loveliness of its tender green, and its arching sprays of large single creamy flowers, has a charm which cannot be conveyed in words, but which makes a lasting impression, albeit its actual beauty in the garden is short-lived. Rosa altaica requires very little pruning, and can be propagated from suckers. It bears a few flowers in late summer, but the leaves, after turning a dull russet-brown, fall rather early, and the shrivelled brown-black berries hanging alone on the leafless stems

have to me a somewhat melancholy appearance in the autumn, so that, beautiful as it is, I would plant my hedge of Rosa altaica in that part of the garden which is planned for spring and summer effect. The same conditions will apply to many of the rose species if used as hedges, such as Rosa sericea and R. serisea pteracantha. These would make almost impenetrable hedges, guarding the place with their huge translucent thorns from any outside intruder; but their pretty four-petalled white flowers are short-lived, and though followed by bright orange or scarlet berries in July, these, too, are quickly shed, and the true form and beauty of the slender spreading branches would be spoilt by the pruning necessary to keep a hedge in good trim.

The hardier of the China roses, especially the old pink China, make a good and perpetual-flowering dwarf hedge, and do not object to being pruned and trimmed to suit this purpose. And, no doubt, some of the stronger Polyantha varieties, such as Marie Pavie, with its pretty delicate China pink flowers and ruddy shoots, could be used in the same way. I have never seen satisfactory hedges of any of the H.T. roses, though we have experimented with Gruss an Teplitz, Gustave Regis, and others; they seem to have an innate tendency to get leggy and bare, and the foliage is scarcely close enough for the purpose.

Where varieties for tall hedges of dense foliage are wanted they must be selected from among the Ayrshires, the Multifloras, and the Wichuraianas. The foliage of many of these is almost evergreen, and for one period in the summer they clothe themselves with countless blossoms. They also have the merit of growing very rapidly, and are specially suitable for a position on the north of the rose garden. But their large rods require some wooden or iron structure to train them to, and, consequently, strictly speaking, they are more adapted for screens than for hedges. If planted in thoroughly good soil, and attended to in the matter of watering, they may be trained to grow over hedges of laurels and other evergreens.

Before planting a hedge of any sort of rose the ground should be trenched three feet deep, and plenty of top spit and manure incorporated with the lower part of the soil. The plants should be got in, if possible, in November, and the following March or April should be cut down pretty close to the ground, so as to ensure a dense growth at the base of the hedge. The distance apart they should be planted depends upon the variety, from one foot apart for the Chinas and Polyanthas, to, possible, three feet for the Ayrshires and Wichuraianas.

The subsequent treatment consists chiefly in cutting out the old wood and tying down and "laying in" the new, so that any tendency the variety may have to get leggy may be counteracted; for the beauty and use of a rose, as of any other hedge, depends largely on its being well furnished at the base.

Much more might be written on this subject. A description of the different varieties of the Rugosa most suited for making rose hedges would of itself fill many columns. But my object has been, not so much to recommend special varieties, as to suggest to the rose grower, when planning shelter for his garden, to look for himself among the many classes of roses where he may find shrubs as well suited to his purpose as can be found in any other family of plants.

WHITE LADY.

CROSSANDRA UNDULÆFOLIA.

This attractive acanthaceous plant, which was given an Award of Merit at the meeting of the Royal Horticultural Society on July 16, last, is, though not much grown, by no means a novelty, having been distributed by the late Mr. William Bull, of Chelsea, in 1881. It was by him received from Southern India, where it is said to be much grown, especially in the neighbourhood of the temples.

CROSSANDRA UNDULÆFOLIA.
An attractive plant, thriving in the plant stove or intermediate house, and bearing brilliant orange-scarlet flowers.

Like many Acanthads, it is a plant of an upright, sparely-branching habit of growth, and will flower freely when about eighteen inches in height. The erect stem, which is of a half woody character, is clothed with ovate acuminate leaves, about six inches long, of a deep shining green, with wavy edges. From this latter feature the present specific name is derived, though it was at first known as Crossandra infundibuliformis. The flowers, which are, as in many of its relatives, borne both in terminal and axillary spikes, are about one and a-half inches across, and of a rich orange-scarlet. Individually the blooms do not last long, but a succession is kept up from one spike for a considerable time. Unlike some other Acanthads the bracts are in no ways showy. Though the award was made during the summer, the flowering period of this crossandra is not limited to that particular period of the year, as blossoms are produced at different seasons, though more freely in summer than at any other time.

If the strongest shoots are struck they may, as neat unbranched plants, not more than a foot high, be flowered in pots four and a half inches in diameter. S. W.

EARLY VEGETABLES FROM SEEDS.—II.

Carrots.

No forced vegetable, in my experience, needs more care in the matter of soil than the carrot if clean, shapely roots, with fine skins are to be obtained. Less difficulty is experienced with fine-textured soils composed largely of sand; but even then the condition of the soil at the time of making the beds materially affects the crop, and in the case of soils naturally less suitable for growing carrots, the results are even more deeply marked. Newly sifted soil will not, in many cases, alone give good results.

In all early forcing of vegetables it is well to have a good stock of waste soil under cover, but with carrots particularly so, if the best results are to be obtained. I would even go so far as to recommend those who find difficulty in procuring roots with fine skins to secure their soil in September. Choose a dry day, and skim the garden of an inch or so of the surface soil, in places where it is good and a fine tilth has been obtained. Place under cover. On wet autumn days this soil may be sifted through a quarter-inch-mesh sieve, and placed in readiness for use at the end of the year.

No amount of sifting will bring the soil to such a fine state of division as occurs under good cultivation together with the aid of the weather, and this surface soil, when it embodies a good percentage of finely divided humus, and the stones and gravel have been removed, forms an ideal compost in which to grow these roots.

Sifted potting soil will sometimes prove satisfactory, but there are differences in old potting soils, and often strong side fibres, with a root of ribbed outline, are the result. Not that this detracts from their value on the table, but it certainly reduces their value in the market.

The first sowing of carrots may be made the last week of the year or in the first few days of January. The necessary amount of leaves and manure having been made up into a good bed, six to nine inches of soil is placed on it, made level, and pressed moderately firm. If obtainable, some fine burnt ballast and wood ashes may be mixed in the soil, as it will assist the carrots to attain a good colour—a point where produce is marketed. The drills are drawn half an inch deep and six inches apart, and the seed sown thinly. Before covering in, other drills may be drawn between these, and sown thinly with a small, quick-growing radish. If the intention is to prick out a crop of lettuce in the frame as well, the carrot drills must be drawn nine or ten inches apart, but I am doubtful of the economy of the practice.

With good soil, and, even presuming that only a small-growing lettuce is grown, unless the plants are strong and start away at once, there is a danger of the carrots being overgrown, and the roots being anything but uniform in size. Occasional spraying in fine weather is beneficial, and the carrots should be thinned early, spacing them two to three inches apart. Weed and prick over the soil if necessary, stirring lightly is beneficial; ruthlessly remove any radishes likely to overgrow the carrots, and clear the radishes the moment they are ready.

If the frame is a large one a few rows of the globular French forcing carrot may be sown to furnish the earliest roots; these latter need less space than the Champion Horn, which I consider to be the best for frame culture. The latter variety, under the treatment recommended, and assuming the night temperature would be from 50 to 55 degrees, would be ready in the first or second week of May. Occasional watering with sulphate of ammonia, ½oz. to the gallon, is beneficial.

Those who are satisfied with carrots of lesser quality may try their hand at the French system, in which carrot and radish seed are sown broadcast, then lettuce plants are pricked out on the top.

I have tried the method on several occasions, and have never yet brought off the three crops to my own satisfaction, and I have yet to see produce grown in that way which satisfied me, though I have understood that as many as five crops may be profitably intermingled. It looks like an instance to which the old saw of not being able to "keep your cake and eat it too," may be applied.

Lettuce.

I have already said something about this crop in treating of others. At one time I relied on a September sowing for the earliest crop, but find that in the Thames Valley the whole batch is liable to die off with collar rot, if disturbed between September and January.

Our most important sowing is made in the last half, or in the last few days, of November, in boxes, on a shelf in a greenhouse with a mean night temperature of 50 degrees. In about a month from sowing they are pricked out about an inch apart in boxes in a house a few degrees warmer. In January these are again pricked out over slight hotbeds in heated pits and frames, the plants being placed ten inches each way and intercropped with radishes previously sown very thinly. The variety of lettuce is the cabbage kind, Golden Ball. Between every four plants of the cabbage lettuce one plant of a cos variety is afterwards pricked out, a little seed of these having been sown about the same time. The variety of cos lettuce we find most saleable is the Dark Green or White Heart. Other sowings are made in the New Year, and plants from these are afterwards pricked out on a little manure covered with a few inches of rich soil, over which a frame has been placed.

The end of January is soon enough for a sowing to raise plants for pricking out on a warm border. If another kind of cabbage lettuce is grown ,two good varieties are Heartwell and Perfect Gem. These are not as quick as Golden Ball, but form better hearts, although I have had good hearts of Gem in a favourable season and on a warm border in the first week of May.

I may say I prefer shallow pits or frames to cloches for growing lettuce. Under the cloche the plants are slightly earlier, but if a good heart is required one plant requires the whole cloche to itself, and should be eaten the moment it is taken from under it; certainly, when grown by the cloche system they are anything but tempting if they are not eaten until the following day.

For growing under cloches the Early Paris Market is perhaps the most suitable. It is similar in appearance to Golden Ball, but smaller.

F. DREW.

ROSE QUEEN OF THE MUSKS.

Although the musk roses form a comparatively small group, and are less showy than the varieties belonging to the majority of the other sections, they possess much interest, and are decidedly beautiful. Their beauty is of a quiet kind, and appealed to but few in the days when the value of roses was estimated by the aid the individual blooms were able to give the exhibitor in a keen competition for the premier position. But now that a greater breadth of view is taken in the rose garden, and roses that are useful for decorative purposes duly appreciated, greater interest is being taken in the musk roses, and, as the result, they are being planted in much larger numbers annually than probably at any previous period in their history. This increased interest is doubtless, in a large measure, due to the successful efforts of the raisers in the creation of the new forms, prominent among them being the Rev. J. H. Pemberton, and Messrs. Paul and Son, of Cheshunt. Among the varieties raised by the Messrs. Paul, and now in general cultivation, is Snowstorm, a pure white, remarkable for the freedom with which it blooms in the autumn. Their most recent success among the musk roses is the beautiful Queen of Musks, which we have now the pleasure of illustrating. This variety is also remarkable for the profusion with which it produces flowers during the autumn months, and a proof of this was given by the large basket that was staged on the occasion of the National Rose Society's show at Westminster in September last. The flowers, which are produced in great profusion, are about an inch in diameter, and semi-double, and they possess the refreshing fragrance characteristic of the musk roses. The colour is blush, with yellowish centre. At the exhibition of the National Rose Society referred to above the variety was regarded with much favour, and the award of a silver medal was made in its favour.

IRIS ALATA.

The scorpion iris, as this species is named, is the earliest of all the bulbous irises to flower, generally expanding its flowers before the close of the year, and in some seasons the plants bloom well in October. It was first introduced from Algiers about one hundred years ago. In the type the flowers are lilac-blue in colour, and are each about four inches in diameter, with falls from one inch to one and a-half inches in breadth, marked with a yellow central crest that is reticulated with white on either side. As with many of the bulbous irises, the species is very variable, and there are many named varieties. One of the chief faults of this iris is its often persistent refusal to flower in English gardens after the first season, though remaining in apparent health, and throwing up its strong foliage vigorously year after year. A Cornish friend says that the only way to assure annual blooming is to purchase fresh bulbs every year, and to throw them away after they have flowered, but this is a practice that few would care to adopt. It is no uncommon thing to see a clump in seemingly perfect condition that is said not to have flowered for six or eight years. The best chance of blooming it continuously is to plant it in a raised border in front of a wall facing south in a compost of sandy loam, leaf-mould, and peat.

WYNDHAM FITZHERBERT.

THE WEEPING DOUGLAS FIR.

Although nearly a century has passed since the famous traveller and collector, David Douglas, introduced the handsome and useful fir that bears his name to this country, no contribution to the genus to which it belongs can well be regarded as its superior. Vigorous in growth and noble in aspect, Abies Douglasi is well able to contribute appreciably to the charm of park scenery, provided the conditions of soil and climate are favourable to the trees attaining their full development. In some parts of the United Kingdom, more especially Scotland and Ireland, it is regarded with much favour as a timber tree, with the result that large areas have been planted, and the woods and plantations formed with it constitute a distinct and pleasing feature of the scenery. The Douglas fir is less useful in England than in the other two parts of the kingdom as a timber tree, because of the liability of the leaders to injury when they are fully exposed to the cold winds that are usually experienced early in the year. It may be that the trees, in common with other conifers, fail to make so vigorous a growth as could be desired in inland districts owing to the atmospheric moisture being insufficient during the season of growth. On the cooler soils of the north and west of England it grows in the most satisfactory manner, and many are the fine specimens that might be mentioned. There are some good trees in the Thames Valley, and the specimen at Dropmore has a height of over 120 feet, and is the tallest in the kingdom.

In the North of Scotland the Douglas fir has proved so satisfactory that large numbers of trees have been planted for beautifying parks and pleasure grounds, and many woods and plantations have been formed for economic purposes.

During the long period that has elapsed since the Douglas fir was introduced to this country a few well-marked varieties have made their appearance, and have been given a place in those gardens in which some attention has been devoted to conifers. One of the most remarkable of these is the weeping form known as Abies Douglasi pendula, of which there is a magnificent specimen in the gardens of Bury Hill, Dorking, the charming residence of Robert Barclay, Esq. This, as will be seen from the accompanying illustration, has a somewhat slender and perfectly erect trunk, with gracefully drooping branches, which are more dense than are those of the specific form and distinctly glaucous. There appears to be no record of the introduction of this variety, but it must have made its appearance within a comparatively short time of the distribution of the species. The latter, as already intimated, was not introduced until 1828, and before the middle of the last century the coniferous trees which form so important and interesting a feature of the Bury Hill gardens and grounds were planted by the grandfather of the present owner, who was greatly interested in conifers. This tree, as evident by the height to which it has attained, was probably planted about 1840. The variety glauca is smaller in growth than the type, and the leaves are more glaucous than the other forms. Standishi has silvery leaves, taxifolia has leaves of greater length and deeper in colour than those of the type, and Stairi has pale yellow foliage. The best of the varietal forms for general planting is the one herewith illustrated.

ARBUTUS UNEDO.

To those who fully appreciate uncommon beauty and interest in the garden, a striking instance is much in evidence at present in the familiar Strawberry Tree (Arbutus Unedo). The fruits, which are its greatest ornament, hang in pendulous clusters, and are of a large size, being nearly circular, granular on the exterior, and, in the ripe fruits, coloured a vivid red; the transition stage from the normal green is marked by lemon and orange, and it is these shades of colour, in combination with the advanced stage, that proclaims this fine evergreen as one of the most handsome among all arborescent vegetation. Its period of greatest beauty is during October, November, and early December, as at this season, not only are the fruits at maturity, but the flowers are also in evidence, a double event that is by no means common among plants at any time. It is a native of the West of Ireland and Southern Europe, and flourishes in coastal districts. S.

ABIES DOUGLASI PENDULA.

A splendidly-developed specimen of this elegant tree in the gardens of Bury Hill, Dorking.

CHRYSANTHEMUM JULIET.

At the second of the two meetings held by the Royal Horticultural Society in October last Messrs. Cragg, Harrison, and Cragg, the well-known market growers, of Heston, exhibited a small, but extremely interesting, collection of cut flowers of chrysanthemums that bloom during the autumn months. The collection was of interest because of the outstanding merit of the varieties included therein, the high development of the blooms, and the effective manner in which they were staged. The chief interest was in the varieties which have blooms equal in size, form, and colour to those of the best of the decorative varieties that bloom in November, and are, therefore, of much value for the production of colour effects in the garden after the usual summer flowers have run their course, and for the supply of cut flowers for indoor decoration. Especially noteworthy in the collection were Cranfordia, a yellow variety, with large reflexing blooms; Cranford Pink, of the colour indicated by its name; Dolores, bright terra-cotta; Hullicot White, an excellent pure white flower; Mrs. Beech, red-bronze; and Juliet. The last-named is an exquisitely beautiful variety, the blooms four or more inches in diameter, and the colour bright rose-red.

CHRYSANTHEMUM JULIET.

A distinct early-flowering variety, with comparatively large elegant blooms of a pleasing rose-red hue.

BERBERIS WILSONÆ.

This is one of several new barberries which have been introduced from China during the present century. Seeds were first sent home by Mr. E. H. Wilson during his first Chinese journey, when collecting for Messrs. J. Veitch and Sons, and the plant was named in honour of the collector's wife. Perfectly hardy, and of a free habit of growth, it forms a many-branched shrub a few feet high, clothed with small, obovate, deciduous leaves, and rather long sharp spines. Its golden flowers appear with considerable freedom about May, and they are succeeded by large numbers of coral-red berries, which ripen in August or early in September, and hang in good condition for several weeks, usually until taken by birds. A glance at the accompanying illustration will be a sufficient guide to the free-fruiting qualities of the shrub, although, unfortunately, the bright colour of the berries cannot be shown. Like other barberries, it grows well in any good garden soil, and after planting gives little further trouble, for pruning is rarely necessary, and any that may be required is in the form of thinning. The shrub may be used for a variety of purposes, for it is equally suitable for shrubbery planting, beds, and isolated specimens, whilst if space is available on slightly sloping ground, it might be planted to form a large group. Seeds are ripened freely, and they form a ready means of increase. W. D.

NEW PLANTS.

CATTLEYA TITYUS.

By crossing Cattleya Enid with C. Octave Doin this handsome form has been produced. The flower shown was of largest size, with broad mauve-purple sepals and petals and a wide, fully expanded lip, with a rich purple apex and yellow throat. A.M., R.H.S., December 17. H. S. Goodson, Esq. (gardener, Mr. Day), Fairlawn, Putney.

CARNATION BENORA.

A distinct and beautiful perpetual-flowering variety that has obtained so much attention since it has made its appearance at the exhibitions as to suggest that it will become highly popular. The plant has a good constitution, and is free and continuous in flowering, and the blooms are of large size and borne on long stiff stems. The latter are also of good form and have a fine petal, which is freely marked with carmine-red on a pure white ground. A.M., R.H.S., December 17, 1912. Messrs. Stuart Low and Co., Bush Hill Park, Enfield.

PINUS FLEXILIS.

An extremely rare pine in British collections, the finest examples being two specimens at Terling Place, the seat of Lord Rayleigh, and a group of four trees in the Kew pinetum. This species was first discovered by Dr. Parry in Colorado near the base of Pike's Peak in 1820, and introduced to cultivation 41 years later. The tree attains a height ranging from 40 to 50ft., the finest of the Kew specimens being 33ft. high, and is distinct in character. The branches are upturned at the ends and present a candelabra-like appearance. It thrives in the indifferent soil and atmosphere of Kew, and is therefore well deserving of the attention of planters in districts not particularly favourable to tree life. "Bot. Mag.," t. 8,467.

PRIMULA JULIÆ.

A pretty Transcaucasian primrose, which was sent to Kew by Professor Kusnezow, director of the Botanic Gardens at Dorpat. It has orbicular leaves and purplish-rose flowers, with red blotches round the eye. It flowered for the first time at Kew in the spring of last year, and the flowers were produced in April. This species is closely allied to Primula acaulis, from which it differs chiefly in the shape of its leaves. Although pleasing in appearance, it is not equal, for the production of displays of colour in the garden, to the many fine single primroses now available. "Bot. Mag.," t. 8,468.

AKANIA HILLI.

A distinct and handsome plant thriving in the greenhouse and of considerable interest. The Kew plant was received from Mr. Linden in 1872, under the name of Lomatia Bidwilli, and was planted in a border in the Mexican House. Here it has grown freely, and during the forty years has developed into a graceful tree 20ft. or so in height. Not until February, 1912, did it show any signs of flowering, and when its inflorescences were developed from the hard woody stem, it was seen that the plant was not a lomatia but Akania Hilli. The leaves are unequally pinnate, and range from 12 to 24in. in length. The flowers are borne in panicles, are about an inch in diameter, and pure white, with prominent stamens. "Bot. Mag.," t. 8,469.

LISSOCHILUS ANDERSONI.

An interesting and rather attractive species, with medium-sized flowers, having greenish-white sepals and petals and a white labellum marked with rose-coloured lines. A native of the Gold Coast, where it grows in open, sunny positions that are converted into swamps during the rainy season; it was sent to Kew by Mr. J. Anderson in 1908. The species of Lissochilus have but little horticultural value because of the difficulties with which their cultivation is beset. "Bot. Mag.," t. 8,470.

ROSA OMEIENSIS.

A distinct rose that is regarded as the Eastern representative of the Himalayan Rosa sericea; but it differs from that species by its more numerous, relatively narrower leaflets, its usually smaller flowers, and the thickened yellow fruiting pedicels. The stems are thickly set with spines, the leaves are finely divided and elegant, the single flowers white, and the small oval fruits brilliant red, with green calyx, lobes and yellow pedicels. This rose was first discovered twenty-five years ago by the Rev. E. Faber on Mount Omei, Szechan, at an altitude of about 8,000ft. Subsequently it was met with in the neighbourhood and also on Fang Mountains, Hepeh, by Mr. A. Henry, who describes it as a large spreading bush, ranging from six to eight feet high, and forming thickets on the mountains. To Messrs. J. Veitch and Sons belong the credit of introducing this rose through their collector, Mr. E. H. Wilson. "Bot. Mag.," t. 8,471.

CARNATION BENORA.
White with carmine-red markings. A.M., R.H.S., December 17, 1912. Messrs. Stuart Low and Co.

Dwarf Polyantha Roses in Pots.—These roses are charming when grown in pots, and, what is more, under such conditions their flowering season extends late in the season. On December 3 a group of them formed a bright and pleasing feature at the Horticultural Hall, the variety Jessie being, as was the case out of doors earlier in the season, the most conspicuous of all. —W.

CORYLOPSIS SPICATA.

One of the daintiest shrubs that adorn our gardens in spring is Corylopsis spicata, a member of the witch hazel family, and sharing their characteristic in regard to the flowers, which appear on the naked branches in advance of the leaves towards the end of February or early in March. It forms an exceedingly neat and attractive bush, attaining a height of some three to four feet, and produces its sulphur-tinted flowers on the last season's wood. These are in the form of drooping catkins, and, with the accompanying sheaths, which are also coloured like the flowers, are borne in such profusion as to hide the greater part of the plant when in flower.

Corylopsis pauciflora is another species worthy of inclusion among choice shrubs. It grows rather taller than spicata, but in other respects bears close resemblance to it, the catkins being similarly coloured with from two to four flowers to each, and, like the first-named species, these are borne exceedingly free upon the last year's wood. Both shrubs are quite hardy, but owing to the early season at which they bloom a sheltered position should be selected.

THOMAS SMITH.

DEEP CULTIVATION OF SOILS.

Deep-rooting plants are not grown in ordinary garden soils without a large number of difficulties cropping up to handicap the cultivator, and, as a remedy for all these attendant evils, the practice of trenching is most commonly advocated. Amateurs particularly often imagine they have solved the secret of growing exhibition produce of the highest quality by stirring up the soil as deeply as possible and placing manure at the bottom at a good depth below the surface. Haphazard tillage of this kind, however, often does more harm than good, and I could enumerate a great many cases where a considerable amount of damage has been done by injudicious trenching.

Some of the best and richest loams have underneath them a heavy, retentive clay or an adhesive gravelly subsoil, while, on the other hand, there are many of the lighter loams which overlie a poor sandy subsoil. Obviously, therefore, any kind of cultural work that is going to bring any of these undesirable subsoils to the surface cannot be reckoned to improve the conditions, but rather the reverse, since the seedlings are bound to suffer if they are brought into contact with this undesirable medium. What seedlings want in their youngest stages of growth is plenty of nourishment, and if the soil in which they are growing is not suitable to hold and retain artificial plant food, then the seedling must inevitably flag and sicken.

A very good illustration of this may be observed in the case of celery, especially in such cases where amateurs and others of more or less limited experience dig a trench, and place the young celery plants in the newly-turned subsoil at the bottom. Of course, the uncongenial nature of the latter medium prevents the seedlings making any headway, and they naturally remain stunted, much to the surprise of the grower; while when the autumn at last arrives there is to be considered the labour entailed in earthing up. Instances of such injudicious treatment of soils are not generally noticed amongst experienced growers, of course, but there yet remains a host of gardeners to whom all soils are alike, and all demand similar treatment. Here it is that the cause of their many failures arise.

Some years ago I had the fact impressed on me very thoroughly that better results follow the digging of heavy retentive soils in the spring, after the heavy deluge of rain during the winter, than the second digging of heavy soils that had been winter trenched. It was clearly noticeable in the former case that the ground dug drier, and was much more easily worked than the soil in the latter case; also it was more mellow in character, and altogether superior as a medium for the rapid and healthy growth of young seedling plants. Anyone with an observing eye can easily understand that the heavy soils which were dug in the winter retained a larger amount of moisture, and, therefore, would be less amenable to spring tillage than the same kind of soil that was left until the early part of the year.

The condition of the heavy, retentive soils that have been dug in the winter is quite the reverse of desirable; they are generally soggy and wet, and need a lot of forking over in the spring in order that the moisture may dry out to some extent. Even then, it is often impossible to secure a really satisfactory seed bed. Indeed, there is no doubt at all as to which is the best mode of treating heavy soils. I myself put the matter to a practical test for a good many seasons, and in all cases I have been bound to admit that the best produce has been grown on soil that has merely been cleared of weeds in the autumn and left undisturbed until the following spring, afterwards being dug over thoroughly in readiness for planting during March and April.

All practical growers are familiar with the evil results that follow the excessive treading or kneading of seed beds when the ground is wet, especially where the soil is at all inclined to be heavy and retentive. If, therefore, the work of digging and trenching cannot be taken in hand before such time as the ground has become saturated with moisture, then it is certainly advisable to postpone it altogether until the ground works more freely. Particularly is this so in the case of ground that is covered with snow.

The proper object and purpose of trenching a piece of ground should be to effect a gradual improvement in the subsoil by incorporating with it a liberal dressing of well-decomposed manure as the work proceeds. The condition of the fertilising material that is used for this purpose will, of course, have something to do with the success or failure attending this method of improvement. Thus, cold, damp manures like cow or pig manure should be used on light, open, and unretentive soils, while a lighter-textured material, like horse manure, will prove of greater advantage on a cold heavy and retentive soil.

There are other advantages, of course, claimed for the work of trenching. The difficulty in performing the work, however, is not merely encountered in regard to affording the plant roots an easier medium in which to strike and penetrate downwards in search of moisture and plant food ingredients, but is concerned also with the improvement of existing soil conditions such as will enable the moisture from below to rise with ease to the surface of the ground. Evidently, therefore, the ground should be moved periodically so as to assist capillarity. J. C. N.

When to repot Nerines.—There seems to be a decided conflict of opinion as to the season of the year in which it is best to repot nerines; and, anxious to learn the opinions of others, I put the question to a very successful cultivator of these beautiful South African bulbs, and his answer was that the best time to repot nerines was not to do it at all. This may appear somewhat contradictory, but he wished to convey the idea that nerines should be repotted as seldom as possible, providing the roots are in a good state. When repotting was absolutely necessary he preferred to carry out the operation directly the flowers have lost their beauty; and that, after a series of experiments, is when I prefer to do it. As one may desire to allow the bulbs to remain undisturbed for years, it is most essential the soil be of a lasting nature, such as a good yellow loam, lightened by a liberal admixture of rough silver sand.—S. W.

CUT FLOWERS IN WINTER.

When the chrysanthemums are over there is usually a scarcity of flowers having long stems that are suitable for cutting, and unless special preparations have been made for their production a dearth will be felt. Liliums, such as candidum, longiflorum, and speciosum, may be had in bloom, provided retarded bulbs were procured and potted up sufficiently early to allow time for their flowers to develop. Tuberoses may also be had in flower, while the calla, if well grown, will be furnishing us with ample white spathes. All the foregoing, however, are heavy in appearance, and only suitable for large vases. Some object to L. candidum on account of its powerful fragrance, while tuberoses are objected to because of their heavy appearance.

Where there is ample glass there should be no difficulty in keeping up a supply of perpetual-flowering carnations. The flowers of these are usually borne on long stems, and if disbudding was taken in hand early the individual blooms should be of fair size, borne on stout stems, and will present a light, graceful appearance if arranged loosely in tall vases. Carnations of this type have come very much to the front of late years, and when well grown give a wealth of bloom, but to have them in perfection during the short days houses should be set apart specially for their production. Roses are also great favourites, but these, like the carnations, need a light airy structure to grow them well. Flowers of a flimsy nature on short stalks are of little use for decorative purposes. The stems should be of adequate length to allow of the flowers being arranged with effect. It is not necessary to grow a number of varieties; better by far have enough of one of exceptional merit to give sufficient blooms to furnish a vase nicely, rather than have a mixture.

There is a great art in arranging flowers. One person will furnish a vase nicely with half a dozen or a dozen blooms, while another will not make the same so effective with double the quantity of flowers. Freesias are very useful for cutting, and though the flowers are not showy, their sweet scent is always appreciated. It is not difficult to have these in bloom at Christmas, provided the bulbs are potted up sufficiently early. When potted they should be stood in a cold frame, and have the lights put over them. It is not advisable to pot too deeply. Forcing should be done gently, otherwise the plants will have but little substance in them. Narcissi of various kinds may be had in bloom sufficiently early to take the place of chrysanthemums, provided bulbs of good quality are grown. These should be potted up in August so as to allow time for them to grow strong. Those of the tazetta clas sare very useful, especially if they have long stiff stems. To have these bloom very early, that is, at the commencement of the New Year, the bulbs, when rooted, should be placed in a cold frame, and allowed to remain there so long as the weather is mild. If it is found necessary to introduce them into heat, no more should be applied than is requisite to keep the growth moving. Treated in this manner the stems will be stout, and the flowers of far more substance. Bulbs, too, of the early trumpet kinds may be had in bloom in January, provided they are potted in August, and brought forward in cold frames. Flowers to stand well when cut should not be subjected to a high temperature when growing, as that makes them too delicate to withstand the sudden change to which they are usually subjected.

Roman hyacinths play an important part in the cut flower business early in the year, thousands of bulbs being grown specially for forcing, as it is termed, but there is no need for forcing, provided the bulbs are planted early, and afterwards placed in a cold frame. Treated in this way we could always have them in bloom early in January, or by Christmas, if need be. If not in flower at the time required a few days in a gentle heat will induce the buds to expand. Lily of the valley is always in demand, and since retarding the crowns from one season to another has been adopted there is no difficulty in having flowers at any season of the year. I well remember when I was a boy the trouble we had to induce the crowns to bloom. Now, not only are the roots kept in a dormant state from one season to another, but special cases are make for growing or forcing them into bloom. Lily of the valley, as sold in the market, is grown in the dark, therefore the foliage is blanched. That sold with the flowers is usually from other plants.

Tulip culture now forms an important industry, but none excepting those varieties with long stems find favour with the florists for cutting. These are grown in the dark to cause the flower stalks to become drawn, but are exposed to the light gradually just before the buds expand, so as to put colour into the blooms. There are several varieties that respond wonderfully to this treatment. As the days lengthen and the sun has more power, there are a host of plants that will bloom in a cold frame. Anemones are among them; the wonderful colouring in some of these flowers is astonishing. A. coronaria and A. St. Brigid are very useful for growing in cold frames, where they will bloom through the dull winter months. They may be readily raised from seed sown in the spring and pricked out into the frame as soon as they are large enough to handle. The stems of these are usually from nine inches to a foot in length, therefore are quite useful for arranging in vases.

Those who have the command of heated houses would do well to grow a good batch of calanthes of different kinds. When well grown, having spikes from five to six feet in length, there is nothing more useful for arranging in large vases. The spikes have a light graceful appearance, and as the flowers last such a long time in perfection there is no need to be rearranging the vases every two or three days. We have often had spikes in the rooms for six weeks before it has been necessary to remove them. The colour of the flowers, too, is very pleasing, especially those of Bella. The white varieties are very fine, and look well arranged with light sprays of Ruscus racemosus, which helps to keep them in position. Where space will admit a house of these should always be grown for supplying cut bloom.

No doubt there are many other kinds of plants that are useful for supplying cut flowers early in the season, but we will only mention one other, and that is the stock. The delicate perfume of the stock is always appreciated, and as the plants are of such easy culture, it is a pity they are not more largely grown for winter flowering. The seed of such varieties as Beauty of Nice should be sown in July, or early in August, according to the time the plants are wanted in bloom. The plants, after potting, should be grown in a cold frame so long as the weather continues mild, but must have a gentle heat during severe weather to induce the flowers to expand freely.

H. C. P.

VARIETIES OF VARIATION.

The seed of a plant and the egg of an animal are practically identical in their nature, and equally marvellous. Each consists roughly of three items, a fertilised germ, a store of nourishment, and a protective envelope. Each is the result of a conjunction of potencies derived from two different sources, and each contains the two sets so combined that, given congenial conditions, a new individual will be developed resembling, as a general rule, the parental form. We say as a general rule because there are exceptions, and these exceptions are of two diverse kinds.

In the first case, the parents may be of dissimilar type to each other, i.e., either different varieties of the same species, or different species entirely. In this case, the result of the combination may be an intermediate form of individual showing more or less the peculiarities of both parents, but resembling neither exactly; or it may yield one of the parental forms apparently unmodified, but which will nevertheless show by its offspring that it contained latent characters as well as patent ones, the other parental form asserting itself again. The other kind of exception is far more puzzling, since it is that which embraces sudden "sports," in which quite new characters not only appear, but are so fixed in the plant's system that its offspring may reproduce the new type without any reversion to the old one. With hybrids, or crosses, of the former category the cultivator can usually form some idea of what the result may be, and he can work to more or less definite ends, but with the latter category he can exercise no control at all.

He may make a pure, i.e., unmixed, sowing of a hitherto perfectly constant plant, and among the resulting brood there may be a quite distinct form, indubitably of that particular species, but departing from its special characters in very marked ways. It may be a solitary specimen, and is so, as a rule, but cases are recorded in which several have appeared, and all identical; or more than one new type may present itself, each being distinct of its kind, and by no means gradations leading up to the more marked. This absence of gradational forms is, indeed, one of the most striking features of "sports"; they form, really, cases of sudden, or jump, variations, which until quite recently were merely regarded as monstrosities incapable of playing any rôle in the origination of species proper. Investigation, however, has shown that, to all intents and purposes, each such "sport" is an initial species in itself. It possesses all the faculties of a true species, viz., adherence to type, distinctness of character, and permanent constancy of reproduction. All that it needs to become an established species is the capacity of holding its own in the struggle with its congeners ,and other environmental factors; and considering the great number of such "sports" which are known to occur under wild conditions, and the fact that they vary in all directions, it would be a very strange thing indeed if, in the course of evolutional æons, some of these had not possessed the capacity indicated, and thus contributed to the number of distinct species extant.

The old proverb, "Natura non fecit per saltum" is thus seen, like most rules, to have its exceptions, at any rate optically, though we are so absolutely ignorant of the origin of these sports, since they are only recognisable when it is too late to investigate such origin, that it would be unwise to assert that no gradational influence in the mother plant has led up to their birth. Of this, however, there is absolutely no evidence, and our own opinion is that none will be found.

Taking a fern sport as an example, we find, amid a mass of normal ones, a single individual of very different structure. We separate it from the mass, and find it to be an unattached plant. Nevertheless, we cannot assert for this reason that it arose from a spore, since bud or offset sports exist, and the connecting link between the normal parent and the "sport" offset may have long since rotted away, or its evidence destroyed in the process of separation. Experience with spore sowing indicates the probability that "sports" usually arise from spores or seeds, since numerous remarkable forms have thus originated under culture. On the other hand, a case came under our own notice where a single frond base of a hartstongue produced two buds, which subsequently developed into two extremely dissimilar forms; while, conversely, a sowing from a wild "sport" of the same species of a merely sagittate nullified type, gave nine plants of a triple-headed corymbose form, constituting the extreme development of the parental type; the two merely sagittate basal lobes with divided tips, and the nullified heads developing such dense heavy crests as to absorb and obliterate the normal strap-like portion. Had such a form arisen in the vicinity of the parent, a gradation would have existed, but would hardly have been suspected owing to the great difference.

As much may be said of all improved or extended types which have been obtained under culture by seminal selection, but the fact remains that the most careful search in the vicinity of marked sports has always resulted negatively as regards intermediate forms indicating gradation. I have so far treated of constant variations, i.e., sports which retain their form under cultivation, and reproduce themselves truly for generations; but inconstant sports are frequently found, in which the variation is partial, thus in the Kalothrix variety of athyrium there is always a tendency to revert partially.

When, too, the spores are sown there is always a percentage of the assumed parental form, which, however, never, so far as we know, shows the Kalothrix type. The finely-cut Polypodium vulgare, known as elegantissimum, or cornubiense, has the same trick in a more marked way, since it really produces three kinds of fronds, viz., very finely cut, coarser tripinnate ones, and the normal, and these may appear indiscriminately all on the frond, or even in one sub-division. Several other "sports" act in the same eccentric fashion. These, however, are all constant in so far as they never entirely revert, and their spores reproduce the type plus its vagaries.

Chas. T. Druery, V.M.H., F.L.S.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

DECIDUOUS CALANTHES.—The various species and hybrids of the deciduous section of calanthes as they pass out of flower, should be placed under resting conditions in a position where they will obtain the full benefits of the available light. A shelf in the stove or warm intermediate house, near the roof glass, is a suitable position in which to place them. Withhold water entirely from their roots for some weeks, indeed, until the new growths make their appearance, and even then root moisture need only be sparingly given. In many gardens, owing to space being limited, difficulties are often found in storing calanthes. Under such circumstances the plants may be turned out of their pots, have all the potting compost removed, and, after shortening the roots, be laid in seed boxes or pans on a bed of dry sphagnum moss, finely chopped and freely intermixed with silver sand. Keep the plants carefully labelled, and separating boards may be placed across the box to divide the different kinds. Place the boxes in a light position, but give no water until after the new growth has fairly commenced. After a dull summer and practically sunless autumn the pseudo-bulbs of calanthes are much softer, and less matured than is usual. Every precaution should, therefore, be taken to induce the plants to ripen before they resume vitality; the result of this will be more satisfactory growth in the coming season. The later-flowering kinds, such as C. Regneri, C. Sanderiana, C. Williamsi, and others, must have sufficient root moisture to assist them in developing their flower spikes, and in the expansion of their flowers.

THE MEXICAN LÆLIAS, such as L. albida, L. autumnalis, L. anceps, L. Gouldeana, and others, that have passed out of flower should be placed in a position where they may have the full benefit of the available light. All moisture should be withheld—it is surprising the prolonged season of rest these plants require—and until such time as growth recommences they will do entirely without water. Keep the temperature cool, and admit air freely whenever the outside conditions permit. Keep a sharp look out for woodlice and other insect pests which attack the young roots. Some hollowed-out potatoes placed about the compost will attract these pests, and by the aid of a light they may be caught and destroyed at night or early morning.

PLEIONIAS.—These pretty winter-flowering plants, which have recently been in bloom, are advancing their growth to the stage when the new roots make their appearance. P. lagenaria and P. maculata are the most useful, and thrive well in a cool intermediate house throughout the year. It is not advisable to annually repot, but after the long resting season the surface moss usually dies, and this should be removed, and any top-dressing necessary should be attended to. Where repotting is required select clean, well-drained pans or pots, and use a compost of good fibrous loam, peat and sphagnum moss in about equal portions, with sufficient sand and broken crocks added to render the compost porous. Press the compost moderately firm, and suspend the plants near the roof glass.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CONSERVATORY DECORATIONS.—There should be no difficulty in keeping the conservatory gay with flowering plants during the remainder of the winter, provided batches of the earlier bulbs and other forced subjects have been brought along in suitable temperatures. The management of this structure in regard to watering and ventilating will require careful attention during the next two months. Every favourable opportunity must be taken to open the ventilators more or less, according to the conditions prevailing out of doors. Watering should be done as early in the day as possible, and unless the plants are standing in close proximity to the hot-water pipes it will only be necessary to examine them once a day for water. This work should be done by an experienced hand, as the more efficiently it is carried out the longer will the flowers remain in good condition, and, in consequence, the difficulties which exist in keeping the conservatory gay during the winter will be greatly lessened. Batches of some of the later tulips and narcissi may be introduced into the forcing house now with safety, provided they were potted early in the autumn. These, as well as all kinds of forcing plants, must be started early enough to admit of their being placed in a cool structure for a few days prior to their removal to the conservatory or dwelling.

LILY OF THE VALLEY.—To maintain a supply of these flowers it is necessary to grow retarded crowns till about the end of the present month, and batches should be introduced into heat about every three weeks. These should also be placed in a cool house for a few days before using them for decorative purposes. Ordinary crowns which have been potted up and plunged in ashes out of doors may be placed in the forcing house at the end of the month. These are not so easy to manage as the retarded crowns, and the least cultural error may cause failure. They should be plunged in a box of cocoanut fibre, and placed in a moist warm house. The box must be covered till the flower spikes are three or four inches high, when they can be gradually inured to the light. To obtain plenty of flowers for cutting clumps may also be dug up from the open ground, and placed on a hotbed in a heated pit, keeping them dark till the spikes are well above the ground.

CALLAS.—Although these may be forced into flower quite early in the year, they will give better returns if brought along close to the glass in a cool structure. They are most desirable for Easter decorations, and for this purpose they will not require more than an ordinary greenhouse temperature. They are gross in feeding, and besides having a rich compost, they require plenty of stimulants when they have made sufficient roots. Diluted farmyard drainings and soot-water will be sufficient to satisfy their needs in this respect. Greenfly is a persistent enemy of these plants, but may be kept in check by lightly fumigating occasionally with a nicotine compound.—E. HARRISS, Lockinge Gardens, Wantage.

HARDY FRUITS.

PYRAMIDAL AND BUSH FRUITS.—Where these are not making useful fruiting wood much may be done to improve matters by going well down to the roots and removing much of the old worn-out soil for fully four feet from the stems and replacing it with a good sweet suitable compost. Mellow loam with which a little manure, crushed bones, and wood ashes have been incorporated, will answer the purpose well. In some cases it might be well to take out a trench half-way round the tree at a short distance away from the stem, and remove the soil to a depth of two feet or more. Having reached a point below the roots trim the ends and relay them in various depths in good soil, doing the other half, early in autumn, which is really the most suitable time to deal with the roots of all fruit trees.

YOUNG FRUIT TREES may be planted at any time when the land is in a suitable state till the beginning of March with good results. Plant only good well-known varieties of both pears and apples, and these should be selected to keep up a lengthy supply of fruit, as without plenty of late varieties the supply is cut short. We seldom have good fruits of late pears unless the autumn proves very fine and warm, although in some parts of the country late pears ripen up well. I am this season planting more trees of President Barabe, Nouvelle Fulvie, Marie Benoist, Madame Lye Baltet, and Le Lectier, and these varieties are being given good positions on walls, and trained as cordons. Other varieties that have not proved good here will be grafted with more suitable kinds when the proper time arrives.

ORCHARD TREES.—A little timely pruning annually will do much to improve the crops and fruits. The heads are best kept well thinned, removing all cross and interlacing branches not required, so that light and air may reach the interior of the trees. If the trees have been greatly neglected let the thinning be extended over two seasons or more in preference to one very severe pruning After this work has been completed dress the heads with lime when the wood is damp, so that it may adhere, or syringe well with a solution of caustic soda according to directions given on the tins. Healthy trees of inferior varieties should be headed back in readiness for grafting when the proper time arrives. Graft plenty of useful late varieties in preference to having an excess of early soft-fleshed kinds that will not keep, and when apples are not in such demand as they are late in the season. Liberally manure trees that are growing on grass land, and keep the grass grazed very close with sheep or cattle, nothing being more harmful to the welfare of the trees than allowing the grass to attain full development and cut it for hay. Attend to the staking and restaking of young trees, and keep a sharp look out for rabbits, which will bark the stems should severe weather set in; see that the labels are made secure to avoid confusion later on. Young trees, newly-planted, will require some temporary support till the soil settles before finally staking them.

FRUIT ROOM.—The atmosphere of the fruit room should be kept sweet and the temperature not too low. Remove all decayed fruits at intervals, but do not shift more than is really necessary the sound fruits of late-keeping varieties. With us Lane's Prince Albert, Bramley's Seedling, Winter Nonsuch, and Chelmsford Wonder keep quite sound till late in the season.—H. MARKHAM, Wrotham Park, Barnet.

THE KITCHEN GARDEN.

THE SEED ORDER.—The selection and ordering of the seeds of the various kinds of vegetables is a matter of considerable importance, for a stock of reliable seeds is essential to success in the production of good crops in the kitchen garden. The question of suitable varieties should have careful consideration, as nowadays there is a bewildering array of good things from which to select. There are many who prefer ordering collections of seeds which are offered by most seedsmen; these are excellent in their way, and, no doubt, are of service to those who are not fully acquainted with the various kinds and varieties. There should be no delay in despatching the order to avoid the consequent waiting for the seeds owing to pressure of orders. The seed drawers should be carefully cleaned out in readiness for the new stock.

CARROTS.—In forcing carrots a mild, lasting bottom heat is essential. Brick pits are the most suitable for the purpose, but ordinary frames will also answer well if the hotbed is properly made up. The fermenting materials, composed of stable dung and a liberal addition of leaves to steady and

retain the heat, should be prepared, and turned over once or twice to allow the rank heat to escape. After this the beds may be formed from three to four feet deep, according to circumstances, and made firm. A layer of light sandy soil to the depth of seven inches should be put on the top of the manure. When the heat has steadied down sow seeds of some early varieties, not too thickly, in shallow drills or broadcast. Let the frame be kept close till the plants appear, then admit air by tilting the lights, more or less, according to the state of the weather, covering the glass at nights with mats, using, in hard weather, litter as well. The top heat should range from 55 degrees to 60 degrees with a rise of ten degrees in the daytime during bright weather.

CAULIFLOWERS.—A sowing at once should be made to secure early plants, using pans or boxes filled with light sandy soil. The seed should be sown thinly, as the young plants are subject to damping off, and become spindly in growth is crowded. As soon as the plants are large enough to handle prick out in boxes or small pots. Covering the seed pans or boxes with a sheet of brown paper assists germination; this should be removed when the young seedlings appear. A position in an early vinery or peach house is suitable until the young plants are established; afterwards a cool pit, where they should be placed near to the glass. At first air must be cautiously admitted or the plants may receive a severe check; as the plants make progress gradually increase the amount of air.

FRENCH BEANS.—Sowings should be made for succession according to requirements. Eight-inch pots will be found large enough for the early sowings; good turfy loam, with some spent mushroom bed manure, may be used. It is advisable when sowing to add two or three extra seeds; these can be removed if complete germination takes place. Start them in a temperature of 55 to 60 degrees, and give a higher temperature when they have germinated. A light position near the glass is very essention to success. When the roots are running freely in the soil it will be necessary to in a position where they will obtain the assist them with stimulants, which should be given weak and often.—W. MESSENGER, Woolverstone Park Gardens, Ipswich.

THE CITY OF LONDON ROSE SOCIETY.

Although the season of roses still seems afar off, the rosarian has to be up and doing at all times, especially if his ambitions tend towards showing his blooms.

The idea of forming a City Rose Society was suggested by Mr. A. E. Protheroe through these columns at the end of last season, and the idea met with such an enthusiastic response that the society now seems in a fair way to become one of the foremost in the country. Considerable progress has already been made, and the membership is increasing rapidly.

The committee have decided to hold the first Annual Exhibition at the Cannon Street Hotel, and have allotted the very satisfactory sum of £70 to be competed for in prizes. In addition, several cups are already promised, amongst them being one from the "City Press."

A schedule has been drafted, which should prove exceedingly popular, affording as it does encouragement for all classes of the community, from the amateur, growing his roses by the thousand, down to the smaller, but not less enthusiastic cultivator, whose time, means, or accommodation limit him to the possession of less than 100 plants.

Another very attractive feature, and one that should provide keen competition, is the Metropolitan section, in which only those growing their roses within certain specified distances of the Royal Exchange will be allowed to compete.

City men desiring to join this society should communicate with the hon. secretary, Mr. A. E. Protheroe, 67 and 68, Cheapside.

BUILDING IN REGENT'S PARK.

With reference to the building operations in Regent's Park, which we dealt with in our issue of the 4th inst., Lord Eversley writes: It seems to me that a very great mistake was made by the Office of Woods and Forests when, three years ago, they renewed the lease of South Villa, including in it almost the whole of the eight acres of land which under the agreement of 1883 was conceded to the use of the then lessee for the remainder of his lease, and when they allowed the erection of the six or seven enormous buildings by the new lessees, the Bedford College. I cannot believe the transaction was approved by the Office of Works, who are charged with the maintenance of Regent's Park and its amenities. If, again, the public had been informed, as was promised by the late Mr. Hanbury, I am confident that the lease would not have been concluded.

It is not, however, possible now to rectify the error. The lease cannot be set aside. The buildings are nearly completed. What we have to do is to take precautions against similar transactions in the future as regards the land temporarily attached to the eight other villas in Regent's Park, under the arrangement of 1883, together with the seven acres of land reserved for the exclusive use of the lessees of Hanover Terrace, which must be thrown into the Park at the end of the existing leases.

I admit that no decision was arrived at to this effect in 1883; but the general terms of the arrangement pointed in that direction. It was my contention at the time that this should be done at once. Mr. Gladstone, to whom the case was ultimately referred, would, I am confident, have agreed to this, had he not thought that some consideration was due to the lessees, who had enjoyed the use of the land for so many years. This led him to propose the compromise by which the lessees were to retain a part of the land for the residue only of their leases, while the remainder was thrown open to the public at once.

It seems to me that, as the leases are now within a very few years of their end, a decision ought at once to become to as to the ultimate disposal of the land in question in the direction of throwing it into the Park. If the decision is deferred fresh claims may grow up on the part of the lessees, and the Office of Woods and Forests may again come to arrangements with them, without the public having the opportunity of objecting, and these very necessary enlargements of the Park will be for ever prevented.

Begonia Beauty of Cincinnati.—The bold, showy character of this begonia, which belongs to the Gloire de Lorraine section, was freely commented upon at the first of the two December meetings of the Royal Horticultural Society, when an extensive group of it was shown. It is in every way a very desirable variety, in which, among other distinguishing features, the leaves have more of the peltate character of B. socotrana than have the other forms of Gloire de Lorraine.—K.

Physianthus albens.—This climbing asclepiad, a native of Buenos Ayres, is a decidedly free-flowering plant for the greenhouse, while in the favoured parts of the West of England it will grow out of doors. It is of quick growth, and a ligneous nature, the slender stems being clothed with light green leaves of a firm texture, and more or less cordate in shape. The flowers are freely borne in the axils of the leaves, and creamy-white. Fruits are occasionally produced, and, when present, they at once attract attention by reason of their unusual appearance. They are oval in shape, nearly as large as one's fist, and contain a quantity of seeds, with the silky appendages common to the order to which this physianthus belongs. Besides the name at the head of this note, it is also known as Arauja albens and Arauja sericifera.—W.

CLASSIFICATION OF SWEET PEAS.

The Floral Committee of the National Sweet Pea Society presents, in the "Sweet Pea Annual," the following as an up-to-date selection of varieties, placed in alphabetical order. * Indicates a grandiflora variety, all others are waved:

Bicolor—
Arthur Unwin
Colleen (A.M., R.H.S., 1909)
Mrs. Andrew Ireland (F.C.C., 1908)
Mrs. Cuthbertson (A.M., R.H.S., 1912)
Blue—
Flora Norton Spencer
*Lord Nelson (A.M., 1907)
Mrs. G. Charles
Blush—
Mrs. Hardcastle Sykes (A.M., 1905)
Princess Victoria (A.M., R.H.S., 1907)
Carmine—
John Ingman (F.C.C., 1904)
Cerise—
Cherry Ripe (A.M., 1910)
Decorator (A.M., 1912).
Cream, Buff, and Ivory—
Clara Curtis (F.C.C., 1909)
Isobel Malcolm
Paradise Ivory (A.M., 1908)
Cream-Pink (Pale)—
Gladys Burt
Lady Miller (A.M.,1912)
Mrs. H. Dickson (A.M., 1910)
Mrs. Routzahn
Cream-Pink (Deep)—
Constance Oliver (A.M., 1908)
Doris Usher (A.M., R.H.S., 1909)
Mrs. R. Hallam
Crimson—
King Edward Spencer
Maud Holmes
Sunproof Crimson (A.M., 1909)
Fancy—
Afterglow
Charles Foster (A.M., 1909)
Prince George
Lavender—
Florence Nightingale
Lavender George Herbert (Dobbie's)
Masterpiece (A.M.,1910)
R. F. Felton (A.M., 1912)
True Lavender
Lilac—
Agricola (A.M., 1912)
Magenta—
Menie Christie
Marbled and Watered—
*Helen Pierce (F.C.C., 1907)
May Campbell (A.M., 1911)
Maroon—
Black Knight Spencer
Nubian
Tom Bolton (A.M., 1906)
Maroon Purple—
Arthur Green (A.M., 1910)
Mrs. J. M. Gerhold
Maroon Red—
Brunette (A.M., R.H.S., 1912)
Red Chief
Mauve (Dark)—
Helio-Paradise
Queen of Norway (A.M. 1906)
Tennant Spencer
Wenvoe Castle
Mauve (Pale)—
Improved Bertrand Deal (A.M., 1912)
Mauve Queen (A.M.,1911)
Mrs. R. H. Carrad
Winsome
Orange-Pink—
Edrom Beauty (A.M., 1909)
Helen Grosvenor
Helen Lewis (F.C.C. and S.M., 1905)
Orange-Scarlet—
Dazzler (A.M., 1909)
Edna Unwin (A.M., R.H.S., 1909)
Thomas Stevenson (F.C.C., 1911)
Picotee Edged (Cream Ground)—
Evelyn Hemus (A.M., R.H.S., 1907)
Mrs. C. W. Breadmore
Picotee Edged (White Ground)—
Elsie Herbert (A.M.,1906)
Marchioness of Tweeddale
Mrs. Townsend
Pink (Deep)—
Countess Spencer (F.C.C., 1901)
Hercules
Pink (Pale)—
Elfrida Pearson (A.M., R.H.S., 1910)
Rose—
Marie Corelli
Marjorie Willis
Rosabelle
Salmon Shades—
Barbara (F.C.C., 1911)
Earl Spencer (A.M., R.H.S., 1910)
Melba (A.M., R.H.S., 1912)
Stirling Stent (F.C.C. and S.M., 1910)
Scarlet—
George Stark (F.C.C. and S.M., 1908)
Red Star (A.M., 1911)
Scarlet Emperor
Striped and Flaked (Purple and Blue)—
Loyalty
Suffragette
Striped and Flaked (Chocolate on Grey Ground)—
Senator Spencer
W. R. Beaver
Striped and Flaked (Red and Rose)—
America Spencer
Aurora Spencer
Mrs. W. J. Unwin (A.M., 1909)
White—
*Dorothy Eckford (F.C.C., 1902)
Etta Dyke (A.M., 1906)
Nora Unwin (A.M., 1907)

CHRYSANTHEMUM MAUD JEFFERIES.

I was much interested in the illustration of a model pot-grown chrysanthemum, Maud Jefferies (or Mrs. Swinburne?) in the GARDENERS' MAGAZINE of December 14.

I have grown these varieties several years, and still continue to do so, as Maud Jefferies and Mrs. Swinburne are two of the best white chrysanthemums we have. I have always found Maud Jefferies a good dwarf pot plant, either for large blooms or grown in the bush form. Mrs. Swinburne is a much taller variety, and does not break so freely as Maud Jefferies, and is not at all suitable for the form of plant shown. Mrs. Swinburne is so easily distinguished by its foliage. I should say by the appearance of the plant illustrated that it is Maud Jefferies.

W. DANIELS.

The Gardens, The Warren, Cromer.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The first meeting of the New Year was fairly well attended, but there was nothing like a crowd of people present at the Royal Horticultural Hall on January 7. Orchids were very much in evidence, and among these the cypripediums and lælias were abundantly represented. Greenhouse-flowering plants, a few alpines, and fine exhibits of fruits and vegetables completed the chief attractions of the day. Mr. Raffil's fine collection of large photographs, representing plants and scenes at Kew, formed a very distinct and pleasing feature of the meeting, and he was, deservedly, awarded a silver-gilt Flora Medal; there were several hundred photographs, representing a wide range of subjects, but orchids and flowering trees and shrubs were most largely shown.

FLORAL COMMITTEE.

Cyclamens were grandly shown by Messrs. Sutton and Sons, Reading, this firm putting up large semi-circular blocks of their fine varieties, Vulcan, Giant Rose Pink, Giant Salmon Pink, Giant White, and Salmon Scarlet, the latter an excellent variety that lights up finely under artificial light. Needless to say, every plant was perfectly grown and smothered with graceful blooms. Messrs. Wm. Cutbush and Sons, Highgate, presented a bright exhibit, composed of carnations—Mrs. L. Mackinnon was shown grandly—forced flowering shrubs in great variety, Iris histrioides major, I. Danfordiæ, I. Tauri, and other delightful early flowers.

Messrs. Jas. Veitch and Sons, Chelsea, filled a long table with bright greenhouse-flowering plants, and their display included Primula malacoides, Indian azaleas, Senecio grandifolius, winter-flowering begonias, the blue Coleus thyrsoideus, fragrant freesias, the White Eupatorium vernale, and the lavender-hued Erlangea tomentosa. Lindenbergia grandiflora, with yellow flowers, was a somewhat uncommon plant in this group. A bright exhibit of cut pelargoniums, from Messrs. H. Cannell and Sons, Swanley, showed how, out in the country, these handsome flowers can be of great service during the winter. Such varieties as Duke of Bedford, George Coats, New York, King Victor, Cymric, Prince of Orange, Kingswood, and Blenheim were particularly effective.

Ferns and selaginellas, from Messrs. H. B. May and Sons, Edmonton, provided an interesting exhibit. Gymnogramma Cordreyi, Asplenium marginatum, Polypodium Mayi cristatum, and Adiantum Farleyense gloriosum were a few of the leading kinds. Agave filifera Leopoldi, with narrow green leaves and whitish marginal threads, was well shown by Mr. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill. This is an interesting and elegant greenhouse plant. Messrs. Allwood Brothers, Haywards Heath, had a small exhibit of perpetual-flowering carnations, and chief among their varieties were the new Mary Allwood—which we have illustrated—Rosette, Fairmount, and a few of the older sorts.

Single varieties of camellias, as shown by Messrs. Wm. Paul and Sons, were very attractive, the flowers being lighter and less formal than the double ones. Minerva, Snowflake, Waltham Glory, Vesta, Adelina Patti, and Tricolor were the varieties on view, and every one is well worthy of cultivation by those who have accommodation for camellias. Isoloma hirsuta, with its pendant orange-red flowers and abundant foliage, was shown in good form by Mr. L. R. Russell Richmond, who also contributed Indian azaleas.

Messrs. R. Gill and Sons, Falmouth, showed how kind is the climate of South Cornwall by setting up handsome trusses of Rhododendron arboreum, R. barbatum, and R. argenteum, with fruiting branches of Benthami fragifera, and a little colony of the new Primula Winteri, with its lilac-coloured flowers. Hellebores, saxifrages, Potentilla Miss Willmott, primulas in variety, violas, etc., were all well grown by Messrs. T. S. Ware, Lim., Feltham.

A large exhibit from Messrs. Whitelegge and Page, Chislehurst, showed that this firm has a fine strain of the popular Primula obconica, the flowers being large and the colours varied, some being of a quite blue shade. Messrs. Pipers, Bayswater, put up a good strain of Primula obconica, with a backing of evergreen shrubs, chiefly dwarf conifers. Mr. G. Reuthe, Keston, also showed trees, berberis, saxifrages, charming little irises, snowdrops, hardy cyclamens, hellebores, etc.

Hardy heaths, early primulas, pigmy shrubs, daphnes, and irises were grouped among rockwork by Messrs. J. Cheal and Sons, Crawley. This firm also contributed models of garden furniture, bridges, gates, etc., and a model to scale of Messrs. Cheal's pergola and formal garden as exhibited by them at the recent Royal International Horticultural Exhibition at Chelsea. Mr. Clarence Elliott, Six Hills, Stevenage, displayed alpines and pigmy shrubs suitable for the rock garden, and a little group of Saxifraga Burseriana major was very pretty. Messrs. J. Peed and Sons, Norwood, were other exhibitors of alpines.

Perpetual carnations of excellent size and fine colour, contributed by Mr. H. Burnett, Guernsey, made up a very bright display. The yellow-ground varieties, Sunstar and Mandarin, were conspicuous, with Scarlet Glow, Mrs. C. F. Raphael, St. Nicholas, Marmion, and numerous beautiful pink and white varieties. Carnations were well displayed by Messrs. Stuart Low and Co., Enfield, and, besides the popular sorts, this firm submitted Exquisite, a new rose-flaked variety; Cinnabar, a cinnabar-red variety, sweetly scented; Satin Robe, rose-pink; Benora, red-flaked; and Fairmount, deep bluish-heliotrope. Messrs. W. Wells and Co., Merstham, were exhibitors of carnations, and showed bright clear flowers of Bonfire, Gloriosa, R. F. Felton, Mrs. H. Burnett, Dorothy Gordon, and the new American variety named Northport, a rich cerise, free-flowering variety. Mr. C. Engelmann had a small but very bright exhibit of carnations, and his bunches of Elektra, Rosette, Sunstar, and Harlequin were especially bright.

ORCHID COMMITTEE.

The members of this committee turned up in strong force, and had a very large amount of work to do, about thirty novelties and numerous groups coming under their consideration.

Mr. Page, gardener to G. F. Moore, Esq., Chardwar, Bourton-on-the-Water, exhibited a grand gold-medal lot of cypripediums, splendid plants, carrying a famous lot of fine blooms. Varieties of C. insigne and C. Leeanum were plentiful, and indeed formed the bulk of the collection, but there were C. Thompsoni, C. Hera Euryades, C. Argo-Fairrieanum, C. veronicus, C. Niobe superbum, C. Maudæ, C. Bridgei magnificum, C. Wm. Lloyd magnificum, C. Venus, C. Prospero, C. triumphans, and many other good things. In the group of orchids from Messrs. James Veitch and Sons, Chelsea, were a number of excellent cypripediums, notably C. Milo superbum, C. Golden Glory, C. Hera Euryades, C. Idina var. Portia, very fine; C. Actaeus Langleyense, and C. Little Gem.

From Baron Bruno Schroder's collection at The Dell, Egham, Mr. Shill brought up a very beautiful lot of well-grown plants of varieties of Lælia anceps. The spikes and blooms were of excellent size, and the group was greatly admired. Of course, all the best varieties were on view, and we made special note of L. a. Ballentinianum, L. a. Schroderæ, L. a. Crawshayanum, L. a. alba, L. a. Amesiæ, L. a. Sanderiana, etc. A fine form of Odontoglossum Pescatorei, with pale shading and markings instead of the usual bright purple spots, was exhibited with the lælias, and concerning it a curious point arose; the plant was awarded a F.C.C. some years ago, but as a flower was not available for the artist to paint for the R.H.S. collection of certified orchids, the award lapsed. On this occasion the Committee confirmed the old award for the old date, on condition that flowers were provided for a painting.

Messrs. Charlesworth and Co., Haywards Heath, presented a graceful contribution of orchids; their spikes of Odontoglossum Phœbe, O. P. magnificum, O. Gladys, O. Phædra, and O. ardentissimum were very beautiful. Under those we noted such good things as Lælio-cattleya Bella alba, carrying a spike of six grand flowers; L.-c. Golden Oriole, L.-c. Ariel, and L.-c. Sunray, all orange and yellow-tinted varieties; Odontoglossum Ceres, Odontioda Bohnhofiæ, and the curious Adioda St. Fuscien, Heaton variety, a cross between Cochlioda Noezliana and Ada aurantiana. Mr. O. Hayles, gardener to Sir Charles Haddon, Rossway, Berkhampstead, set up seven specimens of Cypripedium insigne crowded with flowers.

Miltonia Blenana gloriosa was very fine in the collection from Messrs. Sander and Sons, St. Albans, and Lælio-cattleya William Gott in the same group carried five beautiful salmon and purple flowers. Other notable plants were Brasso-cattleya Vesta, Cycnoches Cooperi, a very curious flower; and Lælio-cattleya Pauline. In the exhibit from Messrs. Stuart Low and Co., Enfield, the outstanding features were Phalænopsis amabile, P. Schilleriana, Angræcum eburneum, Lælia anceps, Oncidium tigrinum, Dendrobium Wardianum, Ansellia africana, and Brasso-cattleya Maronæ.

Mr. H. Day, gardener to H. S. Goodson, Esq., Fairlawn, Putney, had a goodly group of orchids, and staged Cymbidium Traeyanum, a great variety of odontoglossums, including O. Hebe, one of the Rossi crosses, a few odontiodas, with cypripediums and miltonias, all pleasingly arranged with ferns and green moss. Cypripediums were submitted by Mr. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill, together with Odontoglossum Loochristiense, Lælia anceps Sanderiana, and the interesting Eulophia virescens with a long spike of green flowers. The deep rose-coloured Calanthe Vulcan, with one or two well-grown odontoglossums, were exhibited by Mr. A. Metcalfe, gardener to Lady Wernher, Luton Hoo, Luton.

From Cheltenham, Messrs. J. Cypher and Sons brought up various calanthes, several of the finer white-flowered forms of Lælia anceps, the rare and beautiful little Ancistrochilus Rothschildiana, and fine examples of Cypripedium Bridgei, C. Euryades Sander's var., C. Actæus Sybil, C. aureum Surprise, and the free-flowering C. Charlesworthianum Cypher's var. Messrs. A. and J. McBean, Cooksbridge, exhibited a large number of very beautiful odontoglossum spikes, and a few good cypripediums, odontiodas, and miltonias. Mr. E. H. Davidson, Orchid Dene, Twyford, showed large spikes of Oncidium crispum, a few good cypripediums, and first-rate odontoglossums.

Several exhibitors brought new orchids. Lieut.-Colonel Sir George Holford had a very pretty cypripedium named Corsair, obtained by crossing C. niobe and C. nitens. Mr. F. M. Ogilvie gained an A.M. for his large and bold Cypripedium Amazon. Interesting and pretty was Odontonia Firmini, shown by M. Firmin Lambeau, of Brussels; this is the result of crossing Odontoglossum crispum with Miltonia vexillaria. The flowers are flattish, and, with the growth, betray the influence of the Miltonia parent; but the white flower, yellow crest, pink-flushed lip, and modified form of the bloom indicate the odontoglossum parent. Mr. de Barri Crawshay showed Odontoglossum Vulcan in fine form, and Mr. Roebling sent, all the way from Trenton, New Jersey, U.S.A., a flowering plant of Lælia anceps Roeblingiana, with curiously-striped petals, and gained an A.M. for it. Cypripedium Iona, from the Duke

of Marlborough's collection, a very neat purple and white flower. also secured an A.M.

FRUIT AND VEGETABLE COMMITTEE.

Messrs. Jas. Veitch and Sons, Chelsea, showed apples in great style, and filled the side of one long table with splendid fruits, set up on dishes or baskets. About a hundred and five varieties of apples were represented, and not a faulty or even a second-rate fruit could be found among the thousands exhibited. A few varieties of especial merit or attractiveness were Bismarck, Bramley's Seedling, Emperor Alexander, Blenheim Pippin, Alfriston, Newton Wonder, Adams' Pearmain (extra good), Sandringham, Lemon Pippin, Golden Noble, Lord Derby, Hector Macdonald, Northern Greening, Reinette du Canada, Blue Pearmain (a very attractive apple), Ribston Pippin, Washington, Baldwin, Cox's Orange Pippin, and Mabbott's Pearmain.

Apples in splendid condition and great variety were staged by Messrs. W. Seabrook and Sons, Chelmsford. A few of the finer examples were Lord Derby, Blenheim Orange, Claygate Pearmain, Cox's Orange Pippin, The Queen, Lane's Prince Albert, Bismarck, King of the Pippins, and Newton Wonder. Mr. A. G. Gentle, gardener to Mrs. Denison, Little Gaddesden, Berkhamsted, is a famous vegetable grower, and on this occasion gave further evidence of his skill by showing a large collection of finely-grown carrots, all the roots, long or short, being clean and perfect, and fine alike in form and colour.

The early spring vegetables, so finely displayed by Messrs. Sutton and Sons, Reading, included New Year savoys, kohl rabi, Early Sprouting broccoli, Batavian endive, chicory, Sutton's Hearting Couve Tronchouda, Superb Early White broccoli, kale, celeriac, mushrooms, seakale, and carrots. Mr. W. E. Sands, Hillsborough, Ireland, submitted about five dozen dishes and baskets of potatoes. Most of the popular varieties were well represented, and of special interest were the baskets of Colleen, Vitality, International Gem, Shamrock, and the clean pebble-shaped Irish Gem that gained an A.M. last year.

AWARDS.

Award of Merit.—To Messrs. Jas. Veitch and Sons, Chelsea, for Lindenbergia grandiflora; to Lælia anceps Roeblingiana, from Mr. E. G. Roebling, Trenton, New Jersey, U.S.A.; to Odontonia Firmini, from M. Firmin Lambeau, Brussels; to Cypripedium Amazon, from F. Menteith Ogilvie, Esq., The Shrubbery, Oxford; to Cypripedium Iona, from the Duke of Marlborough, Blenheim; to Cypripedium Alcimeda, from Messrs. Charlesworth and Co., Hayward's Heath; and to Odontoglossum George Day, from H. S. Goodson, Esq. (gardener, Mr. G. Day), Putney.

MEDALS.

Gold.—To Messrs. Jas. Veitch and Sons, Chelsea, for apples; to G. F. Moore, Esq. (gardener, Mr. Page), for cypripediums.

Silver-gilt Flora.—To Messrs. Sutton and Sons, Reading, for cyclamen; to Baron Bruno Schroder (gardener, Mr. Shill), Egham, for group of Lælia anceps.

Silver-gilt Banksian.—To H. S. Goodson Esq., Putney, for orchids.

Silver Flora.—To Mr. H. Burnett, Guernsey, for carnations; to Messrs. H. B. May and Sons, Edmonton, for ferns; to Mr. C. P. Raffil, Kew, for photographs of plants; to Messrs. Jas. Veitch and Sons, Chelsea, for greenhouse plants.

Silver Knightian.—To Messrs. W. Seabrook and Sons Chelmsford, for apples; to Mr. W. Sands, Hilsborough, for potatoes; to Messrs. Sutton and Sons, Reading, for early spring vegetables.

Silver Banksian.—To Messrs. J. Veitch and Sons, Chelsea, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. Jas. Cypher and Sons, Cheltenham, for orchids; to Mr. E. H. Davidson, Twyford, for orchids; to Messrs. J. and A. McBean, Cooksbridge, for orchids; to Messrs. W. Cutbush and Sons, Highgate, for carnations, etc.; to Mr. C. Engelmann, Saffron Walden, for carnations; to Messrs. R. Gill and Sons, Falmouth, for rhododendrons, etc.; to Messrs. S. Low and Co., Enfield, for carnations; to Messrs. Wm. Paul and Son, Waltham Cross, for camellias; to Messrs. Whitelegge and Page, Chislehurst, for Primula obconica; to Messrs. Pipers, Bayswater, for primulas and shrubs; to Mr. G. Reuthe, Keston, for hardy plants; to Mr. Gentle, gardener to Mrs. Denison, Little Gaddesden, for a collection of carrots; to Mr. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill, for orchids.

Dumfries Gardeners' Reunion.

On the evening of December 20 the Dumfries gardeners held their third annual reunion, this taking the form of a dinner in the Queensbury Hotel. Mr. J. Hutchison, Terregles Gardens, occupied the chair, and the croupiers were Mr. M'Donald, Cargen Gardens, and Mr. Pritchard, The Grove Gardens. There were upwards of sixty gardeners present, with members of the nursery trade from Dumfries and larger Scottish towns. Mr. Taylor, The Gardens, Brocklehurst, again fulfilled the secretarial duties in a most satisfactory manner, and the function was a brilliant success. A number of songs and toasts maintained the interest of the evening after dinner. After the usual loyal and patriotic toasts, that of "The Town and Trade" was given by Mr. Brown, Portrack Gardens, and responded to by Mr. David Barr, of Messrs. Barr and Hunter (Jas. Service and Sons). The leading toast, that of "The Gardeners," was ably proposed by Mr. Chalmers, and suitably replied to by Mr. Pritchard. That of "The Seed and Nursery Trade" was placed in the hands of Mr. Riddick, Ellangowan Gardens, and responded to by Mr. Hunter, of Messrs. Barr and Hunter. The services of the chairman and secretary were also recognised in a similar way. As a result of this and former reunions, it is intended to form a local gardeners' association.

Acacia ovata.—After the two or three Australian acacias (of which A. platyptera is the best) that flower during the autumn and early winter months, one of the first to bloom in the New Year is Acacia ovata, or obliqua as it is sometimes called. This is of a neat, twiggy habit of growth, the shoots being plentifully furnished with small ovate leaves of a deep green tint. The flowers, borne in little balls, are of a rich golden hue. This species is admirably adapted for growing as small plants.—T.

Impatiens Herzogi.—Within the last decade or so we have had a great number of tender members of the balsam family introduced into this country, one of the most recent being Impatiens Herzogi. It forms a compact-growing plant with succulent stems, somewhat after the manner of the older Impatiens Hawkeri, but the flat flowers, which are larger than in most of the others, are of a salmon-orange hue. During the dull weather we often experience in the autumn it is very bright and pleasing.—S. W.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the PUBLISHING MANAGER, 148-9, Aldersgate Street, London, E.C., who will give the matter immediate attention.

ABSORPTION OF COPPER FUNGICIDES BY POTATOES.

In connection with experiments on wart disease of potatoes conducted in Lancashire in 1910, different plots were, according to the "Journal" of the Board of Agriculture, treated with Strawsonite and copper sulphate, each at the rate of 75lb. per acre. The materials, in the form of a powder, were applied to the plots at the time the potatoes were planted, and as it seemed possible that some of the copper might be absorbed by the crop, samples of the tubers from each plot, and also from an adjoining piece of ground left untreated, were analysed at the Government Laboratory. The tubers selected for examination were thoroughly washed and scrubbed to remove all earthy matter, and were then peeled as for culinary purposes, all eyes and bruises being removed and included in the peel. The peel and the potato substance were examined separately for copper.

The amounts of copper found in the peel and in the substance of the tubers respectively are shown in the following table:—

	Peel. Grains.	Substance. Grains.
Strawsonite Plot.		
Grains of copper per lb. of undried material	0.217	0.021
Grains of copper per lb. of dried material	1.44	0.10
Copper Sulphate Plot.		
Grains of copper per lb. of undried material	0.028	0.014
Grains of copper per lb. of dried material	0.16	0.08
Untreated Plot.		
Grains of copper per lb. of undried material	0.021	0.014
Grains of copper per lb. of dried material	0.12	0.07

The figures show that the quantity of copper was somewhat greater in the peel than in the potato substance There was practically no difference between the quantity in the tubers on the copper sulphate plot and that in the tubers on the untreated plot. The most noteworthy feature was the quantity of copper in the peel of the tubers from the plot treated with Strawsonite.

In order to check this somewhat striking result, small plots treated similarly to those previously described were planted at Kew in 1912, and samples of the crop of tubers from the different plots were examined at the Government Laboratory.

The results are shown in the following table:—

	Peel. Grains.	Substance. Grains.
Strawsonite Plot.		
Grains of copper per lb. of undried material	0.0144	0.0085
Grains of copper per lb. of dried material	0.088	0.045
Copper Sulphate Plot.		
Grains of copper per lb. of undried material	0.0168	0.0098
Grains of copper per lb. of dried material	0.094	0.051

In this case the tubers from the Strawsonite plot contained similar amounts of copper to those from the copper sulphate plot; and the results obtained two years ago are therefore not confirmed. A comparison of the results obtained in the two years shows that the samples examined in 1912 did not contain more copper than was found to be present in 1910 in tubers which had been grown in soil untreated with copper fungicides.

Early-flowered Indian Azaleas.—Where these azaleas are required to be had in flower early a note should be made of those varieties which naturally flower much earlier than the others. Very early are the well-known white Deutsche Perle, the rose-pink Madame Petrick, and J. B. Varonne, whose deep salmon-rose flowers are margined with white. A moderate increase in temperature is sufficient to accelerate the development of the flowers.—K.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

NATIONAL ROSE SOCIETY'S SPRING SHOW.—Rosarian: In the report of the annual meeting of the National Rose Society, which you published about a month since, it was stated that the society would hold a spring exhibition at the Royal Horticultural Hall on May Day. I have recently heard on what appears to be very good authority, that there is a probability of the date of the exhibition being altered. I shall be obliged by your informing me whether any change has been made, and, if so, by your giving me the date.—A suggestion that a slight change in the date should be made was, we understand, brought before the Council at its meeting on Tuesday, when it was thought advisable to allow the original date to stand.

SOIL INOCULATION.—M. H. K., Hants: A few years since much was written about the possibility of increasing the fertility of soils by inoculation with bacteria adapted to the requirements of the several leguminous plants, and I believe various preparations were on sale. It has occurred to me that I might make a few experiments in soil inoculation during the year, and I should like to know whether the results have justified expectations, and, if so, whether the preparations of inoculation are still obtainable.—The results of the experiments that have been made in the inoculation of soil with bacteria during the past few years have not realised anticipations, and bacterial preparations are not, so far as we are aware, now obtainable. With reference to this matter, Dr. E. J. Russell, one of the highest authorities on cultivated soils, writes in his book on "Soil Conditions and Plant Growth": "Where a new leguminous crop is being grown for the first time it may be necessary to introduce the appropriate organism, as has been successfully done in Canada by Harrison and Barlow, and on the North German moors by Hiltner. But, in general, these inoculations have not proved useful, and they have never come into farming practice; the high hopes sometimes entertained that the whole problem of nitrogenous manuring — the most costly item in the farmer's fertiliser bill— might reduce itself to bacterial inoculation have never been realised. The problem is extraordinarily fascinating, and never fails to arouse popular interest, but it is elusive and treacherous, and has raised more false hopes, and led to more disappointments than any other in our subject."

DEFINITION OF AMATEUR. — R. W., Devon: I am the chairman of the committee of one of the many horticultural societies in the West of England, and, as difficulties are constantly arising with regard to the status of an amateur, I shall be greatly obliged by your giving such advice as will enable the society to surmount such difficulties. As you will readily understand, constant quibblings about amateurs at flower shows is not only unpleasant, but it has a hurtful effect upon societies.—We willingly comply with your request for information on the status of amateurs as competitors at flower shows, for no one is more familiar with the discussions that are constantly taking place than ourselves. It is not, however, so difficult to avoid unpleasantness in connection with this matter as is assumed to be the case. In the first place, it is necessary to accept the definition as given in a really good dictionary, but this few of those who are associated with the management of horticultural societies are willing to do. Taking down the first dictionary that comes to hand, we find an amateur defined as "One who follows any science, art, or occupation, not from pecuniary motives, but from a love for it, and who, as a rule, is not so proficient in it as if he had to depend upon it for a livelihood." If you adopt such definition, and then for competitive purposes classify the members, other than those engaged in business connected with gardening, into groups according to the facilities they have all difficulties will disappear. You might have four sections, namely, amateurs with an unlimited gardening staff, amateurs who have one gardener, amateurs who have occasional help, and those who do the whole of the work of the garden themselves. The Royal Horticultural Society have adopted an arrangement based on these lines, and recommend it in their "Code of Judging," which we advise you to obtain.

ROCK PLANTS.—W. K. F., Norfolk: I intend forming in my garden a rockery, not over-elaborate, but sufficient to enable me to successfully cultivate a representative collection of alpine plants, and I am anxious to obtain a book that is moderate in price, and will give me the information necessary to enable me to build and plant a rockery of the character indicated.—"Rock Gardens and Alpine Plants," by E. H. Jenkins, and published by Messrs. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C. (price 2s. 9d., post free), contains all the information you require, and is so clearly and pleasantly written that you will have no difficulty in following the author's directions.

OLD RAMBLING ROSES. — Amateur: Being interested in roses of rambling and scandent habit, I have been looking up the history of some of the climbing roses we have still in gardens at the present time which were raised early in the nineteenth century. I have not been able to ascertain the names of the raisers or the years of introduction of Bennett's Seedling, Félicité Perpetué, Princess Marie, and William's Evergreen. Probably you can assist me in the matter.—Bennett's Seedling was raised by Bennett, and introduced to cultivation in 1840, Félicité Perpétue was raised by Jacques and introduced in 1828, Princess Marie was raised by Jacques and introduced in 1829, and William's Evergreen was raised by Williams and introduced in 1850.

ORCHIDS.—F. B., Sussex: During the past few years I have been much interested in the many beautiful orchids that have been contributed to the meetings of the Royal Horticultural Society, and have had under consideration the question of commencing their cultivation. I have a rather large garden, which is managed by a gardener, who has two men under him. As I have ample leisure, my idea is to build two or three houses, and superintend the orchids myself with the help of a young man who has had some experience in the cultivation of these plants. I am prepared to devote the necessary time to the collection, and to carefully study the requirements of the several kinds. Do you think I should be likely to succeed?—There is no good reason why you should not succeed with a representative collection, and derive much pleasure from it. The culture of orchids is not difficult once a few of the more important details have been mastered, that is, supposing the collection is of kinds that possess a fairly robust constitution. You will at first meet with failures, but in time will know the peculiarities of the several kinds in growth and requirements. It must be remembered that diversity of treatment is necessary simply because the orchid family is widely distributed, some kinds growing on mountain tops, others in the hot humid valleys of the tropics. If the tropical kinds are to be included there must be a warm or East Indian house, and a house in which a cooler temperature is maintained for the masdevallias, odontoglossums, etc. We should advise you to have three houses, or one long house or range divided into three compartments: the first for the tropical kinds, the second for those that will thrive in the intermediate temperature, and the third for the cool kinds, of which the odontoglossums may be cited as examples.

PULVERISED SHEEP'S MANURE.—J. B., Derby: We are not acquainted with a manure sold under this name, and are therefore unable to say where it can be obtained.

RHODODENDRON NOBLEANUM.—S. S., Dorset: In visiting an old garden the other day in the south-west of England, I saw a large specimen rhododendron in full bloom and bearing rich rose-red flowers. My friend's gardener was away at the time, and consequently I was unable to ascertain the name. The rhododendron was new to me, but, judging from the size of the specimen, it must have been long in cultivation. I should like to add a few plants to my garden, and probably you will be able to tell me the name.—The rhododendron is probably Nobleanum, a hybrid raised many years ago from a cross effected between R. arboreum and R. caucasicum, and possesses much beauty. This year the flowers have escaped injury from frost, and well-developed specimens have been highly attractive, but it very often happens that the flowers are seriously injured by a frost, a fact you will do well to bear in mind. If you have a large garden there will be no objection to adding Nobleanum to your collection of shrubs, but otherwise devote the space to one of the late-flowering varieties of which there are now so many that are of great excellence.

NAMES OF PLANTS.

W. S. F., Lancashire.—Your plant is the variety of Epiphyllum truncatum known as violaceum.

F. T., Torquay.—The fern of which you send us a splendidly-developed frond is Woodwardia radicans.

R. H., Herts.—1, Tillandsia hieroglyphica; 2, T. Lindeni tricolor; 3, Bilbergia vittata; 4, Tillandsia tesselata.

W. B., Surrey.—1, Panicum variegatum; 2, Leea amabilis splendens; 3, Odontoglossum crispum; 4, Zygopetalum crinitum.

W. T., Yorkshire.—1, Begonia Winter Cheer; 2, Julius; 3, Ideala. The flowers had suffered much in transmission through the post, owing to their having been loosely packed.

Spraying

And Limewashing Machines

In every garden and on every estate one of these 'Four Oaks' machines are indispensable.

Will spray the Fruit Trees, Limewash the Stables, Kennels, Outbuildings, &c., in a fraction of the time taken by brushes.

Complete Catalogues of Spraying and Limewashing Machines & Syringes free on application to Sole Manfactrs.: The

'Four Oaks' Limewashing Machine, "Royal Pattern" **£3 18s. 6d.**

FOUR OAKS SPRAYING MACHINE CO., No. 30, Sutton Coldfield, Birmingham.

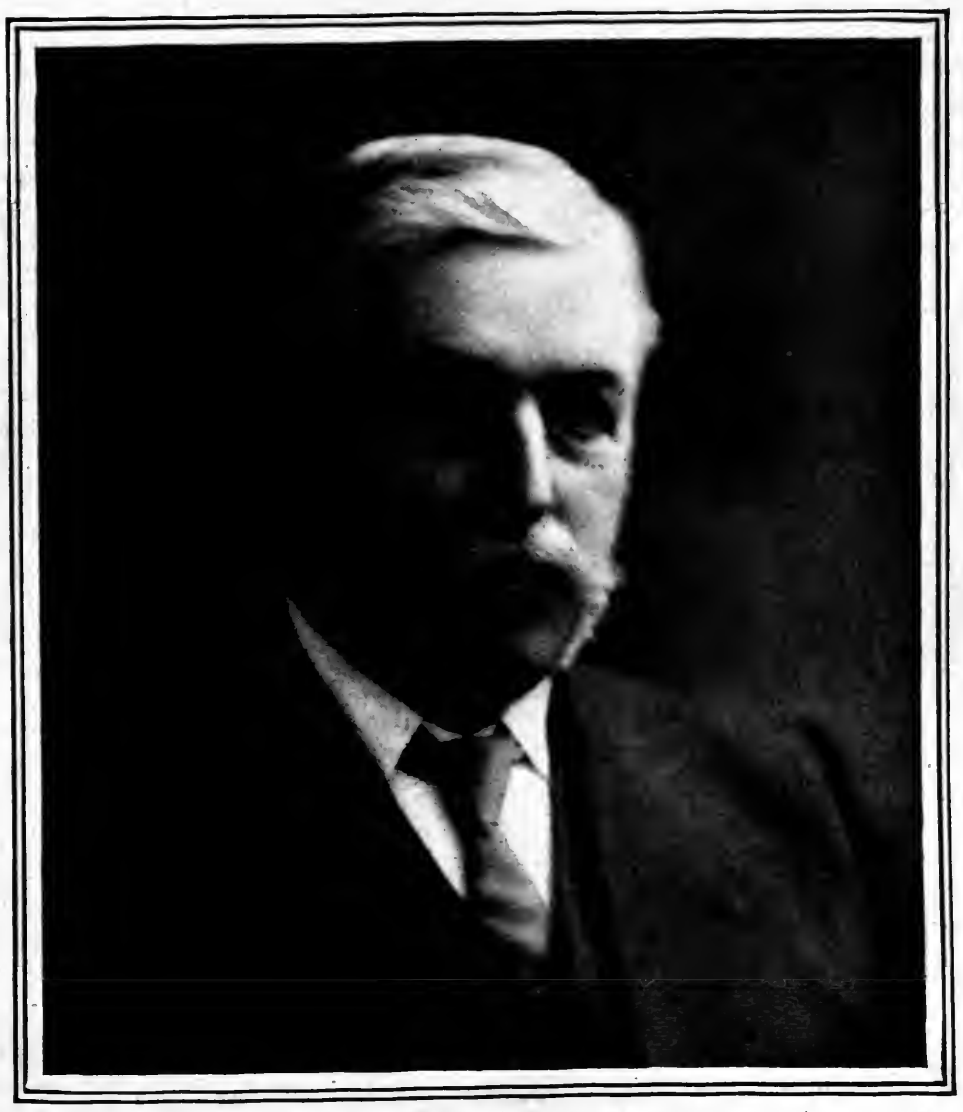
VOL LVI.—No. 3,090. SATURDAY, JANUARY 18, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Vegetable Crops.

As a consequence of the moist conditions that obtained during the greater part of the summer of the past year, and the comparatively high temperature experienced during the autumn and the early part of the winter through which we are now passing, vegetables of most kinds are abundant and cheap. We should, indeed, have to go back several years to find the kitchen garden so well stocked, and the markets so liberally supplied as they are at the present time. It is not at all probable that this abundance will divert the attention of either the gardener or the market grower, with some years' experience, from the necessity of making active preparations for successional crops, or of overlooking the possibility of weather of sufficient severity to do considerable damage to the green crops that now present so luxuriant an appearance in the majority of gardens. But the young gardener and the amateur who has only recently undertaken the responsibilities involved in the maintenance of a regular supply of the products of the kitchen garden may not fully appreciate the importance this season of being especially alert in all that relates to this department and its management. Hence the necessity for a reference to some of the points that should be constantly kept in mind at this season. The robust appearance of the green crops on which the table will have to depend more or less for its supplies for some time will give rise to considerable apprehension in the mind of experienced cultivators. They will know that this exceptional development is due to the large amount of moisture in the soil, and the high temperature which was experienced until quite the end of last year. Instead of the plants passing into a resting state with the close of the autumn they continued in an active state of growth until within a very recent period, with the result that the stems, leaf-stalks, and leaves are so succulent that weather of even moderate severity would in many gardens, where the soil is cold and retentive of moisture, seriously injure them. Broccolis, which possess so much value for the supply of the table at the present time, are the first to suffer from severe frosts, following closely upon periods of wet and abnormally warm weather, and fortunate are those who have acted upon the advice given in these pages, and heeled over the plants with their heads to the north. This practice is very old, but the results of its adoption fully justify its inclusion in the routine of kitchen gardens that are managed in accordance with the more advanced modern methods. When the plants are so



MR. GEORGE HAIGH.

manipulated that they are laid down more or less horizontally with the roots still in the ground, the central leaves remain close together, and thereby protect the heart instead of opening out, as when the plants are standing erect, and fully exposing it to the frost. In addition, the large leaves of one plant assist in protecting its neighbour on the north side, and, if desired, protecting materials can be more readily applied. Whatever may be the position of broccolis, and especially the earlier kinds, they should, as far as practicable, have some protection as soon as severe weather is anticipated, and in some parts of the country the weather has been sufficiently severe to justify the immediate resort to protective materials. Not only should broccolis receive protection, but, as far as practicable, all crops that are likely under existing conditions to be injured by severe frosts. It may be that the frosts will not be of sufficient severity to do much damage, but it is not probable, and the wise cultivator will do all that is within his power to avert a "break" in the supplies towards the end of the winter, by utilising the pits or frames that may be available in the acceleration of vegetable crops. Some may, of course, be used in the production of such crops as will come along so rapidly as to be available for the table in a comparatively short time, and others be devoted to the raising of plants for transferring to warm borders immediately it can be done with safety. The value of pits and frames cannot well be over-estimated, more especially the portable kinds with span roofs, and this value is brought into strong relief in a season such as this. The methods by which these frames can be utilised in the production of early crops of vegetables are admirably described in the series of articles on this subject from the pen of Mr. F. Drew, which were commenced in our issue for the 4th inst., and to these we would direct the special attention of those who are in need of information on this important part of the gardening art. In many gardens where the soil is naturally unfavourable to the germination of seeds, it may this year be advantageous to raise some of the kinds intended for the earliest crops under glass, instead of sowing them in the open, in accordance with the usual practice, and plant them out later on. This procedure will involve additional labour, but it will be well repaid, for not only will the crops be somewhat accelerated, but the growth will be more satisfactory from the first, and in all probability the quality will be higher. To ensure a full measure of success in the case of such crops, the germination of the seeds or the growth of the young plants must not be assisted with artificial heat. There would be no harm in keeping the frames closed until the seedlings begin to make their appearance above the surface of the soil; but anything beyond this would be distinctly harmful, except a mat laid over the glass on a frosty night. The object of sowing under glass is not to obtain a growth stimulated by artificial conditions, but to provide the plants with a favourable root run

in their earliest stage, and shelter them from frosts and keen winds, which are so trying to tender plant life when growth is slow. It should also be remembered that the seed harvest of 1912 was unfavourable to the ripening of the seeds of some of the kinds, and that, as the stocks are rather short in consequence, orders for seeds should be given as early as possible to avoid disappointment. In all seasons it is advisable to purchase seeds early, that there may be no delay when the proper time arrives for sowing them. The importance of sowing seeds at the time when the soil and weather are alike favourable has so frequently been referred to in these pages that we need not do more now than merely mention it as a matter of special importance in the present season.

Mr. George Haigh, who for upwards of a quarter of a century has had the charge of the gardens of Highfield Wootton, the residence of Sir William H. Tate, has long been regarded as one of the leading gardeners in the great district of which Liverpool is the centre, and has fully justified the reputation he enjoys. Before coming to Highfield, Mr. Haigh had a thorough and varied training, and to this, combined with great natural ability, may be attributed the success he has achieved. Mr. Haigh commenced his gardening career at Escrick Park, near York, where he remained four years under Mr. Mitchell, who fully appreciated the importance of an intimate acquaintance with the cultivation of fruits and vegetables. From Escrick Park Mr. Haigh went to Aske Hall, Richmond, Yorkshire, to fill the position of foreman of the kitchen garden, and subsequently he occupied responsible positions in the gardens of Sudbourne Hall, Wickham Market, Suffolk; and Waddesdon Manor, Aylesbury, and remained in each of these gardens some years. On leaving Waddesdon Manor in 1887, Mr. Haigh was appointed head gardener to Sir W. H. Tate, Bart., whom he regards as the best and kindest of employers. During the past twenty years or so chrysanthemums have formed one of the special features of the Highfield Gardens, and during that period several challenge cups have been won for these fine autumn flowers. The two cups that are the most highly appreciated were won at Liverpool. One of these—the Liverpool Horticultural Association's Challenge Cup for forty-eight blooms, distinct—was won in four consecutive years, a feat of which even so successful a cultivator as Mr. Haigh might well feel proud. The varied and finely-grown collection of orchids constitutes another special feature with reference to which much might be written, but it must suffice to say that Lælia purpurata and Oncidium macranthum are grown with a degree of success that is quite exceptional.

Calanthe Flowers from Dybdale.—Mr. D. Burridge sends us from the Dybdale Gardens, Wellingborough, some spikes of Calanthe Veitchi in so high a state of development as to suggest cultural skill of the highest class. The spikes were about five feet in length, and the upper half of each was thickly set with large, richly-coloured flowers. In the letter accompanying the flowers Mr. Burridge writes, "I am pleased to be able to send you the enclosed spikes of calanthes, which are the result of carefully following the advice given in the pages of the GARDENERS' MAGAZINE from time to time. I first commenced the culture of calanthes in the spring of 1910, and should like to know what you think of them. They are a fair sample of the spikes we have. The plants are growing in five and six-inch pots, and most of the old pseudo-bulbs produced two new ones, and the largest of these are nine inches in circumference and nearly nine inches in height. I heartily wish you the compliments of the season, and am looking forward with interest to the many good things that I know you will provide for your readers."

"The Orchid Review," a monthly journal devoted to orchidology, enters, with its January issue, upon its twenty-first year. From the beginning it has been admirably edited by Mr. R. A. Rolfe, A.L.S., and who, entering Kew as a young gardener many years ago, now occupies a prominent position in the Herbarium, and is the recognised botanical expert on all orchid matters. The first issue of the twenty-first volume is larger than usual, and it contains a portrait of the Editor, numerous illustrations, and a brisk discussion on the ever-present question of orchid nomenclature. We tender our congratulations to Mr. Rolfe and those who assist him, and, as "The Orchid Review" is essentially a work of reference, we learn with pleasure that the formation of an index to the first twenty volumes is likely to appear before long.

Acacias at Cannes.—One of the most attractive features of Cannes early in the year is formed by the great breadths of acacia or mimosa trees, the flowers of which glow in the sun, and fill the air with their pleasant perfume. The first of the acacias were introduced from Australia to Cannes about the same time as the eucalyptus, and were planted in the gardens of Villa Victoria, where they flourished, making a vigorous growth, and blooming profusely. As the plants assumed the proportions of trees, and became early in the year laden with their golden ball-like flowers, they created an immense amount of interest, and parties were organised along the coast specially to see the new and attractive introductions. Mimosas have in more recent years been freely planted at other places on the Mediterranean coast, but the district around Cannes still retains the premier position for the culture of these beautiful trees. Several kinds are grown, and hese flowering successionally maintain a supply of flowers from January till nearly the end of April, the flowering season being at its height about the middle of February. The two earliest kinds are Acacia dealbata and A. Baileyi, the last-named being of quite exceptional beauty, and as yet but little known in this country. It was not planted until some years after A. dealbata, and its flowers did not make their appearance in the London markets until within a comparatively recent period. The supplies of the species have greatly increased during the past few years, and the quality generally has been much higher. The export of mimosa for the London and Paris markets has assumed immense proportions, and the greater proportion of the flowers are grown in the Cannes district.

Assessment of Market Gardens.—An interesting point in connection with the assessment of market gardens was, we learn from the "Glasgow Herald," raised at the Assessments Appeal Court for the Eastern District of the county of Stirling in Falkirk on the 7th inst., when Peter Mair, market gardener, appealed against the assessments on the property which he tenanted at Avondale, Polmont. The total rental of the subjects is £80, and the appellant maintained that he was entitled to have this property treated as agricultural subjects and to be assessed upon three-eighths of the annual value only. Mr. Hugh P. Black, solicitor, Falkirk, who appeared for the appellant, said that under the statute upon which the appeal was based his client was entitled to an abatement of his assessment. The subjects occupied were held under lease and were entirely devoted to the purposes of the appellant's business. The land was six acres in extent, and there were three greenhouses, which were used for the cultivation of tomatoes and plants. Then the two dwelling-houses occupied by Mr. Mair were built on the land. So far as the land was concerned, there was no doubt that it fell to be treated in the manner contended for. The only point of difference between the assessor and the appellant appared to be as to the greenhouses, but he (Mr. Black) contended that the fact that certain plants and fruit required a covering in view of the climate did not render the ground any the less a market garden. After consideration the Court agreed that the rental of the land and greenhouses should be assessed at £70 and that of the dwelling-houses at £10, the rating on the agricultural subjects being on three-eighths of the annual value.

The Gardeners' Royal Benevolent Institution will hold its annual meeting on Thursday next, the 23rd inst., at "Simpson's," 101, Strand, London, when the chair will be taken at 2.45 p.m., by Sir Harry J. Veitch, V.M.H., F.L.S. In addition to such business as receiving the report of the committee and the accounts of the Institution, and the election of officers for the ensuing year, twenty annuitants will be elected. We could have wished that it had been possible to elect a much larger number, for there are sixty-seven candidates, and all well deserving of the benefits of this excellent charity. The poll will be open at 3 p.m., and will close at 4 p.m.

New Carnations.—Mr. T. Weston, secretary of the Perpetual Flowering Carnation Society, informs us that on the 6th inst. the Floral Committee of this society awarded a First-Class Certificate to the new variety Mary Allwood. Mr. Webster points out that a First-Class Certificate can only be awarded to a perpetual-flowering carnation that has previously received an Award of Merit and made at least five additional points. Further, no First-Class Certificate is awarded unless the raiser invites the Committee, at his own expense, to see the variety growing. We are also informed that the variety which appears in the list of registered perpetual-flowering carnations under the name of Gaiety has been renamed Matador, as there is already a Gaiety in the American list.

New Park for Kinross.—The burgh of Kinross is to be presented with a new public park by Sir Basil Montgomery, Kinross House, the lord of the manor, who made the pleasing intimation at a ceremony in connection with the marriage of his son, Mr. William Montgomery. The park is to be gifted in commemoration of the happy event. The land lies by the side of Lochleven, and is admirably adapted for the purposes of a public park, the beautiful lake adding immensely to its attractions. Much gratification is felt in Kinross at this magnificent gift.

Liability for Accidents in Public Playgrounds.—Through an accident caused by the breaking of a maypole in one of the City of Glasgow playgrounds, in August last, a child was killed, and another injured. An action was brought against the Corporation by the father of the latter, and the sum of £500 was claimed. It was alleged that the pole was upwards of fourteen years old, and that it had become decayed, and should have been inspected. On behalf of the defence it was stated that the maypole had been regularly examined, and that there

was no evidence of decay. The case came before the Court of Session on December 31, when it was intimated that an offer of £75, and expenses, had been accepted.

Flora of the Australian Northern Territory.—The Commonwealth Government has, we learn from "Nature," entrusted Professor A. J. Ewart, professor of botany in the University of Melbourne, with the investigation of the plants collected during the recent Northern Territory exploring expedition, and has appointed Dr. A. Morrison, formerly Government Botanist of West Australia, to assist in the work. Dr. Morrison will reach Melbourne shortly, and it is hoped that the material available will be sufficient for the preparation of a flora of the Northern Territory.

Mr. T. W. Birkenshaw has resigned the position of head gardener at Hatley Park, Sandy, Beds., and the other day his employer, Sir Charles Hamilton, Bart., presented him with a silver tea service as a mark of appreciation. Mr. Birkenshaw has had charge of the Hatley Park Gardens nine years, and during this period many alterations and additions have been made under his supervision.

Nottingham Garden Holders' Association continues in a flourishing condition, and has been able to show a substantial balance on last year s operations. According to the annual report, the receipts during the year (including £30 brought forward) amounted to £64. The expenses were £26 18s. 3d. The association has now £151 in the general fund, £11 in the benevolent fund, and, with cash in hand, a total of £203 6s. 4d.

Rainfall at Leonardslee in 1912.—Mr. W. A. Cook kindly sends us the following record of rainfall, taken 360ft. above sea level in the gardens at Leonardslee, Horsham. January, 2.97 inches; February, 2.47; March, 4.56; April, 0.8; May, 2.16; June, 3.11; July, 1.41; August, 7.91; September, 3.44; October, 4.12; November, 2.28; December, 3.32; total, 37.83. The number of days during the year when a rainfall of 0.01 inch or more was recorded was as follows, January, 20; February, 20; March, 22; April, 3; May, 13; June, 21; July, 10; August, 27; September, 6; October, 15; November, 12; December, 22; total, 192 days.

Lily Pools that are to be met with in gardens evince a great diversity of design and differ much in size, but they all agree in being remarkable for their beauty and interest when the nymphæas have been selected with care, properly planted, and given the attention necessary to keep them in good order. A pool of simple design, and of a size so small that no more than three or four plants can be successfully cultivated, will be a constant source of pleasure, while a lake large enough to accommodate a representative collection will form a feature that will be immensely attractive throughout the summer, and abound in interest. We might mention many lily pools formed on widely divergent lines that contribute liberally to the charms of the gardens in which they have a place, but in this short note it must suffice to briefly refer to the accompanying illustration of the pool devoted to nymphæas in the gardens of Warwick Castle. The design is almost severe in its simplicity, yet it possesses much elegance, and the deep green leaves of the lilies and the various-coloured flowers as they float on the surface of the water present a pleasing contrast to the grey masonry. Additional charm is given to the scene by the closely-cut hedges and the examples of the topiary art which have as a background a conservatory which was built in accordance with a design that found favour with a past generation. It would appear that the Earl and Countess of Warwick take considerable interest in water lilies, for not only are they successfully grown at their ancient seat in Warwickshire, but at Easton Lodge, their Essex seat, there is an exceptionally good collection, and numerous fine varieties have been raised by Mr. H. Lister, who has long had charge of the Easton Lodge gardens.

LILY POOL AND CONSERVATORY, WARWICK CASTLE.

WEEPING STANDARD ROSES FOR INDOOR DECORATIONS.

Of late years the culture of weeping roses in standard form has taken a prominent place, and a well-grown specimen has few equals in decorations. As the present is the most suitable time to commence operations where one means to try a few, I am induced to pen a few notes from my own experience, so that my readers may have the benefit of what I have found somewhat expensive to acquire.

A maiden standard is the best to start with. First of all you have a better chance in potting, and can avoid many of the coarser roots a two or three-year-old plant must necessarily make in order to sustain itself, more particularly against wind, which affects such heavily-laden stems. To do this the plant naturally throws out strong and widely-spread roots, and these are by no means easily arranged in pots.

A second, and equally important reason is that you would, in any and every case, have to cut away the rose growth, so it is obvious that any excess of either roots or wood would be useless. In selecting the plant, pay attention to the stem, as this is of far greater importance than the size of the top. Unless the stem is healthy, and not what we growers style "hide-bound," it cannot do justice to the top under pot culture, where the roots have so small a run that all advantages should be afforded them of readily transferring food to the heavy head of growth and blossom they will have to support.

It matters little about having the stem of the standard in the centre of the pot, for, in the majority of cases, the pots are hidden by other small subjects, and so this does not matter so much as the fact of arranging the roots in the pots without undue cramping. They will thrive in a very small pot, compared to the amount of growth to be supported, and I would put them into as small a size as the roots will allow. Do not attempt those with large knobby roots as a base. I have not

found these do so well, and they either produce a number of suckers from the knob, or the latter gradually decays, and it is a pity to lose a good standard from this. By starting with the smallest pot you can shift on a little later, and so greatly help the plant, for I may say at once you will not be so successful in any root or soil reduction as in the case of dwarf pot roses. This is mainly because obviously the growth cannot be cut down to the base and so make a fresh start.

I prefer them to be outside, or, at any rate, as cool and moist as possible, for some time after potting, and as it is necessary they should not sway about and wrench off the young roots as they form, I have generally stood them in rows, passed a stout string or small cord between a couple of supports, and then tied each standard stem to this cord. When well set, and under glass, this support will not be so much needed against wind, of course, but we must contrive somehow to obviate the risk of their tumbling over from top-heaviness.

I have already hinted that it is advisable to prune back the wood hard at first. It is of little use leaving any of the growth for flowering during the first spring from potting. The result would be unsatisfactory, and the cultivator would lose in the matter of a good base for the future specimen. Forego this little and indifferent crop, and obtain a good base and some really fine growths in the ensuing season.

Do not hurry the growth in any way by heat. If they are in a sheltered position I would leave them out all winter, or only bring them under cover for a time should very severe weather set in. As a rule, the varieties most suited for this method of culture are rather more precocious in growth than others, and as it is the first and strongest buds that we want to encourage into long, rod-like growths as soon as possible, I would endeavour to protect them in some way as soon as they break, for one never knows when a nipping spring frost will come along. We had a good example of that during last spring.

There is no need to occupy the greenhouse with them during the first summer's growth. Have the pots upon a firm bottom, give plenty of room for the shoots to develop, and pay great attention to keeping the growth clean. It is a good plan to three-parts plunge the pots in a small bed of short manure and heavy soil. It helps to steady them, keeps them more uniformly moist, and feeds the roots to a certain extent. There is no need to have the plunging material over the whole of the ground, for as they grow the plants will be some little distance apart, and the plunging material might be put to better use.

If too many growths start, reduce them to the number your plant is best able to support. For example, five or six shoots should be ample for an ordinary-sized stem, and more especially in the first season.

Suppose we have reached this desirable stage, and are in our second year's work. Very early the following year they can be introduced to a cool house, and if they are not hurried at first the cultivator will have those lovely cascades of blossom so much admired whether at home or the early exhibitions. Remember from the first that it is what some would look upon as useless wood, because it does not flower the first season, that is of the most value in this class of rose. Provided this is fairly well matured, and not started hastily, it will carry trusses of flowers from almost every bud throughout its length.

The shoots can be arranged in many forms, but keep them as horizontal or else as pendent as the design will admit. If trained upright there are apt to be many "blind," or flowerless, growths. With the exception of guarding against wind-waving the young rods should grow as naturally as possible the first year in the open.

From the very first keep the foliage clean by a frequent use of the syringe. A very weak insecticide will do, and then you can use it freely enough to help the growth or flower buds to break easily. It is not a quantity that is wanted, but a little sprinkled over the foliage more often than many practise. It is this constant washing, when done gently, that keeps insects at bay and all healthy, much more than now and again taking such drastic measures that oftentimes as much harm as good results.

As the plants show their flower buds they must be watered freely with liquid manure. And here, also, a larger quantity of a weaker strength will be found the better plan. In fact, my own plants are watered with a weak solution whenever the watering-can is used at this stage. Much of what I call "foliage feeding" can be done by keeping the soil or concrete between the plants moist, and more especially if you can afford to give them a little stable drainings occasionally in these ground sprinklings. Of course, this is not always feasible in the conservatory, but it is largely practised by trade growers who have houses for roses alone. Keep the plants cool directly the flower truss is well formed, and before any flowers expand, thus ensuring a prolonged show of beauty that cannot fail to please.

A few varieties that we have found best suited to the standard form, but there are many others of much merit, are Pink and White Dorothy Perkins, Rène André, saffron and orange; Minnehaha, dark rose; Lady Godiva, creamy blush; Hiawatha, scarlet; Francois Foucard, lemon yellow; Excelsa, a bright scarlet form of D. Perkins; Dorothy Dennison and Christian Curle, shell pinks; and Robert Craig, with Aviator Bleriot as golden yellows. The above are all hybrid Wichuraianas, and have particularly long, slender growths that droop over even without the weight of blossoms.

In mentioning that these could be trained in many forms I omitted to hint of their extreme beauty when trained over one of the numerous contrivances now on the market, that are designed much after the shape of an opened umbrella. A. P.

Calceolaria deflexa.—Placed under favourable conditions in the greenhouse this calceolaria will bloom throughout the winter months, its bright yellow flowers being much appreciated at this season. It is an old species, being formerly known as Calceolaria fuchsiæfolia. It is reputed to be one of the parents of the popular Calceolaria Burbidgei, but different opinions have been expressed on that point.—W. T.

Early Figs.—It is not absolutely necessary that pot fig trees should be plunged in fermenting materials; but as they are subject to early attacks from red spider, fermenting materials play a prominent part in their cultivation, not only in keeping up the heat, but also in maintaining suitable atmospheric conditions. A steady bottom heat of about 75 degrees, with a night temperature of 60 to 65 degrees on mild nights, and 70 to 80 degrees by day, with a little fresh air admitted on all favourable occasions, will be found suitable for trees started in November. Second houses containing trained trees may now be closed, while late houses must be kept cool by liberal ventilation except in severe weather.—F. JORDAN.

ISOLOMA HIRSUTA.

Quite a bank of this pretty free-flowering Gesnerad was shown at the Horticultural Hall on January 7. It possesses many desirable features, yet at the same time is not often met with. In the first place, it can be readily propagated by means of cuttings, division, or by seeds; next, it will grow readily in a warm, light greenhouse, providing there is a liberal amount of leaf-mould in the soil; and, lastly, its bright-coloured blossoms are borne over a considerable portion of the year. They are of inflated tubular shape, about a couple of inches long, and, in common with the stems and leaf-stalks, are thickly clothed with brownish hairs. The leaves, too, are also hairy.

This Isoloma is nearly related to the garden varieties of Tydæa; indeed, these last are by some authorities included in the genus Isoloma. In I. hirsuta, however, the lobes of the flower are not spreading at the mouth, as in most of the Tydæas. The specimens shown were from three to four feet in height, but they will flower freely when considerably shorter than that. Though exceedingly pretty when grouped together in the greenhouse, Isoloma hirsuta does not travel at all well, and had the plants exhibited not lost a good many of their flowers in this way, they would have made a much brighter display. W. T.

SINGLE-FLOWERED CAMELLIAS.

For some years now camellias have not occupied the prominent position in our gardens that they at one time did, but signs of a return to favour are in their case becoming more or less evident The public taste has, however, quite veered round from the very double flowers, with a hard and formal outline, to those which are either semi-double or single. A feature of the single camellias, and a very beautiful one, is the large brush-like tuft of conspicuous yellow stamens in the centre of the flower.

At the meeting of the Royal Horticultural Society on January 7, cut sprays of several delightful single-flowered forms were shown from the nurseries of Messrs. William Paul and Son, at Waltham Cross, where camellias have long occupied a prominent position. Noteworthy among these varieties were Adelina Patti, pink, edged with white; Juno, white, flaked pink; Jupiter, rosy-red, a fine large flower; Minerva, deep rose; Lady M'Kinnon, crimson, marbled white; Tricolor, pale pink, flaked crimson; Snowflake, pure white; Vesta, bright red; and Waltham Glory, rich deep scarlet, particularly telling.

Besides the foregoing single camellias, there are also Camellia Sasanqua, with small rose-coloured flowers. Of this, which blooms earlier than the forms of Camellia japonica, there is a variety with white blossoms, and another with variegated leaves. I have found that Camellia Sasanqua can be readily struck from cuttings.

Another single-flowered variety is the Chinese cuspidata, which was given an Award of Merit last spring. It has small white flowers, and has proved to be quite hardy on the slopes of Coombe Wood Nursery. The Tea-plant is now regarded as a camellia under the name of C. Thea, and while its flowers are single, they are less conspicuous than those of the others.

A grand camellia with semi-double flowers of quite an informal nature is C. reticulata, which is seen to the best advantage when planted out in a conservatory, or similar situation. W. T.

NEW PLANTS, ETC.

LINDENBERGIA GRANDIFLORA.

Although listed in the Kew Hand Book of Herbaceous Plants, and, consequently, a more or less hardy plant, Lindenbergia grandiflora, is undoubtedly a very fine greenhouse plant for flowering during winter. As shown it was about 2½ft. high, the stems bare for a few inches at the base, but clothed above with soft, small leaves that were almost hidden by a profusion of yellow flowers. This same plant had been continuously in bloom for two months. It is a native of the Himalaya, belongs to the Order Scrophulariaceæ, and is by no means new, though not common. For winter-flowering it is well worth cultivation. A.M., R.H.S., January 7. Messrs. Jas. Veitch and Sons, Chelsea.

LÆLIA ANCEPS ROEBLINGIANA.

A distinct variety of L. anceps, but as the plant was sent from the United States, in spike, the blooms were not seen at their best. The purple and pale, almost white, colouring of the petals appear in streaks and flushes, and not in the usual solid or delicately-shaded fashion. A.M., R.H.S., January 7. C. G. Roebling, Esq., Trenton, New Jersey, U.S.A.

ODONTONIA FIRMINI.

This bigeneric hybrid is derived from a cross between Odontoglossum crispum and Miltonia vexillaria, and it most resembles the latter parent. The flowers are flattish, but the lip is not so abnormally large as in a Miltonia. The colour is white, with pink flushing and a yellow disk. A.M., R.H.S., January 7. M. Firmin Lambeau, Brussels.

CYPRIPEDIUM AMAZON.

A very large form that has evidently descended from C. insigne Harefield Hall. It has a very broad and rounded dorsal sepal that is very largely coloured green, but has a white apex. The wide petals are green and brown, and the lip is of similar hue. A very bold cypripedium, but not exactly a pretty one, though its style and form is very popular just now among fanciers. A.M., R.H.S., January 7. F. Mentieth Ogilvie, Esq. (gardener, Mr. Balmforth), The Shrubbery, Oxford.

CYPRIPEDIUM IONA.

A pretty cypripedium of medium size, with fairly broad segments, and slightly drooping petals. The ground colour is creamy-white, and this is freely dotted and shaded with rich rosy-purple. A.M., R.H.S., January 7. Duke of Marlborough, Blenheim Palace, Woodstock.

ODONTOGLOSSUM GEORGE DAY.

Though not so fine as O. Smithi, this hybrid between O. crispum and O. Rossi rubescens is very attractive by reason of its purple spotting, and chocolate-brown shading on a white ground. As is usual, O. Rossi has impressed itself strongly on its progeny. A.M., R.H.S., January 7. H. S. Goodson, Esq. (gardener, Mr. G. Day), Fairlawn, Putney.

ADIODA ST. FUSCIEN HEATONENSE.

In this little orchid Cochlioda Noezliana and Ada aurantiaca have been combined. The latter parent has exerted the greater influence, but the spike is looser and the flowers rather more expanded than is Ada aurantiaca, but the segments are pointed, and the blooms are of a deep crimson-red colour. Certificate of Appreciation, January 7. Messrs. Charlesworth and Co., Hayward's Heath.

CYMBIDIUM ALCINEDA.

A fine variety obtained by crossing C. Alcibiades with C. insigne Harefield Hall. The broad white dorsal sepal has a bright green basal area, and some lines of purple spots. Lip and petals are broad, green, shaded with brown. A.M., R.H.S., January 7. Messrs. Charlesworth and Co., Hayward's Heath.

CALIFORNIAN BOX ELDER.

This is a variety of the well-known Box Elder (Acer negundo), which is distinguished by the varietal name of californicum. Under cultivation in this country it appears to be of more vigorous growth than the type, although it cannot be expected to grow into a very large tree, for, at its best in California, it is rarely met with of a greater height than fifty feet. Jepson, in his "Silva of California," p. 269, says that its general height is between twenty and fifty feet. It grows in the vicinity of streams about the coastal ranges of the country, but is nowhere found in large quantities, small groups and isolated specimens being more common than large colonies. The leaves are composed of three principal lobes, which are deeply cut about the margins. It is best known in this country by its golden-leaved form, which is variously known as A. n. californicum aureum, and A. n. odessanum. This is of vigorous growth, with showy, golden foliage, which possesses the advantage of keeping its colour well from the time the leaves appear in spring until they fall in autumn, whereas the colour of some golden-leaved subjects suffers from sunburn before the middle of summer. It is an excellent subject to include in beds or groups of trees and shrubs arranged for the colour effect produced by their leaves. W. D.

LINDENBERGIA GRANDIFLORA.
Flowers yellow. A.M., R.H.S., January 7. Messrs. J. Veitch and Sons, Chelsea.

BASKET-MAKING WILLOWS.

During the later years of the last century the cultivation of basket-making willows declined to a considerable extent in the British Isles, due partly to increased importations of foreign-grown rods, which could be purchased at a cheaper rate than those grown in this country, partly to boxes and barrels superseding baskets and hampers for various kinds of agricultural and horticultural produce, and, to some extent, by the curtailment of manufactured articles in willow exported to foreign markets. The last few years have, however, witnessed a revival of interest in willow culture, for the trade in basket work has expanded to a considerable extent in certain directions, and cultivators find that they can obtain satisfactory returns from their willow-beds if the best kinds are grown.

The use of wicker-work chairs and other kinds of furniture appears to have brought about this change, whilst other things which have contributed to the present brisk trade in basket-work are the motor-cycle and increase of large laundries. In the former case there has been a large demand for basket-work side-cars, and in the latter for linen baskets.

Preparation of Willow Beds.

It is not, however, with the manufacture so much as with the cultivation of willows that we have to deal, for, although some manufacturers grow their own rods there are many people who grow the rods and dispose of them to the manufacturers, and other persons who have the necessary ground might add to their income by the same means.

When commencing the culture of basket-making willows, the first point to grasp is that the best results can only be obtained by proper cultivation, and the reason why so many beds have turned out unsatisfactory can often be traced to neglect. The popular idea that willows can be grown upon any wet ground is quite wrong, and marshy ground should not be planted until steps have been taken to drain superfluous moisture away. This may sometimes be done by opening ditches or drains every 12 or 20ft. through the ground, especially if a fall can be obtained to a pond or river, but in any case it is no use planting in ground which is in a constant state of saturation. An occasional flooding of the beds does no serious harm, providing the water drains away again quickly; in fact, in dry weather, irrigation is attended by good results. Another point for consideration is the proper cleaning and working of the ground, for it is little or no use planting in dirty or badly-prepared ground. In every case, land which is to be occupied with willows should be ploughed deeply or trenched, if possible, a few months before it is planted, so that it may be well harrowed a time or two between ploughing and planting.

Planting Willows.

Cuttings about twelve inches in length are generally used to form a plantation. They are usually made with a sloping cut at the lower end, so that they may be pushed into the ground with the minimum amount of bark injury. The best time for planting is considered to be February and early in March, for, if planted in autumn, a frosty period in winter tends to loosen the cuttings. They are planted in straight lines, varying from 2 to 3ft. apart, according to the strength of the variety used, less space being left between the plants in the rows, and planting consists of pushing the cuttings into the ground to a depth of nine inches, afterwards treading the soil firmly about them. The majority take root, but any vacancies which may occur are made up the following spring. During summer the ground is kept clean, either by hand hoes or by a horsed cultivator, care being taken not to injure the young shoots. The rods produced the first year hardly pay for the cost of cutting; they are sometimes cut, however, but if very weak they are usually left for a second year. The second year a fair crop may be expected, but a bed will not attain its maximum yield until the fourth or fifth year, after which time it will go on yielding indefinitely, providing careful cultural methods are followed out. Every year the beds must be thoroughly cleaned up as soon as the crop is cut, and should weeds appear, they must be cleaned again before the young shoots are far advanced. At least every other year a surface dressing of manure must be given. This may be well-rotted farmyard manure, sewage, or an artificial fertiliser.

Cutting the Crop.

The cutting of the crop is an important operation, for a bed may be easily ruined by improper cutting. The object in view is to keep the crowns of the plants as compact and near the ground as possible; therefore, the rods must be cut to the base each year, not left an inch or two long. By leaving an inch or two at the base of each shoot every year, the stocks soon assume a wide, sprawling habit, which has a serious effect upon the yield, and makes it very difficult to clean the beds and remove the crop.

Some kinds are cut in mid-winter and others in the early part of spring. The former embraces those which are to be used with the bark on, and those which are to be prepared as buff rods. Buff rods are usually used for fine kinds of work and the colour is obtained by steeping them in hot water previous to peeling. White rods are obtained by spring peeling. The shoots are cut when the sap is beginning to run; they are then tied in bundles, and stood in water to keep them in the proper condition until the peelers can deal with them.

Kinds to Plant.

Although a great many varieties of willows are grown they belong to comparatively few species, and each district appears to possess two or three sorts which are considered superior to others. Strange to say, if the best sorts from one district are removed to another they rarely maintain their reputation. That certain varieties or forms have in the first place originated from single specimens is evident, for it is invariably found that a local variety is made up entirely of male or female plants.

Salix triandra is, perhaps, the most prolific in varieties, for nearly forty different forms are grown. These have each their little peculiarities to the expert willow-worker or grower, but to the ordinary individual many of them look absolutely alike. In some cases, however, it may be noticed that the rods are more liable to branch than in others. S. triandra is one of the most important willows for the better classes of work, and usually commands a

S. purpurea is another species which produces a number of varieties suitable for fine kinds of work. Some considerable difference is noticeable in the strength of the rods of different forms, and it is, perhaps, easier to distinguish the varieties of this than those of other kinds.

S. viminalis is one of the best strong-growing sorts. To the basket-maker any variety of this is known as an osier, other species all being willows. The term "Long Skein" or "Long Skin" is often used in connection with the best samples of this species, and each district appears to possess a long skein, which is superior to any other long skein in the country. The species is well-known as one of our commonest British willows, and is one of the most widely grown of basket-making kinds.

S. daphnoides, the Violet Willow of Europe, is favoured in some localities on account of its long, strong rods, but other growers consider it too coarse for the better kinds of work. It is easily recognised by its purplish stems which are covered by a glaucous bloom.

S. fragilis is not grown very largely in this country, but it is one of the kinds imported. It is said to be grown extensively in Madeira.

S. alba vitellina, the golden-stemmed willow, occupies a place amongst basket-making willows, but it is grown most largely for the provision of rods for tying purposes.

S. rubra and S. hippophaifolia are strong-growing kinds, which are sometimes used by basket-makers, while S. pentandra, S. cordata, S. lucida, and S. alba are other kinds which sometimes enter into the basket-work trade. W. D.

Bouvardias.—These beautiful greenhouse flowering plants seem much less grown than was formerly the case, one reason apparently being that their flowers are not big enough for present-day tastes. Perhaps if they bore flowers as large as Malmaison carnations they would once again become popular. Certainly these last-named have now quite taken the place of the bouvardia as a button-hole flower. In any selection of bouvardias, the deliciously-fragrant B. Humboldti corymbiflora, with its pure white, long-tubed flowers, must on no account be omitted, while other desirable white-flowered varieties are Jasminiflora paniculata and Pride of Brooklyn. Of scarlets I should name President Cleveland and King of Scarlets, and of pinks Mrs. Robert Green and Priory Beauty. The best doubles are Alfred Neuner, Bridesmaid, President Garfield, and Hogarthi flore plena.—T.

Asperula hexaphylla.—As valuable as Gypsophila paniculata for associating with other cut flowers, Asperula hexaphylla has the merit of blooming almost two months before the favourite Chalk Plant, and of thus coming in usefully for a season when such subjects are often in demand. It grows about a foot high only. The flowers are small, pure white, and most graceful: while the neat, narrow foliage is in keeping with the character of the flowers. This plant is one of the Woodruffs. It can be grown in any good border, and is accommodating enough to flourish in the shade, though to keep the flowers pure it ought not to be under the drip of trees. Seeds can be sown in spring under glass, in the same way as those of other hardy perennials, and it is also increased by division in spring.—S. A.

GARDEN COLOUR SCHEMES.

Each year the ornamental garden should be newly considered before a decision is arrived at as to plants of bedding character that are to be used for it. If this is done early enough seed-ordering is simplified, and a heterogenous colour mixture will be avoided. Almost without exception the poor effects in our pleasure grounds, large or small, are caused by false colour harmonies, the lack of brilliance, or the predominance of the garish. However fine may be individual plants, however well grown the flowers, dissatisfaction is bound to result unless care and art have gone to the selection and mingling of hues.

It is sometimes objected that the gardener should not be called upon to be this kind of artist, as well as a skilled floriculturist. We can all agree that a man may be colour blind and yet be an excellent gardener, but, happily, a very little study will enable the average man to appreciate beauty in colour, and the uglinesses that occur when colours clash; to realise how to make the best use, too, of his existing field of action, for adaptation to the permanent environment is one of the important secrets.

In earliest spring a survey should be made of the grounds in order to note what is already there in the way of colour. To begin with the buildings must be taken into consideration. A cold grey or stone-white house will never become a pleasing part of the garden landscape, as it should, unless it is embowered in evergreen, gold, or copper foliage, and has a sufficiency of bright flower hues about it. A vivid red-brick house will need toning down by some evergreen foliage, but the best softener will be afforded by the Virginian creeper tints, or such mulberry shades as are afforded by the too seldom employed purple ivy, the copper beech, and Prunus Pissardi; maroon flowers, such as are to be found in plenty among dahlias, hollyhocks, stocks, hyacinths, chrysanthemums, violas, asters, and geraniums, are of immense service; a banked-up border of darkest crimson Snapdragons, for instance, varied by auricula-eyed Sweet Williams, would be a pleasing feature of the front garden.

It must be observed that a red-brick house is not always garish, for age and atmospheric influences will tone the bricks, and even tiles, to a chastened coppery terra-cotta hue that is always pleasing. Sober old walls, whether of the dwelling, or forming boundaries, are the fairest backgrounds for blues, golds, salmon, scarlet, orange, lemon, mauve, white, or violet. Again, a so-called white house is not always cold-looking; the limewashed walls of ancient cottages, for instance, seem to reflect or repeat the faintest rays of sunshine, blush-rosy with sunrise, flame deepening to coral with the sunset, and are generally of that cream shade that wielders of the brush apply, by yellow ochre washes, to drawing papers before adding the blues or greens that constitute a landscape. There are no flowers that are not exquisitely suited by such humble walls, and modern builders are beginning to add some constituent to stucco that gives it something of this lightsome effect; probably the most charming of all results are gained by massing rose-pinks and carmines in these cases.

New gravel, or paths in a gravelly locality which will often be redressed, are a danger to the garden colourist, for genuine rose colour is antagonistic to the orange hue, so much so, indeed, that roseries in gravel should consist of salmon and scarlet varieties, with white, yellow, maroon, and apricot, and the carmines and pinks be avoided; the gay pinks of asters, stocks, and geraniums, sweet peas, too, should be kept for lawn beds far removed from any walks. Gravel, on the other hand, intensifies by contrast the richness of blues and violets. Where lawns are joined by evergreen, or green deciduous shrubberies, the introduction of gold and silver, or cream variegated foliage, will pleasingly break the monotony, and the gardener should make a point of raising bedding plants of suitable leaf-colouring.

Where walks are grey-paved and old rockeries abound, a decided lack of verdant green may be the fault. Then dahlias and cosmeas are admirable tall plants to grow, and violas, calceolarias, ivy-leaved geraniums, scabiouses, delphiniums, and hybrid pyrethrums will improve the summer show, while mossy saxifrages and primroses, polyanthuses, campanulas, and pansies offer relief even during winter.

Many an old garden, among grey walls or fences, suffers year after year from a deficiency of brilliance. The cure for this is simple. Let the gardener concentrate his energy on the raising of gorgeous cannas, gaillardias, coreopsises, mimuluses, calceolarias, zinnias, striped antirrhinums, which are gay in the extreme, African and French marigolds, calendulas, and gazanias, and obtain orange and scarlet dahlias and chrysanthemums, day lilies, too, in plenty. Some royal blue delphiniums and anchusas, blue violas and asters, among these, with a sprinkling of maroon flowers or foliage, will create splendour indeed.

The habit of sowing seeds in mixture is one of the worst errors from the colourist's point of view; with some plants the results are fairly harmonious, stocks and asters are an example; with others, such as verbenas, zinnias, and Snapdragons, the consequences are scarcely ever artistic, as scarlet flowers appear next to magenta, or vivid salmons near dull pinks, to say nothing of the delicate peach-mauves of the first-named being killed by juxtaposition with bright blues. When no mishaps of this sort occur the mixed beds of flowers are but half as effective as beds of self colours, or well-arranged colour schemes would be, and are incapable of yielding any real note in the garden landscape. A small villa garden requires to possess but two or three chief colours each season, while the most striking displays are gained by choosing but one principal flower hue for the summer beauty.

CYPRIPEDIUM IONA.

Flowers cream-white, with rose-purple markings. A.M., R.H.S., January 7. Duke of Marlborough, Blenheim Palace, Woodstock.

THE POSSIBILITIES OF A SCHOOL GARDEN.

VI.—The Teacher.

After enlarging, as I have done in the preceding articles, on the possibilities of a school garden, and the value of gardening as part of the curriculum in a rural or a town school, either for the matter of that, it is necessary, in summing up, to pause and say, *but*, with emphasis on the latter word, everything depends on the teacher. Perhaps not everything, but certainly a very great deal, and the responsibility rests with this individual whether the garden is made to serve its full purpose or not. The elementary school teacher of to-day has claim to wide sympathy and consideration, for while no one can say that he is overpaid, so much is expected of him. Subjects have been introduced into schools, chiefly of a manual character, that were unheard of when many present-day teachers were in training, and it must be said, to the credit of scores in the profession, that they have advanced with the times by qualifying themselves to teach them.

I am almost tempted to say that really successful teachers of school gardening are not made; they are in a manner born, by which I mean to say, Nature has endowed them with a love for gardening, which helps them to an almost unlimited extent, and I cannot conceive how a man can teach gardening successfully unless he is fond of it. The teacher who likes gardening for its own sake has a knack of getting his pupils to like it also; he sees its possibilities, and, being thoroughly interested, he and his class are able to demonstrate those beautiful words of Ruskin's that "flowers only flourish rightly in the gardens of those who love them."

Strange though it may seem, I know a number of teachers who never discovered their fondness for gardening until they began to teach it, and now they may be described as really enthusiastic horticulturists. These men probably never knew that they liked gardening because they had never been brought into touch with it, and somehow school gardening differs from other gardening, inasmuch as it is not routine work, with so much produce as its end and object, but a field of discovery, as it were, in which the difficulties and failures may be made use of in teaching, just the same as the successes and the triumphs.

When the teacher is in the garden he finds himself moved to a different sphere than the ordinary routine of school work. He may be a good gardener and fully qualified, but he is no longer master of the situation as he is when teaching arithmetic or geography. While he is a teacher he is also a learner with the book of Nature stretched before him, and if he is of the type who can develop a spirit of inquisitiveness amongst his boys, he knows that, at any moment, one of the lads may come up and put a question that he cannot answer offhand. I stood in a school garden one day when a boy made a discovery, and at once asked the master to explain it. The master, a splendid teacher, and a man past middle age, answered the boy in these words: "I don't know, my lad; but we'll go and try to find out." There you have it in a nutshell, and this is the spirit of the school garden, or what it should be, learning together, as it were, teacher and scholar going hand in hand to unravel the secrets of Nature as they present themselves. Was this not far better than giving an evasive answer, or maybe, wrong information on a point about which the the teacher was not clear? "We'll go together, and try to find out." If you made an inspection of schools that are the most successful in the matter of gardening and allied work, I think you would find out that the whole secret of it is that mutual understanding on the part of the teacher and the boys to find out. I have seen boys discover an insect in the garden, and at once go with it to a certain book in the teacher's cupboard, but without any instructions to do so, and pore over it with that same object—to find out. They had done it before—with the teacher; the habit had grown, and with it the self-reliance of the boy.

There are those in education circles who say that gardening ought to be made a compulsory subject in rural schools. If this happened I am afraid we should find a good many round pegs in square holes, and, on the principle that one volunteer is worth a dozen pressed men, I like to see it come voluntarily. The teacher who asks the education authority if he may have a school garden means something in a general way, and if he does not make a complete success of it straight off, he should not be subjected to severe criticism, but be led on, as it were, and be given helping hints which teachers of a progressive type are always glad to receive and make use of. School gardening in this country is progressing nicely. The teachers who have taken it up are a volunteer army, and, though, as one would naturally expect, they have not all succeeded alike, it must be admitted that it has been left to the keen schoolmaster to demonstrate what the possibilities of a school garden are in education.

I am aware that a good many teachers have taken up school gardening without any particular training in horticulture, and there are people who criticise this course of action. I have known local managers to ridicule the idea of a schoolmaster teaching gardening for no other reason than he is a schoolmaster, and if one had suggested a mistress taking it, their horror would have been unbounded. "What can he know about gardening?" is the not uncommon question asked when the matter is brought up at a managers' meeting, but these good people of limited vision forget that, after all, school gardening, as gardening, is elementary gardening: in fact, the type of gardening that hundreds of men excel at without any special course of training, but they do not realise that, if the schoolmaster is a bit deficient in his knowledge of gardening, he can acquire that knowledge, and he has, at any rate, been taught to teach, and no matter how good a gardener a man may be, he cannot possibly get the most out of a school garden if he is unable to teach. I am decidedly of the opinion that the teacher is a more suitable person to have charge of a gardening class than a local gardener or local instructor, and I say this without being in any way uncomplimentary to the latter, who may be a most excellent gardener, but has never been trained to teach, and it is more difficult to impart knowledge to juvenile humanity than it is to grown-ups. Though I have known men without any particular training in or knowledge of horticulture make successful teachers of school gardening, they belong to the type of men who have capacity for mastering things they take in hand, and it is desirable that teachers of school gardening should have a sound knowledge of horticulture as far as it applies to a school. With this end in view it is hoped that better provision will be made in the future for young men during their course of training to acquire some knowledge of practical horticulture.

The parent of the boy, the man in the village streets, displays an interest in the school garden because it is the one part of his son's education that he knows something about, and in respect of it he feels that he is in a position to criticise. It is well for the teacher to realise this, and to remember that when he starts school gardening the men of the village, the fathers of the boys, treat it as a joke, sit on the fence and wait to see it fail. If, however, they find out a bit later on that the school garden is a bit better than their own, and produces a heavier weight of produce than any similar piece of land in the parish, their views change, and the schoolmaster goes up a few notches in their estimation of his abilities. These men, it should be remembered, know nothing about the meaning of correlation, and their estimate of the schoolmaster stands or falls by the garden. It is desirable that the school garden should be a force in the village, a demonstration of what is good in gardening; in short, a success as a garden, apart from anything else, and I mention this to show the desirability of the teacher being a good cultivator. It is here where he may be a bit deficient at the outset, but he can acquire the knowledge he may lack much more easily than the local practical gardener can ever learn to be a teacher.

H.

CORONILLA GLAUCA.

This little shrub, though usually treated as a greenhouse plant, proves quite hardy in the warmer portions of our islands, such as are to be found along the southern shores of Devon and Cornwall, where, in the dark winter days, it adds its clear yellow to the brighter tints of the same colour provided by Cytisus racemosus and Jasminum nudiflorum, to the sulphur of Chimonanthus fragrans, and the twisted gold leaf of Hamamelis arborea. This coronilla is common in Devon and Cornwall, where it may be seen in the humblest cottage plots, as well as in the finest of private gardens, while in some nurseries numbers of plants are grown, and in one, a few days ago, some dozens, about two feet in height, were in profuse bloom, their blossoms making an effective display.

Wherever seen it is welcome in the months of November, December, and January, for the yellow flowers associate charmingly with the subdued tints of the glaucous leaves. To show how extensively this plant is grown in the south-west it may be mentioned that in December a thousand flowering sprays were forwarded to London for the purposes of a lecture by a friend, who had no difficulty in procuring the quantity. Near London the climate is too cold for this coronilla in the open, but it makes an excellent conservatory plant. It is easily raised from cuttings, which strike readily in sandy soil if kept close for a short time. There is a variegated form, which is, however, decidedly inferior to the type. C. emerus bears yellow and chestnut flowers, and blossoms in the spring, but is not so effective as the subject of this note when in full bloom.

WYNDHAM FITZHERBERT.

GOLDEN IVIES.

The question whether ivies are injurious or otherwise to buildings over whose walls they are allowed to spread does not appear to have been answered to the satisfaction of all who write on gardening matters. Quite recently there has been a brisk discussion in which it was firmly held on one side that ivy is distinctly injurious to buildings on which it has become established, and on the other that the plant is incapable of doing damage to structures of a substantial character. Those who take extreme views with regard to the capacities of ivies for doing damage are not likely to soon obtain a solution of the question to which reference is made. They overlook the fact that the ivy is capable of doing injury to its supports if it is allowed to grow unchecked for a considerable period, and that with comparatively little pruning its injurious proclivities can be so restrained as to render it quite harmless.

For example, when allowed to grow untended, a dense mass of side shoots will be produced, and project a foot or more from the face of the wall. Such growths become a harbour for birds and vermin, and those growths at the upper part of the wall will find their way into the gutters and pipes provided for carrying the rain-water from the roof and choke them up. As the result thereof the water will overflow, run down the walls, and, in course of time, so saturate them as to render the rooms more or less damp. This is not all; some of stronger growths will penetrate any crevices there may be in the walls, and in course of time they may possibly loosen the brick or stonework, if they do not dislodge any portion thereof. Those who have visited old abbeys and other ruined buildings will have noticed the stout ropelike stems pushing freely between the stonework they have loosened, and probably they will have seen also large blocks that have been overturned by them. Many such blocks have come under my notice, and more than one of my friends have had their houses so damp as to be well-nigh uninhabitable as a consequence of the overflow of the water from the gutters.

There can be no question as to the power of the ivy for doing harm, but it is so simple a matter to restrain its injurious tendencies that no excuse can well be found for allowing it to damage walls over which it is trained. All that is necessary to prevent the slightest injury is to prune the ivy annually, and in performing this operation, be careful to cut back all growths that are likely to extend beyond the allotted space, and to give special attention to those about the eaves and the water conduits. The pruning can be done in March or at midsummer, as may be preferred. In pruning ivy in spring the practice is to cut the whole of the growths close back to the stems attached to the wall with a pair of shears, and to remove the whole of the leaves. The brown leafless shoots present a bare appearance for a time, but it is short, as when new growth commences the walls become clothed with leaves of the most pleasing verdure. In the midsummer pruning all the projecting shoots are cut close back to their base with a knife, and the leaves on the shoots attached to the wall remain intact.

The object of these notes is not, however, to give advice on ivies, but rather to call attention to a few of the most attractive of the varieties remarkable for their golden variegation. In a reference to these beautiful forms, it is not out of place to mention the conflicting opinions that are from time to time expressed with regard to the capability of ivies doing damage, and to show that any injury they are able to do can be readily prevented. The golden variegated varieties require the same attention as those with green leaves, but being less vigorous in growth, are not likely to grow beyond bounds so soon after being planted in their permanent positions.

The golden-leaved ivies have much to recommend them, and should be planted rather more freely than is generally the case because of the bright appearance they present during the greater part of the year. The variegated Irish ivy (Hedera Helix canariensis variegata) has much to recommend it for covering large wall spaces, for, as in the case of the green form, it is free in growth, and has large leaves, which are richly marked with gold, and produce a bright effect. The variegated Irish ivy is admirably adapted for furnishing pillars of rustic or other wood alongside walks or in other prominent positions, because of its free and bright growth. Being a vigorous grower, and with leaves much larger than even the normal form of the Irish ivy, the Tooth-leaved ivy, best known under its scientific name as Hedera Rœgneriana dentata, is one of the most handsome of the large-leaved ivies and of much value for covering wall spaces of big buildings. The leaves are relatively very large and distinctly handsome, and in the variegated form known as H. R. dentata aurea variegata, they are finely variegated with rich yellow. Their shape and markings are admirably shown in the accompanying illustration.

HEDERA RŒGNERIANA DENTATA AUREA VARIEGATA.

A handsome variegated variety of this large-leaved species; the illustration represents one of some richly-coloured plants exhibited at one of the R.H.S. meetings by Messrs. J. Cheal and Sons.

Quite distinct in character from the foregoing is H. H. spectabilis, which is not less vigorous in growth than the green-leaved Irish ivy, but has smaller leaves. During the earlier stages of growth the leaves are more or less of a golden hue, and specimens covering large spaces are singularly effective. The golden colour is retained during the greater part of the summer when it gradually disappears, and the leaves become of rich bronze-green, with a golden leaf here and there to remind the owner that the plant has not returned wholly to the green type. Another handsome form is H. H. latifolia maculata, which is free in growth, and has rather large leaves that, instead of being suffused wholly or in part with gold, are distinctly blotched with pale yellow. It will thrive and retain its distinctive colouring in almost any position, and is decidedly useful. H. H. digitata variegata is perhaps the best of the golden ivies, with finely-divided leaves, and is useful for the variety it affords.

In planting ivies for covering walls, trellises, and pillars, the preferable course is to obtain strong plants, well grown in six or seven-inch pots, as these quickly become established and grow away vigorously. The soil should be broken up to a depth of twelve inches or so, but the addition of manure is unnecessary. For the variegated varieties, the soil should be distinctly poor, and where the soil is a strong loam or clay-loam, it will be an advantage to add mortar rubble, gravel, or chalk in moderate proportions when the ground is being dug over. G.

LETTUCE WAYAHEAD.

We already have such a number of good cabbage lettuce that some may think another is not required, but there is always room for a superior variety. The variety under notice is a very good one, either for frame culture or the open ground, and when better known, should supersede some of the varieties now grown. While recognising the value of standard kinds, I fear there is a tendency among many gardeners to conservatism with respect to many things they grow. It is wise to rely on well-known varieties of salads and vegetables, but it is progressive to test sorts which are good, but may not be generally known. It is by such means we find out what is best to grow in our own particular district. One may grow this Wayahead lettuce with confidence; I do not think there are many firms who offer it, but it can be obtained from Messrs. J. Carter and Co.

PAUL T. MORE.

Allamanda violacea.—The dominant feature of this allamanda is the colour of the blossoms; in nearly all the cultivated kinds these are of some shade of yellow, whereas in this species they are of a rosy-purple hue.

SOME OF THE NEWER BALSAMS.

The introduction of the pretty free-flowering Impatiens Sultani somewhere about thirty years ago, served to direct attention to the desirable qualities of some members of the Balsam family, apart from the annual species, which had long been grown in gardens. Soon after I. Sultani, the rich magenta purple-flowered I. Hawkeri was introduced, but it proved so subject to the attacks of an insidious mite that it did not hold its own long in many gardens. Like I. Sultani, it is of perennial duration, and we have now several species of the same section, all valuable in the warm greenhouse for their brightly-coloured flowers and continuous blooming qualities. One of these—Impatiens Holsti—is herewith illustrated. Its habit of growth and exfusion, while they are borne more or less plentifully almost throughout the year. I have seen this Balsam at different times in good condition bedded out at Hampton Court. One of the last species to be introduced is I. Herzogi, whose flowers are larger than those of I. Holsti, and of a distinct orange-salmon shade. They are produced at all seasons,, and are particularly telling during the half-light of a dull autumn day. At Kew a hybrid has been raised between I. Herzogi and the old rosy-lilac-coloured I. platypetala. It is known as I. kewensis, and has flowers of a ruby-red colour, though among them there is a certain amount of individual variation. Like the rest, it is almost continuous flowering; indeed, one rarely visits Kew without seeing some good examples in bloom.

The culture of these Balsams is very simple, for while seeds of some can be

IMPATIENS HOLSTI.
As grown for Decorative Effect at Kew.

treme floriferousness is well shown, therefore it will suffice to say that in colour the blossoms are of a bright vermilion tint. Taken altogether, it is more robust in constitution than I. Sultani, and given a favourable summer, it will flower freely when used as a bedding plant. Impatiens Sultani is a native of East Africa, and I. Holsti also comes from the same region. It was introduced by way of the Berlin Botanic Garden.

A larger grower than any of the above is Impatiens Oliveri, introduced from Uganda about ten years ago by Sir John Kirk, who first sent seeds to Kew. It is one of the largest members of the genus, and will form a bushy growing specimen six feet or nearly so in height, and about as much through. The flowers are large, and in colour pale lilac with a pinkish suf- obtained, all are readily increased by means of cuttings, which must not be kept too damp and close, otherwise they are liable to damp off. In a compost made up of loam, leaf-mould, and sand they will grow freely if given a good light position in an intermediate house. K.

Begonia manicata.—Now we have so many winter-flowering begonias in cultivation this old Mexican species is much less grown than formerly. Still, it is well worth a place in the intermediate house, where its blossoms, though not showy, are decidedly pretty. This species forms a short, stout stem, clothed with large shining green leaves, while the flower stems reach a height of about three feet. On the branching upper part the small pink flowers are freely borne. There is a variety in which the foliage is irregularly blotched with yellow.—S. W.

THE BEST TIME TO PROPAGATE PERPETUAL CARNATIONS.

The man who thrusts his hand into a hornet's nest is invariably stung, and he who challenges a generally-accepted theory is likely to be somewhat severely criticised. However, I will risk all this, and venture to state that good cuttings rooted in January produce finer and better plants of perpetual-flowering carnations in twelve months than those rooted in October, November, or December, or any other month of the year.

Beyond being able to give practical proof, I would point to the fact that the cuttings inserted during October and November are of summer-made growth; this is much harder, and does not become free growing wood, also the dull weeks that lay before it are not conducive to a free growth. Consequently, the young plants remain half dormant until early in the spring, the stem or base all the time becoming practically case-hardened, or they are stood upon a shelf in a warm greenhouse, and forced into making an artificial growth, which is naturally weak, and the spring finds the young plants in a more or less exhausted state, but usually more than less.

Let us take, on the other hand, the case of the January-rooted cutting; it is produced during the autumn and early winter in the greenhouse, consequently, should be free from all taint of pest or disease. When it is removed the wood is in a half-matured state, so roots readily; hence with less stress or weakening effect it commences upon its new life in February, with increased light and other conditions conducive to plant growth. Far more important than all this is the fact that in March, when the perpetual carnation is in the height of its vigour, the young plants are in 4in. pots ready for their first stopping, and instead of making three or four breaks, as in the case of the autumn cutting, it comes away with at least six growths, some of which are fit to stop for the second time before June.

I believe in course of time that January cuttings will become more and more popular, thus preserving the constitution of the varieties because, all too often, autumn cuttings are removed from plants which flowered throughout the previous autumn, winter, spring, and summer, the cuttings being taken when they are in an exhausted state, at the end of their life precisely when they are unfit to reproduce their kind. The result is indifferent growth, and still more unsatisfactory blooms, both as regards colour and size.

Of course, you can continue propagating during February and March, and personally, I would prefer a March cutting to an October one, and January cuttings, to my mind, are superior to all others. The value of selecting only the correct cuttings from selected plants is becoming more and more apparent to all, for these alone can produce good flowers.

Another important point is the conditions under which the cuttings are rooted. Too high a temperature is unnatural and unduly excites the cutting, whereas too low a temperature places an undue strain upon it. The best temperature for propagating are a bottom one of 55 degrees, and a top one of 45 degrees, and if the cutting is potted up as soon as rooted it will lose none of its vigour.

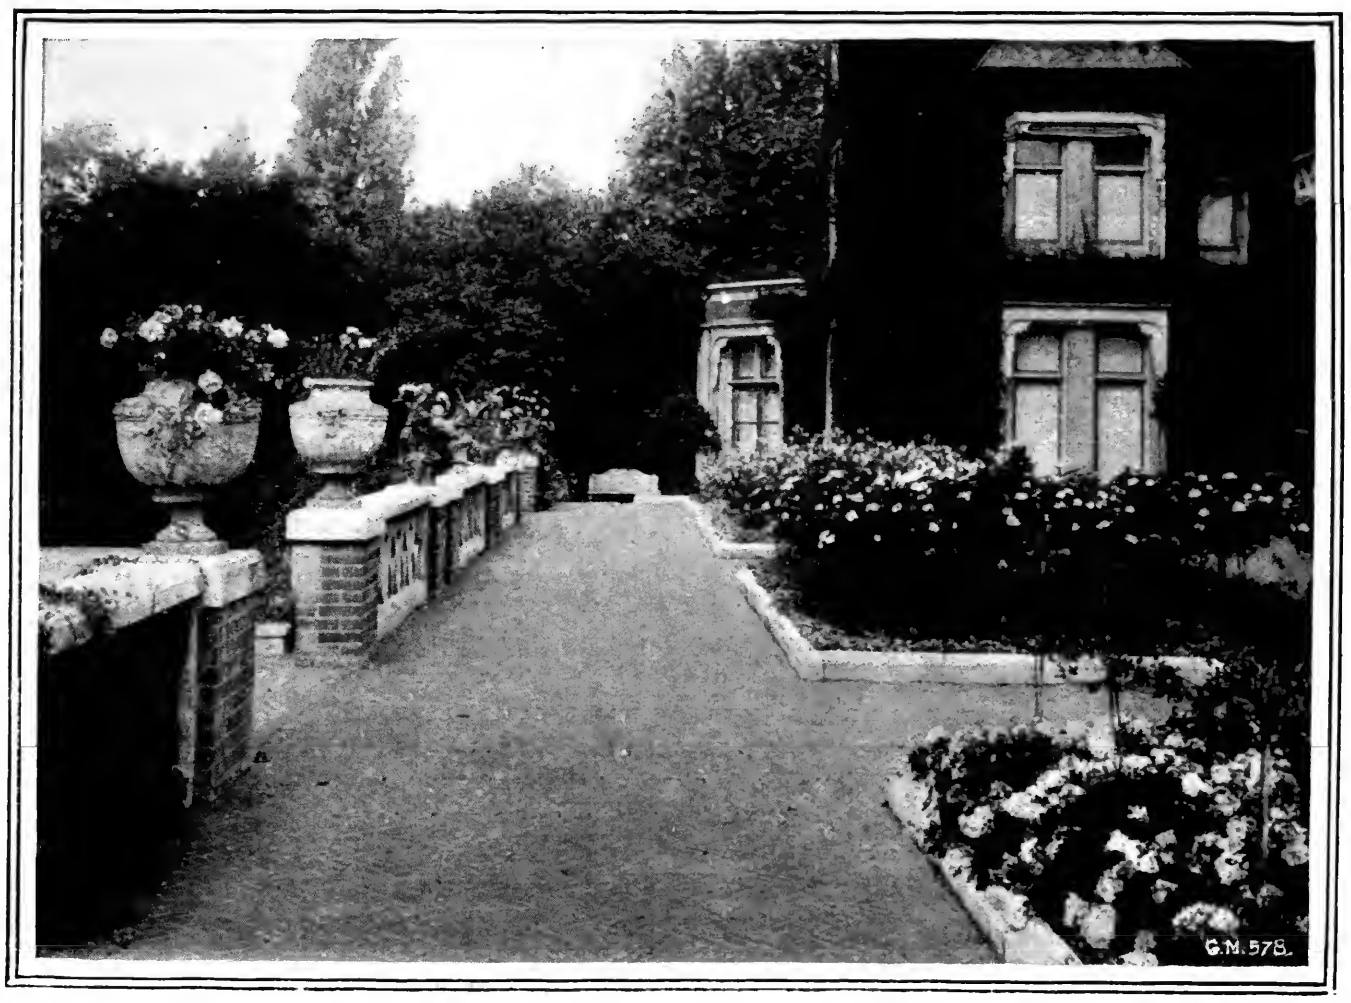
MONTAGU C. ALLWOOD.

Hayward's Heath

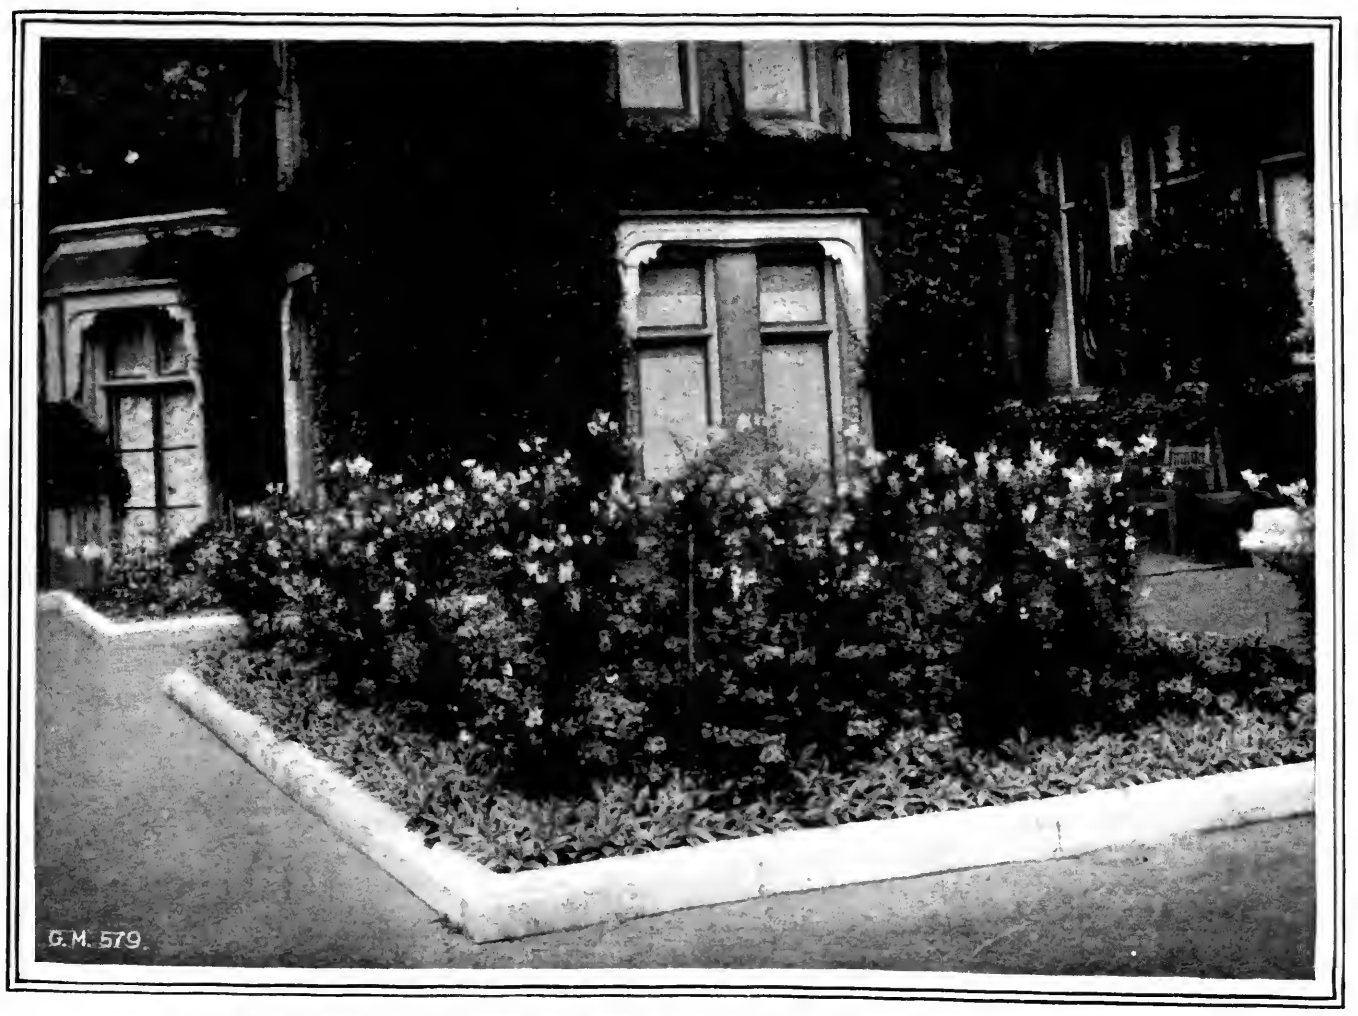
PREPARING FOR SUMMER BEDDING.

The prominence given to parterre planting with subjects of a half-hardy character, both in gardens of a private or public character, invests this branch of gardening with more than ordinary interest, and to those upon whom the arrangement devolves, its importance gains in interest from the fact that preparation for another season must be commenced early in the year. It is the general practice to develop this style of gardening under conditions that are severely formal, and usually in positions in front of, or in close proximity to the mansion; hence it follows that an arrangement that is continually under view must be elaborated with more than ordinary care. In some gardens the floral scheme can only be seen at some considerable distance, so that, to be effective it must be carried out on fairly broad lines, a result most readily attained by the simple combination of a few well-chosen subjects, in preference to any elaborate scheme involving the use of great variety.

A striking feature with present-day "bedding" is the sharp contrast it offers to, in its reaction from "carpet bedding," with its general feeling of stiffness and almost uniform flatness. To-day we employ two distinct types of plant. With one we obtain a groundwork or carpet to the bed, while the other is employed to secure height, an arrangement that admits of infinite latitude in treatment, and when successfully applied is, in the best sense, decorative, even in the case of plants trained in pyramidal or standard form. A certain freedom of growth is admitted, so that the artificial character does not obtrude itself, and the natural beauty of bedding plants is disclosed to a marked degree. The kinds of plants employed varies according to locality and the season during which they are expected to give the maximum display. In the southern and favoured parts of England, many tender subjects can be relied upon, that in the Midlands and northern parts of these islands give but indifferent results.



A TASTEFUL ARRANGEMENT OF TENDER PLANTS IN SUMMER AT COOMBE COURT.



A CHARMING COMBINATION OF SUMMER FLOWERS.
The tall plants are Swainsonia galegifolia alba, and the carpet of flowers and foliage is formed with Pelargonium Souv. de C. Turner and Veronica Andersoni variegata.

Chief among the most reliable subjects for bedding as tall plants, either pyramidal or standard trained, is Pelargonium Clorinda, a hybrid form with scented, rugose leaves and pretty bunches of deep pink flowers, carried all through summer. It is exceedingly vigorous in growth, and makes handsome standards in nine months from the cutting. Heliotropiums require longer to develop as standards, the best varieties being President Garfield, Lord Roberts, and Dr. Jeulin. Swainsonia galegifolia alba is one of the lightest and most graceful of summer plants, the pure white flowers being admirable in contrast with flowers of a deep pink or crimson shade. Cuttings of the previous autumn give plants a yard high by the following June. Where larger specimens are required it is desirable to use plants of two years' growth. Lantana delicatissima rivals the preceding in gracefulness, and introduces a distinct colour in bedding. Being a woody shrub, it is comparatively slow in growth, and where large plants are required, two seasons are at least necessary to secure this. Cuttings rooted in autumn produce nice bushy plants that are excellent to employ as groundwork; it is exceedingly free in flowering and always effective in autumn.

Plumbago capensis, for its unique shade of lavender flowers, that are most freely produced in autumn, is more a subject for favoured localities and warm seasons, as under adverse conditions it generally grows rank in wood and sparse in flower. Most popular of all, for tall pyramids, are the ivy-leaved forms of pelargonium, as they are exceedingly rapid in growth, brilliant in colour, and effective from May till November; Mdme. Crousse, pale pink; Galilee, soft rose-pink; Her Majesty, salmon; Souv. de Chas. Turner, rose-crimson; and James Hamilton, almost scarlet, are the most distinct and reliable varieties. Fuchsias lend themselves for standard work, as the pendulous flowers are then displayed to the best advantage. Charming is a reliable variety, with carmine and purple flowers, Alice Hoffman, has carmine and white semi-double flowers, and Sunray with tricolour leaves is valuable in contrast.

Calceolaria amplexicaulis, with large, soft lemon-yellow flowers, is a valuable asset in bedding, as it readily produces pyramids up

to four feet in height, and Streptosolen Jamesoni, an old greenhouse shrub, with huge-branched heads of rich orange flowers, is most effective when associated with lemon, lavender, and blue flowers.

Plants of an intermediate height are represented by Marguerites Queen Alexandra, Mrs. F. Sander, and Boule de Niege; cuttings of these taken in autumn and grown on under glass during winter, form large plants for placing in the open during May and June; dwarf cannas come under this section, their richly coloured flowers of many hues, in conjunction with their bold foliage, being most effective in mixed arrangements. Leucophyton Browni, when grown into dwarf pyramids, is valuable as a contrast, owing to the striking, silvery-white foliage; it is readily propagated by the growing points in autumn and spring, and Kochia trichophylla for its pale grass-green, feathery leaves, that glow a ruddy crimson in autumn, being distinct from all other bedding plants, its effect is always readily apparent. The last-named is an annual, easily raised from seed sown in March. Among low-growing bedding plants the variety is exceedingly great, and is, to a large extent, dominated by pelargoniums of the ivy-leaved and zonal sections. Of the latter section the most popular variety is Paul Crampel, with bright crimson-scarlet flowers. A distinct sport from this variety has flowers of a bright salmon shade. Of older single-flowered varieties, Henry Jacoby, crimson; Master Christine, pink; Robert Hayes, pearly-pink; Queen of the Belgians, white; and Vesuvius, scarlet; and of double varieties, Hermoine, white; Improved Raspail, orange-scarlet; and Mrs Lawrence, pink; are all effective and reliable. Of the ivy-leaved section those previously named are best. Achievement might be added, as it is neat in habit and equals any in the display produced.

Verbenas rival pelargoniums for a brilliant effect. Miss Willmott, pink, and Princess of Wales, dark blue, are two of the best; cuttings of the first-named are best struck in July, and, if potted up and grown in the open on a cinder bed, they make first-rate stock plants, not liable to be attacked by mildew. Princess of Wales may be struck in the ordinary way now, as mildew does not attack it to any serious extent. Verbena venosa is distinct from the others, having rich purple flowers; it is best grown from seed sown in August and grown on steadily till planting-out time. Iresines Herbsti and Lindeni and Coleus Verschaffelti are much in request for their highly-coloured foliage. Cuttings strike readily at the present season, from which cuttings are readily obtained in spring. Where tall plants of these are required, earlier propagation is advisable, and the plants grown on steadily without check, until the desired height is obtained. Numerous other subjects are in request for summer bedding, but their propagation does not materially differ from those already enumerated, which, with few exceptions, require the protection of glass, and a certain degree of heat, during winter. Plants like pentstemon, antirrhinum, and Veronica Andersoni variegata, are also propagated by cuttings in the autumn, but these only require the protection of hand lights to render them safe from frost. Stock plants of bedding subjects are best kept on the dry side during November, December, and the early part of January. It serves no useful purpose to force growth during that period, while plants over-watered are generally weak, and rarely produce satisfactory cuttings.

THOMAS SMITH.

Coombe Court Gardens.

THE JAPANESE GARDEN.

In pressing the Japanese ideal for what it is worth, let me say at once that I am not impelled by any idea of deficiency in English gardening. Not at all! My one aim and object is that the manifold art and peaceful beauty embodied in the Japanese garden should be utilised in this country as a branch of garden art alone.

The possibilities in either case are vast. The changing effects are endless, the whole is one interwoven picture of contrasts and harmonies of peaceful beauty and inspiring effects. The possibilities of the garden are utilised in such a way that one can only marvel at the garden values brought to light by following the Japanese ideals. That the Japanese are expert copyists, such as few English garden workers can equal, is without doubt. They will reproduce in the garden "a view of Fuji-Yama, even to the snow-capped peak," "a vista of Matsushima with its pine-clad islets, set in a summer sea," "a rocky waterfall, with darkening, distant trees and a massing of azaleas and maples on the hill-side," as one might see round Nikko, or "a miniature River Sumida, with the cherry orchards clustering on its green sloping banks," or aught else that the Japanese eye can see, or the Japanese heart desire.

But this is not necessary to the English garden-maker. We do not need these reproductions. What we do want is to get the ideals of this artistic race into our minds and apply them to the garden or gardens which we may have the opportunity of developing. The ideals which will help us to give every garden feature its true proportions will assist us to make the garden a haunt of pleasing diversity, a home of repose, a place to be remembered for its charming features and its telling effects.

Now to the point. To the utilisation of a correct ideal. There are two great essentials—rocks and water. Between these two one must evolve the main part of his picture. This requires "eye work" and "brain work." A good survey of the space available, and then a thoughtful consideration of how to make the most of the picture.

The "natural ideal" must predominate. If you have hill-side or mountain cliff, river bank or ferny glen, they must be where they would be in Nature, and be planted up with just those plants and trees that one would expect to find in such positions.

Then, again, everything must be proportionate. The rocks used must be of sufficient size to create a hill-side effect, otherwise all values will be lost. The stepping-stones must be stepping-stones, not pitfalls for the unwary. Yon distant hill must appear as a "distant hill." It may be the highest point in the garden, but it must not "predominate over the entire scene." Let it rise, if possible, at the back of lower hills, and be covered with low pines, or other mountain trees.

With the pools and water-courses, let them be in accordance with the arrangement of the ground around. A deep, slow-moving stream, or large lake, is only possible where one has an open expanse of ground. Amid rocks and sharp hills the streams will be small but quick in movement, and the pools comparatively small, and here and there flanked by rocks. A typical mountain pool, and not a marshy mere, is required for such a position.

If a jungled dell is desired keep it on one hand of the water-course, where the ground does not rise very quickly. A low depression with gently sloping banks would be ideal, and one could group bamboos, eulalias, glyceras, irises, etc., in a delightfully informal manner.

Bridges and Tea Houses, etc.

Here, again, warning is necessary. In the matter of garden bridges and tea houses the effect is often spoiled by elaboration. One should err, if he err at all, on the side of simplicity. A plainness of material, and softening, unobtrusive outlines should be the aim in either case. Here rough material in an artist hand is far more effective and harmonious than the more finished work of the expert mechanic. Bear in mind that all garden woodwork and garden houses must exist for a purpose. Do not put them in merely for the sake of "filling up the picture." Your bridges must exist to carry you over a waterway, but if the space is not sufficiently large to warrant a bridge, then a causeway of stepping stones would be more in keeping in providing a means of crossing the water dry shod.

The tea house should (if required) be made in proportion to the size of the garden, and its formation. Let it be overhung with wistarias or vines, or clematis, or other suitable climbing subjects. A bower of beauty!

"A Garden of Changing Scenes."

The present craze for stone lanterns is, perhaps, more a passing fancy than anything else. In it there is a certain danger of over-doing this phase of ornamentation, and producing a crude effect. Properly placed, a stone lantern is an asset to the informal garden. A low valley-lantern on a water-worn rock by the streamside, with a few hydrangeas, irises, or other subjects grouped at the sides, may well be effective, or a taller lantern of Kasuga pattern, near a grove of bamboos or a wide-flung pine, would give equal value. But beware of repetition and crude bizarre effects.

With my concluding notes I desire to draw attention to the value of diversity and changing effects. Half the value of any garden, and more than half the charm, is lost if you can see it all at a glance. One or two rock gardens recently designed with a view of producing a Japanese effect fail at this point. You can see the whole from the entrance! It is much more desirable, more pleasing, to wander through a garden where fresh beauty and new scenery confronts one at every turn. The pleasure of a hidden lily pool, an iris swamp in a depression, a range of stepping-stones through a waterway where one least expected them, a tea house half-hidden in a bower of greenery, an unexpected view through a hillside opening—these and many others are what constitute the charm and delight of a garden. Diversity and exquisite touches of natural beauty tell more than anything else.

Then the value of an ever-changing landscape! This is a strong point of mine in garden-making. By utilising the beauty of bulbous plants, flowering shrubs and trees, perennial plants, and waterside subjects, one can arrange a series of garden pictures which will carry one from beauty to beauty throughout the greater portion of the year. Especial displays of given subjects may occur by devoting space and attention to lilies, pæonies, irises, wistarias, azaleas, chrysanthemums, maples, or such other subjects that one might particularly desire. The idea is of distinct value. One should utilise it to the full.

EARLY VEGETABLES FROM SEEDS.—III.

Peas.

Of all vegetables raised annually from seed perhaps none is more appreciated than the first dish of peas. At one time good peas in May realised high prices, as much as 1s. 6d. to 2s. per pound in the pods, but in recent years larger supplies have tended to reduce the price. Some seventeen or eighteen years ago, Mr. Norman Davis, one of the earliest cultivators of peas under glass for market, secured handsome returns when he commenced growing high-class culinary peas in the huge house in his nursery at Framfield.

The best results are obtained by sowing in the natural soil of the floor of a cold house, the soil having been previously double-dug and manured. Where lime is deficient, a liberal dressing of powdered chalk should be applied, or a smaller quantity of freshly slaked or even air-slaked lime.

I find, however, as I believe Mr. Davis did, that where the peas are grown annually in the same soil, no matter how thorough the preparation, the crop after a time falls off, and the individual plants are liable to become affected. Eel-worm also makes serious inroads on the energies of the plants, so that it is well to give the soil a rest every other year. I might say this deterioration is less marked on heavy than on light soils.

Varieties of moderate height, as Gradus, Early Giant, and Ideal, are most suitable. Ideal is the earliest pea I am acquainted with apart from the very dwarf peas. It bears at a lower node than other peas of the type. In structures with sufficient head-room, Duke of Albany, Centenary, and Harvestman may be included to prolong the supply. Two good second early pears of moderate height are Superlative and Discovery.

Selection of stock is important in the case of peas in the open, but doubly so when the seed is required for cultivation under glass. I know of no vegetable, excepting perhaps beet, which deteriorates so rapidly under indiscriminate methods of seed-sowing as the pea. The high price of good stocks is well repaid in the increased return.

A short time ago we had a number of rows of Duke of Albany grown from seed saved from the crop of one row. One-half of the rows was grown from seeds saved from selected pods, and selected plants bearing in pairs. In this set every pod was rejected which had not produced ten peas per pod. The remaining rows were grown from seed harvested after the selected pods had been gathered.

No one would have taken them to be the same stock, although every plant in the first instance sprang from seeds of one pod, and only a year or so before. Unceasing selection and re-selection has to go on if the standard is to be maintained, and hence the difficulty—the impossibility—of placing large quantities of high-class seed peas on the market at a low price.

We make our first sowing in a span house in the last few days of the year, the rows being three feet apart. Tall varieties will, of course, need more space. Sow thinly in drills six inches wide, and the individual seeds two and a-half to three inches apart, and cover half an inch deep. We usually rake in a dressing of superphosphate and wood ashes previous to drawing the drills.

The spaces between the rows are filled up with three rows of a small cabbage lettuce pricked out about the middle of January from seeds sown in the last half of November in a house with a night temperature of 45 to 55 degrees.

Those who have pits and frames sufficiently deep may sow dwarf kinds in rows eighteen inches to two feet apart or the seeds may be sown in pots, and subsequently planted out in the frames.

For planting outdoors I find the best time to sow is about the first week of February, sowing six or seven seeds in a large 60 or 54-sized pot. If sown earlier, the plants are apt to become too large before the weather permits safe planting out, except it is in those parts of the country where the winters are comparatively mild. The balls may be planted out unbroken one foot apart. Unless division of the roots is done very carefully, and the weather is favourable, the method of placing the plants out separately a few inches apart is liable to give the peas a serious check.

Peas in the early stages will not be hurried, and if growing in heated houses, only sufficient heat should be applied to keep out frost. Ventilation, too, must be attended to, or a close, damp atmosphere will bring about mildew and mould.

Turnips.

These are not in great demand, but a few may be sown in drills, six to eight inches apart toward the end of January or early in February, and intercropped with radishes. Thin when large enough to six or eight inches apart. The smaller distance is sufficient for the French Long White, which is the best for the earliest sowing. The February sowing may be the Red and White Milan, which need a little more space. The beds for these would be similar to those used for lettuce at this date. Turnips are sometimes disappointing. Unless carefully ventilated and watered, they are apt to bolt in the early sowings.

Vegetable Marrows.

Where sufficient room exists a few of these may very well be grown if variety is wanted. There appears to be a fair sale for them in June. The bush kinds are the best for frame culture. Seeds can be sown early in February in a mean temperature of 60 degrees in single pots, and the plants placed out at the end of the month on a mild hotbed, one to a sash, in a heated pit, and planting in good soil. The flowers may need fertilising at this time of year, as is sometimes the case with later sowings planted outside with some protection early in the season. Bumble-bees appear to be the chief agents in pollinating the flowers, and there are few of these about in the spring.

From want of oversight, it happens sometimes that all the earliest embryo fruits rot for want of attention in the way of pollination. The variety Tender and True is as useful a vegetable marrow as any to grow for the earliest supplies.

Reading. F. DREW.

ERICA LUSITANICA.

This erica, better known as E. codonodes, is undoubtedly the most beautiful of the tree heaths, and is especially valuable from its habit of flowering in the depth of winter. Before the old year has departed in Devon and Cornwall its earliest buds begin to show white, and before the conclusion of January, in the south-west, it is generally in full flower. Large specimens present a charming sight when in full blossom, appearing from a little distance like tall pyramids of white, faintly tinged with pink, six feet or more in height. The character of growth of this heath is erect, and the upright sprays, studded with a profusion of drooping, white, elongated bells, have the appearance of snowy plumes when cut. The individual blossoms, when closely examined, show a suspicion of pink, but this is scarcely apparent when they are seen in a growing bush. Since it is a native of Southern Spain and Portugal it can hardly be considered absolutely hardy, though to the south of London it is rarely injured by frosts, and in the south-west grows luxuriantly.

Though delighting in a peaty soil, it will, like rhododendrons, azaleas, and kalmias, flourish in a sound, porous loam that contains no lime. In some gardens it increases freely by self-sown seedlings, and on the embankment of a certain little Cornish station there are numbers of plants that have sprung from seed. Self-sown seedlings are cleared away when they threaten to crowd other plants, but they transplant easily, and soon almost rival their parents in size. It will occasionally attain a height of nearly ten feet, with a diameter of about four feet, if left untouched, but if it is annually cut hard for flower sprays it assumes a dwarfer habit, a bush in a neighbouring garden that has been treated in this manner for years now being about five feet in height and six feet across. Its foliage is of an extremely rich green, and the flowering season is a very prolonged one, generally lasting for three or four months. Erica mediterranea and E. arborea also do well in Devon and Cornwall, one of the largest specimens of the former being about eight feet in height, and fifteen feet through, while E. arborea considerably exceeds even these large dimensions.

WYNDHAM FITZHERBERT.

South Devon.

Clerodendron fallax.—The plants that flowered in autumn and have been reduced to the well-ripened wood, will by this time each show several young growths. These, if taken off with a small heel when about 3in. in length, inserted singly in small pots containing sandy soil, and plunged in the propagating frame, will be found to root readily. Shifted on into 5in. pots when nicely watered, they will provide a useful early summer batch. When grown from cuttings they rarely attain so high a state of development as well-grown seedlings. A batch for autumn-flowering may be raised by sowing seeds at once in a shallow pan. We prefer to save our seed, and, having carefully ripened it, store it in a small box filled with dry silver sand. Before they are sown the seeds are soaked in tepid water until they commence to swell when they are carefully dibbled in a seed pan about thirty in each. A compost consisting of loam, peat, leaf-mould, and sand, is used in filling the seed pan. Place a sheet of glass over the pan and shade until the seedlings appear, when they will require a light position. When of a size convenient for handling pot off singly, using a rich compost, and continue to grow near the glass in the stove until ready for the final potting. H. PRIME, Hatfield House Gardens.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

DECIDUOUS DENDROBIUMS.—The early-flowering plants, both of species and hybrids belonging to the deciduous section of dendrobiums, will now be pushing their flower buds from the sides of the matured pseudo-bulbs. In private gardens, where a succession of flowers is required through the winter and spring months, these plants are exceedingly useful, and by taking a little care in selection, they may be bloomed in batches, and a continuous supply of flowers obtained. It is a great pity these dendrobiums are not so extensively grown, as was the case a few years ago. It generally follows, however, that where plants cease to be fashionable, the opportunity is given for procuring the most useful kinds for a modest outlay; and where facilities are available for cultivation, it is desirable to procure a varied collection of the better kinds now the market is favourable for the purpose.

FLOWERING OF DENDROBIUMS.—In taking plants from their resting conditions, it is advisable to avoid any sudden excitement in the matter of temperature and treatment. It is desirable to select for starting into growth first those plants that have the flower buds well advanced. If possible, arrange the plants that are showing their flower buds separately for the first batch, have them removed by degrees into the warmest house, and place them in a position where they may obtain the full benefit of the available light. Supply water to the roots sparingly until the flowers commence to expand, and then more liberal treatment may be given. Care should be observed to see that the water is a few degrees warmer than the temperature of the house.

REPOTTING DENDROBIUMS.—Any repotting necessary may be attended to as the plants pass out of bloom. The advancing young growth emits new roots early, and to avoid injury to these potting should be attended to at an early period. Deciduous dendrobiums do not require a large bulk of potting material about their roots. Good fibrous peat and chopped sphagnum moss, with sufficient sand and broken charcoal intermixed, forms an excellent compost. This should be pressed firmly about the roots. Neat stakes to secure the pseudo-bulbs in position should be fixed where necessary and desirable. In the early stages of growth watering must be carefully done; considerable advantage will be found from syringing or spraying overhead in bright weather.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

EUPHORBIA FULGENS (JACQUINIÆFLORA).—This beautiful winter-flowering subject, now at its best, may be kept so for some time in a temperature of about 60 degrees, the atmosphere fairly dry, and the plants kept rather dry at the root. Plants from which the flowers have been cut should be examined weekly for the purpose of ascertaining the condition of the soil with respect to moisture, applying just sufficient water to prevent the stems shrivelling. This will ensure their becoming well matured and furnishing cuttings that will root fairly easy from the early part of March.

POINSETTIA PULCHERRIMA.—As the bracts of the poinsettias are cut the plants may be assisted in the ripening process by gradually reducing the supply of water at the roots, until they have lost their leaves. They may be stored in a dry position in a house in which a temperature of not less than 55 degrees is maintained.

SEED SOWING Stove plants grown for their flowers, which may be raised from seeds sown now include Amaryllis (Hippeastrums), Exacum macranthem, gloxinias, and streptocarpus. Among fine foliage plants that can be readily raised from seeds at this season are Asparagus Sprengeri, A. plumosus, A. decumbens, and others, grevilleas, and Rex begonias. A mixture of loam, two parts, leaf-mould one part, and peat one part, with sufficient sand to keep the whole open, will be suitable for filling the seed pans for all the kinds. The pans or pots should be clean, well crocked, and filled to within half an inch of the top with the compost. Water well before sowing the seed, which should be scattered evenly over the surface, and just covered with finely sifted soil. They may be plunged in the propagating pit, or in the hotbed material within the cucumber pit, covering with sheets of glass, and shading until the seedlings appear.

PROPAGATION BY CUTTINGS.—As shortly the propagating pit will be constantly filled it is advisable to strike as early as possible good batches of cuttings of such useful and easily-rooted plants as Panicum variegatum, selaginellas, and fittonias. Coleus will be found to root readily.

SAINTPAULIA IONANTHA.—Propagation of this beautiful and useful little plant is readily effected by means of leaf cuttings. Plants raised from leaves inserted at this season will produce a fine display during the summer months, given fair treatment. Leaves should be broken, not cut, from the plant, with an inch or so of the petiole, and inserted in any light, open place within the stove in a little sandy soil. By occasional light damping they will, in a short time not only have become rooted, but nice little plants will have been formed. Carefully pot them, using small 60's and a sandy compost, and reduce to a single crown. A place near the glass will suit them best, and, as with most newly-potted plants, great care should be exercised in the use of the watering-pot. Few plants will succeed if once over-watered.—H. PRIME, Hatfield House Gardens.

FRUITS UNDER GLASS.

PINES.—The few private growers who still cultivate these fruits successfully do not look to these calendars for instructions, so only a few hints are necessary as to their cultivation. The first batch of Queens should now be started to obtain ripe fruits in May and June with a bottom heat of 80 to 85 degrees. No advantage is gained by exceeding the latter figure, but the delicate roots may easily be injured. Those who have the beds heated with hot-water pipes have nothing to fear, as the temperature is easily regulated, but the uncertainty of fresh tan or leaves is very different, and great care and attention is necessary to maintain as steady a heat as possible. The beginner will see from these few remarks that success or failure turns upon a brisk, steady bottom-heat being maintained. Divest the plants when removed from the resting bed of a few of the short bottom leaves, and loosen the surface soil, and top-dress with good loam from the surface, which cannot well be made too firm round the collar.

EARLY VINES in pots and borders will now be found in various stages of growth, and the different operations must be attended to at the proper time. Disbudding and tying down will soon require daily attention, and later each shoot must be pinched at the second or third leaf beyond the bunch according to space. Syringing should be discontinued when all the buds have started, and the walls, paths, and borders lightly damped about three times a day. The temperature of houses that are closed now may range from 45 to 48 degrees, when in free growth 58 to 60 degrees at night or a little higher when mild, 70 to 75 degrees by day, and 80 degrees after being shut up. A little air should be admitted at all times, or at least should be admitted on all favourable occasions.

LATE VINERIES.—If all the grapes have not been cut, no further time should be lost in cutting the bunches with a piece of lateral, and placing them in the grape room with the end of the latter in water; otherwise there is danger of the vines bleeding later when pruned. Dress the wounds with styptic before the vines receive any water, and keep the houses dry and cool after cleansing until the end of February or March.

POT FRUITS.—Stone fruits of all kinds do well in pots when judiciously managed, and by forcing a score or two of the earliest sorts, the closing of permanent houses may be deferred. January is a good time to start the orchard house peaches, nectarines, pears, apples, plums, and cherries, commencing at the warmest end with peaches; of course, where separate departments can be devoted to the different varieties so much the better. The chief points are light, well-ventilated houses, healthy trees, avoidance of high and close temperature in mild weather, or falling below 40 in severe Weather.—F. JORDAN, Water Priory.

THE FLOWER GARDEN.

DELPHINIUMS.—In all well-arranged herbaceous borders, perennial delphiniums form a strong feature early in summer, and are of great beauty. An autumn display is somewhat uncommon and most attractive, and is by no means difficult to attain. For this purpose they require treating similarly to some annuals, and if well grown 95 per cent. of the plants will produce spikes during August and September of the first year that will range from three to six feet in height. The seed should be sown now in pans, and be placed in a gentle heat to assist gerination. When the seedlings are large enough, prick them off three inches apart in boxes containing about four inches in depth of rich soil. Grow them on in a moderately-heated pit in a light position until well rooted, then transfer them to a cold frame, which should be well ventilated on all mild days. Towards the end of April they will be ready to plant out. Prepare the ground previously by digging it deeply and adding a heavy dressing of well-decayed manure. Allow twelve inches each way between the plants, and water them well in if the ground is at all dry. The after treatment consists chiefly of frequently moving the soil with a hoe, and should a very dry spell be experienced, an occasional soaking of water will be very beneficial.

STOCKS OF SUMMER-BEDDING PLANTS must be carefully examined, and if there is a likelihood of any shortage occurring, immediate steps should be taken to make up the deficiency. In many instances this can be overcome by placing all available stock plants into a moderate heat, and so encourage them to produce young growths for the supply of cuttings. Heliotropes, lobelias, pelargoniums, salvias, etc., started now will give cuttings that will root most readily. Young plants of heliotropes and fuchsias that were rooted in August, which are intended to be grown on to make standards or pyramids, will now be growing freely in 6in. pots, and an effort should be made to maintain a vigorous growth without a check. Artificial manure and soot-water applied weak and often will greaty assist them. Pinching the lateral growths and tying in the leading shoots must be attended to regularly. Frames and pits containing calceolarias, pentstemons, violas, etc., will now need increased attention, and every opportunty should be taken to admit air whenever favourable, avoiding cold draughts. As growth becomes active amongst the various inmates, most of them will require pinching to induce side and base growths to develop.—T. B. FIELD, Wych Cross Place Gardens.

SHRUBS FOR WINTER EFFECT.

In the formation of shrubberies, or in adding to existing ones, consideration should be given to species and varieties that contribute, either by their flowers, fruit, leafage, or stems, brightness to the scene in winter and the dull season. It may be suggested that subjects that answer to this description be concentrated in such a position that they can be seen from the windows of the house, and certainly a cheery outlook could be created in this way.

In addition to the various conifers with coloured foliage, aucubas, the hollies, which illuminate the landscape with their fiery fruits, and many other subjects may be pressed into service. Amongst deciduous subjects we have nothing to compare, as far as brilliance and freedom of flowering is concerned, with Jasminum nudiflorum, which with the advent of winter hastens to clothe itself in pure gold. It is perhaps seen to the best advantage against walls, but in the shrubbery, provided it is sheltered by shrubs of larger growth, it will prove free in flowering, and highly attractive when in bloom. Almost before the old year has resolved itself into a memory the brilliant Pyrus japonica becomes a mass of tiny scarlet balls, and everybody knows how it hastens to expand and exhibit its ruddy colouring if the weather remains open. It is very generally employed in gardens as a wall shrub, but grown in bush form in shrubberies its value is clearly demonstrated. Hedges are formed of this plant in the county of Devon, also Cornwall, and what a beautiful effect they produce over a long period. The laurustinus is essentially a winter-flowering subject, and renders good service if sheltered from north and east winds, and is second to none for our purpose. Mature and green fruits, also flower buds and expanded blossoms, can be found upon the Strawberry Tree (Arbutus unedo), and its handsome hybrids, throughout the winter. In consequence thereof they are splendid additions to the list of winter subjects, and several good specimens should exist in every shrubbery.

Very effective is Pyracantha Lelandi with its wealth of scarlet berries, and it looks well covering a rustic pole or old tree stump, while Cotoneaster Simmondsi forms a handsome bush. Several of the honeysuckles possess the temerity to bloom while the year is yet young, and the offering they bring is characterised by delicious fragrance, the same remark applying to Chimonanthus fragrans. The Glastonbury thorn and the almond trees must find a place; the first-named is erratic in its behaviour, and at times fails to maintain its reputation, while the lovely inflorescence of the almond tree, borne in prodigal profusion upon the leafless stems early in the year, are often badly hit by frost.

The sea buckthorn and Skimmia japonica extend the list, and the more choice elæagnuses supply coloured leafage, as does also the gold and silver ivies, which should rise in column form trained upon large tree boles. I have yet to call attention to species of rhododendron which exhibit their charms early in February, namely, Nobleanum, præcox, and altaclarense. With regard to these it is necessary to add that if it is seen that severe frosts are likely to occur when the flowers are expanding, protection should be given by means of bracken or St. Petersburg mats carefully placed over the plants at night. Daphne mezereum will diffuse fragrance, as well as give colour to the shrubbery, while Garrya elliptica and Clematis calycina are charming additions.

We possess splendid material in the hardy heaths for beds and the front of shrubberies, and if planted in the latter, in groups of a dozen or more of suitable species, present a very cheery and effective appearance. Shrubs with coloured stems play an important part in the decorative scheme, and amongst these Cornus alba is a good example in bright red. The stems of Salix vitellina are of a golden hue, while those of S. argentea and S. daphnoides are white and bluish respectively. The "Lady of the Woods," otherwise the birch tree, should be represtnted on account of its glistening white bark; also Rubus biflorus, which has a decided glaucous bloom upon its stems. Lastly, great clumps of the Christmas rose should be encouraged, through the protection of the surrounding shrubs, to yield a succession of bloom, while great colonies of winter aconites and snowdrops, primroses and violets, are indispensable in the formation of this interesting feature, which may be termed an outdoor winter garden.

WALTER H. AGGETT.

CHOICE ALPINE FLOWERS.

From among the multitude of good alpine flowers now being placed before the public we may well select a few for notice as excellent and choice plants, not necessarily new, yet not common in gardens, and, notwithstanding this, not expensive to purchase.

Æthionema grandiflorum.

In this plant we have one of the easiest and freest of all the æthionemas, or Lebanon candytufts, refined sisters of the iberises, most of which have pretty blue-green leaves and nice spikes of flowers. There are some of special beauty, which may be reckoned as dwarfer and choicer than Æ. grandiflorum, but for general effect this carries off the blue ribbon for its value. Taller rather than most of its allies, it sometimes makes a nice spreading bush about a foot high, and yielding for a long stretch its nice rose-coloured flowers It is among the hardiest of the race, but, like its charming sisters, loves sun, lime, and a dry place. It may suffer from wet in winter, but in summer, when once established, Æthionema grandiflorum apparently delights in all the sunshine and almost torrid heat of our hottest and driest summers—all too few indeed, but welcome to this plant when they do come.

Alyssum montanum.

We observe a few of the alyssums or madworts in many gardens, and too much space is frequently devoted to the glowing mounds of yellow given by Alyssum saxatile, to the exclusion of some of the daintier and fascinating, though smaller and less effective sister flowers. A plant one only comes across now and again is A. montanum, the Mountain Madwort, which is, perhaps, the best of the smaller and more truly alpine species. Those who know it not may possibly realise something of its beauty when they are told that it is a charming hoary-leaved little plant, growing some three inches high, and bearing a host of its small yellow flowers, which have the added attraction of sweet scent to delight the olfactory organs of those who take pleasure in the fragrance of flowers—and who does not? Alyssum montanum need give little trouble if planted on a sunny slope and in a soil with a modicum of lime, if possible, although this is not essential. A packet of seeds, purchaseable for a few pence, will give plants enough and to spare, or small ones may be purchased from hardy plant dealers at a low price.

Silene Elizabethæ.

One wonders why Silene Elizabethæ always remains so scarce, and why it is so seldom to be met with in nurseries. Probably we may see it oftener nowadays when the moraine, large or small, is becoming indispensable to every good rock garden. It is most at home there, especially where there is some lime intermixed with the gravel or stone chips. The free drainage appears to suit this catchfly exceedingly well, but those who lack a moraine will not be disappointed with it provided they will plant it in stony parts of the rockery, where it is exceptionally well drained. One would expect a silene like S. Elizabethæ to be a craver for sun, but in the moraine it will flourish with either sun or shade, while in other parts it evinces a preference for a cool place. As for the plant itself, it has been well described as like a clarkia in its rose-coloured blooms, which grow on arching stems some six inches high, reared above the glossy, nice green leaves. It can be raised from seeds, not often offered, by the way, or by division. This Tyrolese species can be bought for a shilling or eighteenpence, and the price is not too high to pay for such a charming alpine.

Douglasia vitaliana.

One wonders why such a charming alpine as this has so many aliases. We do not generally associate an alias with a desirable character when assumed by any of the human race, and even in the kingdom of Flora we hardly appreciate the plant which has a long list of synonyms. Few are fated to have so many as the one under notice, which has been bandied about by the botanists from Androsace to Aretia, and from Aretia to Primula, and from Primula to Gregoryia (I am not adhering to the precise order of the process), and is now, for the nonce, at least, dubbed Douglasia vitaliana. As such we are content to take it now. No choicer plant can well be in a rock garden than this. Where it does well, it makes a close, tiny carpet of soft, mossy-looking bright green, rather silvered leaves, which in their season, when the plant does well, are spangled with charming little yellow flowers. Now we are told that this likes limestone crevices in full sun. So it does, but these are not essential, and one needful thing is not always granted in artificial limestone rocks. This is moisture at the roots, and, sun-lover as it is, drought is hateful to this Douglasia. But by all means attempt this charming—nay, exquisite—alpine.

Mertensia echioides.

It seems but a short time ago that we were confined to some three of the taller, or border, mertensias, but now we have some dainty kinswomen for the rock garden, and these are of still greater beauty, and mostly of rare value for the cooler corner of the rockery. None can well be prettier than M. primuloides, which grows some six or nine inches high, and has neat little tubular flowers, that, like those of its taller sisters, change in colour from the time they open. Ruby, blue, purple, and intermediate shades are to be seen on these flowers, so that the plant, taking it all in all, is a subject which may and does command our highest admiration. As for its culture, it is not difficult, but it does not enjoy a dry, sunny place, and should be in a cool, peaty soil, or in good, though not stiff loam, in a shaded or semi-shady nook. Mertensia primuloides is one of the alpines we delight in as the year comes round.

S. ARNOTT.

ALTERATIONS.

It has been said, not without a considerable amount of truth, that the greatest pleasure of gardening consists in the making of alterations. I used to know an ardent old amateur whose enthusiasm was not lessened by the near approach of his tenth decade, who used to make a considerable number of alterations every year, though they were principally of a minor character, and his greatest delight was to take friends round the garden and describe what he had done, speaking with great gusto of the effects that would be produced in two or three years' time, and though he would sometimes admit that he might not live to see them, his keenness was not dimmed by the thought, and he had reason on his side, for do not actuarial tables tell us that even at the age of a hundred a man still has an expectation of more than a year's life?

Now this is not altogether the delight in change for the sake of change, as ladies sometimes change the position of a piece or two of furniture in a room, without any idea of improvement. It takes a long time to exhaust the possibilities even of a suburban rectangular back garden, and when people have lived in a place for twenty years they are sometimes suddenly seized with the idea of an alteration which is such an obvious improvement that they wonder how it is they never thought of it before. It is not only that ideas dawn upon us after this lapse of time which might equally well have come to us before, but our minds have been, or should have been, growing all that time, and our taste and our ideas of beauty developing, for when we cease to grow it is the near approach of the stagnation of all things. And besides the changes in our ideas there are changes in the garden itself, which make other changes inevitable, whether we will or not.

Of these many instances might be given, such as the decay or increasing size of trees and shrubs, the necessity of changing the positions of very old beds of roses, asparagus, and the like, besides the effect of our neighbours' building, tree planting, and so on.

All these changes need to be done at the right time, and in the right way. There are some homes without repose, where there is always some part of it in a condition of being cleaned or done something to, or where the inmates are always in haste to be doing something, either at home or out of it, with the result that there is a general atmosphere of unrest, and an entire absence of those features in the home life of the Arnolds at Rugby which made Thomas Carlyle describe it as "a temple of industrious peace." So, in many gardens, there is always a state of unreadiness for the inspection of visitors—a heap of rubbish to be burned or buried, a rockery in the making, an arch broken down and not yet repaired, and so on—with the result that the garden lacks what should be, next to privacy, the most precious feature of all gardens—the sense of repose, which makes the garden a place to dispel our moods of irritability, worrying, depression, and other conditions of mind, which, if we ever experience them, are best dispelled so quickly that they are a long time before they return to us.

In order that the making of alterations should not destroy this most precious feature of the garden, even temporarily, plans should be well matured before being put into execution. We expect to see our gardens in the making during the autumn and early in winter, and any muddle there may be seems rather in keeping with the season of whirling leaves and battered stems. An exception should be made, perhaps, in the planting of evergreen shrubs, which are not most successfully planted then as well as some plants. At this season we frequent the garden more for work than for repose, and the taking up of plants and the barrowing of earth and manure, do not spoil the harmony of the place, as the soil usually works so well that it seems intended by Nature that we should take advantage of the season for this work. In the spring there will not be that appearance of discomfort about unestablished plants, which need to be kept watered after a dry fortnight in April; they will start so well that they will make us forget the wild disorder a few months before. Nothing proclaims the thoroughgoing enthusiast so clearly as the use he makes of the month of November for works of this character. The half-hearted amateur, if he can even be called a gardener at all, wonders what interest there can be in a garden at midwinter, and what there can be to do then, but the other knows that it is the season for wheelbarrow, pickaxe, and spade, and the season of all the four when he would least soon be away from it, for there is more enjoyment and more real satisfaction in moving plants, renovating beds and borders, and making general alterations at that season than in any other part of the year.

ALGER PETTS.

THE AMERICAN WITCH HAZELS.

Although it is usual to speak of Hamamelis virginica as the American witch hazel, and to regard it as the only species indigenous to the New World, there is another distinct kind, which, although sometimes classed as a form of the better-known shrub, is considered to be quite distinct by Transatlantic botanists. H. *virginica* is usually considered as the least decorative of the several witch hazels, and it is certainly a less desirable shrub than the several Asiatic kinds insomuch that it blossoms in autumn, usually before the fall of the leaves, therefore its golden flowers, which have the familiar thread-like petals common to the genus, are less noticeable than those of the various sorts which blossom from leafless branches. It has, however, an asset in autumn which makes it worth planting, for the leaves assume a pretty golden hue before they fall. In its home in Eastern N. America it is regarded as a useful economic shrub, for its bark is used in the preparation of cooling ointments, etc.

The second species is H. vernalis. It is said to form a bush six to seven feet high, with a considerable spread, increase in width being added to by shoots, which appear from underground stems. The leaves are three and a-half to four inches long, and two and a-half or three inches wide, the margins being entire on the lower half and deeply dentate above. They are hairy on the under-surface, and the young bark is also covered with hairs. The flowers have yellow petals, and the inside of the calyx is red. The latter is a distinguishing mark from H. virginica, for in that case the sepals are yellowish-green. The flowering time is also different, for whereas the older plant blooms in autumn, H. vernalis opens its flowers in January. Seen growing side by side at Kew H. vernalis appears to grow later than the other species, for at the end of October the ends of the shoots were not thoroughly ripened, and most of the leaves were green.

D.

TOO-MUCH-ALIKE SWEET PEAS.

The following varieties have been bracketed as too-much-alike by the National Sweet Pea Society, and it is stipulated that "Not more than one of the grouped varieties shall be shown on the same competitive stand at any exhibition of the National Sweet Pea Society." The names are placed in alphabetical order.

Blue—
Anglian Blue
Flora Norton Spencer
Kathleen McGowan
Zephyr

Blush—
Countess of Northbrook
Lady Evelyn Eyre
Mrs. Hardcastle Sykes
Princess Victoria

Carmine—
George Herbert
John Ingman
Mrs. W. King
Paradise Carmine

Cream, Buff, and Ivory—
Clara Curtis
Cream (Dobbie's)
Giant Cream Waved
Mrs. Miller
Paradise Cream
Primrose Paradise
Primrose Spencer
Primrose Waved
Princess Juliana

Lady Knox
Paradise Beauty
Paradise Ivory
Queenie

Cream-Pink—
Earl of Plymouth
Holdfast Belle
Juliet
Mrs. Alec Ware
Mrs. Henry Bell
Mrs. Hugh Dickson
Mrs. Routzahn
Mrs. S. S. Champion
Queen (Sutton's)
Queen Mary
Romani Rauni
Seashell
W. T. Hutchins

Cream-Pink (deep)—
Anglian Pink
Doris Usher
Lancashire
Minnie Furnell
Miriam Beaver
Mrs. Gibbs Box
Mrs. R. Hallam
Syeira Lee

Constance Oliver
Nell Gwynne

Crimson—
Anglian Crimson
Dodwell F. Browne
King Edward Spencer
Maud Holmes
Northumbrian Crimson
Paradise Crimson
Rosie Gilbert
Sunproof Crimson
The King
The Squire

Lavender—
Asta Ohn
Masterpiece
Mrs. Charles Foster
Mrs. E. Noakes

Florence Nightingale
Freda Unwin

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Horticultural Club.

TRAVELS IN BULGARIA.

On Tuesday, December 7, after the usual monthly dinner at the Windsor Hotel, presided over by W. A. Bilney, Esq., and at which a goodly numberof members and guests were present, a very interesting lecture, illustrated by lantern slides, prepared from original photographs and entitled "My Travels in Bulgaria," was given by Mr. Herbert Cowley.

The visit was made before the outbreak of the present war, but the lecturer gave a very vivid idea of the complicated "tangle," as he termed it, involved by the curious mixture in Bulgaria of natives of various and, as a rule, hostile nationalities and religions, which, of course, is not by any means ameliorated by the influence of the Turkish domination which has now presumably been thrown off by the recent outbreak.

Apart, however from the political associations, the country is very interesting from the botanical and horticultural point of view, a range of fairly lofty mountains reaching altitudes of 1,200 feet or more, providing habitats for a very varied flora and material for some very fine photographs of alpine and other plants in situ, which evoked much admiration. More particularly, the fact that Bulgaria is so much the home of the rose, that it is the source of that valuable essence known as "attar of roses," was of interest, and photos of the girls who are mainly the workers of that industry were reproduced in groups, which, however, failed to show such transcendent beauty as should be properly associated with so poetic an employment as the culling of the Queen of Flowers. Inasmuch as about 100,000 blooms had to be gathered to produce an ounce of attar, it is clear that its high value in the market is fully justified. Photos of natives and native priests, and also of their towns and villages, with the accompanying remarks, showed that cleanliness and godliness were not at all associated there, an article in the popular creed being indeed the sinfulness of washing at all, while the 'roads" were clearly rather preadamic than macadamic, being entirely unpaved even in the towns.

Poverty seemed the rule everywhere, the dwellings being of the most ramshackle kind, the inhabitants, both in costume and habits, matched their domiciles to a nicety. A portrait was shown of the King of Bulgaria, who, fortunately for Mr. Cowley, is himself an ardent horticulturist, and, as a result, gave him every facility and a guide, which secured him a hospitable reception everywhere, to his great advantage.

A short discussion followed, and a most cordial vote of thanks concluded a very pleasant and instructive lecture.

Bournemouth Gardeners' Annual Supper.

On Tuesday, January 7, the annual supper took place in the Avenue Assembly Room, Town Hall Avenue. There was a good attendance of members, presided over by Mr. Charles Stewart, F.R.H.S., a vice-president. The president, Mr. J. H. Ralph Smythe, J.P., F.R.H.S. was unavoidably absent.

The officials had very favourable reports to make. There had been a net gain of eleven new members during the past year. Two only had been lost to the society, one through death and the other had gone abroad. The total membership was now nearly one hundred and fifty. The finances of the society were in a very satisfactory state, there being a substantial balance in hand. The meeting was an enjoyable one throughout.

Ulster Horticultural Society.

The annual meeting of this society was held at Ye Olde Castle Restaurant, Castle Place, Belfast, on the 9th inst., with the High Sheriff of Belfast in the chair. There was a good attendance, among those present being: Mr. Alex. Dickson, Mr. R. Watson (the treasurer), Mr. Hugh Dickson, Mr. S. McGredy, J.P., Mr. Thomas Paul (the hon. secretary), and Mr. J. MacBride (the acting secretary).

After the minutes of the previous annual meeting had been read and adopted, the following report of the committee was submitted to the meeting: The twenty-fourth show of the society will probably be remembered as one of the finest, if not the finest, held under the society's auspices. In practically every department a distinct advance in quality and arrangement was noticeable. The spacious market was taxed to its utmost capacity to accommodate the numerous exhibits; never before has the cut flower section been of such extent and of such uniformly high excellence. Although the past season was one of the most adverse to the successful cultivation of fruit, seldom has a brighter or better display been staged in Ireland, the exhibition of pears being far above the average. Vegetables were a distinct and prominent feature of the show. The various collections shown were magnificently staged, and evidenced a high degree of cultural skill on the part of the exhibitors. This was particularly the case in the collection staged by Mr. Gibson, gardener to his Grace the Duke of Portland, Welbeck Abbey, which was probably the finest collection of vegetables ever staged in Ireland. The magnificent exhibits of the florist's art staged by Messrs. Alexander Dickson and Sons, Lim., Messrs. F. E. Smith and Co., and Messrs. A. S. Ritchie and Co., were a prominent feature of the show, and drew from the English and Scottish exhibitors and judges unstinted praise and admiration, and the encouraging assurance that in this department Belfast was far ahead of all other similar displays. The groups of stove and greenhouse plants and chrysanthemums were of a very high standard, and, although not quite so numerous as the previous year, attracted admiring crowds throughout the show. Special mention must be made of the magnificent group of conifers shown by Messrs. Hugh Dickson, Lim., in connection with which were introduced groups of their new roses.

Notwithstanding the fact that the society's shows are amongst the most beautiful and educative in the United Kingdom, it was with regret that the committee had to record a falling-off in public interest, the gate receipts having fallen about £37, and that under very favourable weather conditions. That, unfortunately, had been the experience of almost every large horticultural society in the country, as a perusal of their annual reports conclusively proved. Many explanations were attempted, the most general being the number and popularity of picture houses, which have sprung up in such large numbers everywhere within the last two years. Whether this be the real reason or not, the committee feel that they are faced with the fact that further support from the general public is necessary if the society is to continue its steady course of progress, and if its annual shows are to be in the future, as they have been since the inception of the society twenty-four years ago, a yearly record of the progress of horticulture in Ireland and an object-lesson of the possibilities of skilful cultivation and scientific methods.

Through the generosity of the Department of Agriculture and Technical Instruction for Ireland, the committee was enabled to extend the apple orchard competitions by inaugurating a new competition for young orchards from three to ten years old. A competition of this nature was much required, and they anticipated it would become a great stimulus to those planting orchards.

Mr. Robert Watson presented the financial statement, from which it was seen that the year was commenced with a credit balance of £83 5s. 1d. The total receipts were £802 19s. 5d., and the balance in bank at the close of the year was £66 15s. 11d.

The Chairman, in moving the adoption of the report and financial statement, said the falling-off in the receipts was not so bad as it seemed on the surface, as it only reduced their credit balance by a sum of about £17. The public had not during the year supported the society as they ought to have done. The annual exhibition was immensely attractive, and it was surprising that a greater number of those resident in and around Belfast did not embrace the opportunity of seeing the progress which is being made in horticulture, as indicated by the specimens of flowers, fruit, and vegetables which were sent in for competition. He was glad to learn from the report that their last show was the best which had been held under the auspices of the society, so far as quality was concerned, although the attendance should have been more satisfactory. He hoped that in the present year they would try to obtain more subscribers, so that at the next annual meeting they might be able to report an increase in their receipts.

Mr. Alexander Dickson, who seconded the report, said, as one of the active workers on the committee of the society, he wished to thank the chairman for the encouraging remarks he had made respecting the progress of the society and its educational value in horticultural matters in the North of Ireland. It was very gratifying to the members of the committee to know that their efforts were being appreciated, not only in the city of Belfast, but throughout the whole province of Ulster. They received congratulatory messages from all over Ireland; and it was generally acknowledged that of all the horticultural societies which had come into existence in the last quarter of a century none had enjoyed such long and eminent success in the face of such great difficulties as had the Ulster Horticultural Society.

The election of office-bearers was, on the motion of Mr. A. J. Morrow, as follows: President, the Lord Mayor of Belfast (Mr. R. J. M'Mordie, M.A., M.P.); committee, Messrs. John R. Allen, Thomas H. Dickson, Wm. M'Laren, F. W. Moneypenny, Wm. T. Braithwaite, R. Meyer, Alex. Dickson, R. Jamison, W. J. M'Clements, R. Draper, John Atkinson, A. Graham, D. Baillie, F. J. Dolan, R. Ewing, Robert Wilson, Thomas Bradshaw, John Harding, Alex. Dickson, J. B. Sproull, Hugh Dickson, Robert Irvine, W. H. Andrews, J.P., F. E. Smith, John Whytock, S. M'Gredy, J.P., James Davies, James M'Cormick, P. J. Tiernan, J.P., S. Graham, A. J. Morrow, Isaac Smith, Thomas M'Ervel, H. P. Pinkerton, F. J. Leitch, Wm. Watson, and A. S. Ritchie; hon. treasurer, Mr. Robert Watson; hon. secretary, Mr. Thomas Paul; secretary, Mr. J. MacBride.

A hearty vote of thanks to the High Sheriff brought the meeting to a close.

Royal Caledonian Horticultural Society.

The annual general meeting of the Royal Caledonian Horticultural Society was held in Dowell's Rooms, George Street, Edinburgh, on January 8. Mr. D. W. Thomson, senior vice-president, was in the chair, and there was an attendance of about 30.

The report for 1912 stated that, notwithstanding the bad season, both the spring and autumn shows had been well maintained as regards entries, the latter being the best autumn display since the International Show of 1905. The abstract of the accounts showed a small balance of income over expenditure, and it was mentioned that it was gratifying to observe that the public was giving the shows more patronage, the drawings for the two shows representing an increase of £45 on the previous year. The report was adopted, on the motion of Mr. J. W. McHattie.

Mr. J. Stewart Clark, of Dundas, was re-elected president, and Mr. J. D. Adair was elected vice-president. Messrs. Kidd (Carberry Tower), Methuen (Edinburgh), and Plant (Edinburgh) were elected to fill the vacancies on the Council.

Dundee Horticultural Association.

The ordinary monthly meeting was held in the Technical College on the 10th inst. The President, Mr. William Christison, occupied the chair, and there was a good attendance of members and friends interested in the subject, which was "Notes on the Great International Horticultural Exhibition, Chelsea, 1912." Mr. James Beats, Binrock Gardens, was the lecturer, and dealt with the subject in a racy and interesting manner, and with the aid of lantern slides his remarks on the varied features were greatly enhanced. Although upwards of five dozen slides were shown on the screen, each depicting an interesting feature, Mr. Beats remarked that justice had not been done to it, as the magnitude was bewildering. The rock and water gardens and the orchid tent and some of the outstanding trade exhibits formed the chief topics of his notes, which were heartily appreciated by those present.

Dumfries and Galloway Gardeners' Association.

The first ordinary meeting of this newly-constituted association was held in St. George's Hall, Dumfries, on the evening of January 11, when there was a good attendance, considering the inclement weather, the heavy snowfall, the worst for eighteen years, preventing many of the members from a distance from being present. Mr. S. Arnott occupied the chair during the first part of the meeting, when the byelaws submitted by the committee were approved of. Mr. Croall was then called to the chair, and Mr. S. Arnott delivered his lecture on "Alpine and Rock Plants," which was illustrated by between fifty and sixty lantern slides of many of the most useful alpine flowers. The lecturer briefly discussed the leading points in the cultivation of the plants, and gave much useful information respecting the plants shown on the screen. An interesting discussion, taken part in by Mr. Croall, Mr. Sturrock, Mr. Reid, Mr. Hunter, and others followed, and Mr. Arnott was heartily thanked.

Woolton Gardeners' Society.

This society held its twenty-fourth annual meeting on the 9th inst. at the Mechanics' Institute, when Mr. Jos. Stoney occupied the chair.

The report gave evidence of a good season's work, the attendance being satisfactory throughout. The committee recorded a great difficulty in securing capable lecturers in the immediate neighbourhood, but they have been successful in securing some excellent practical essays by men specially able in their respective subjects. The under-gardeners showed an increased interest in essay-writing five competing for the prizes for a paper on "Sweet Pea Culture," an improvement on the past few years, which was followed by a satisfactory report from the adjudicator. The excellent library and microscope owned by the society have again proved useful. The balance-sheet showed an increased balance in hand of one pound on that of last year, the amount standing to the credit of the society at the present time being £7 0s. 9d. Mr. R. G. Waterman was re-elected as hon. treasurer and secretary.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

ANSWERS TO CORRESPONDENTS.

SAXIFRAGA APICULATA. — F. S. L., Warwick: I have never been very successful with the popular and beautiful Saxifraga apiculata. I grow it in a sheltered position on my rockery, and it receives a fair amount of sunshine. The soil is a trifle heavy, but otherwise there seems no good reason why I do not understand how it is the plants never attain a good size and spread as they do in so many gardens?—Saxifraga apiculata is one of the easiest of species to cultivate, and there must be something very much at fault if it is a failure. A position fully exposed to the sun should be provided, and this must be well drained. Give it such a position, and plant it in a compost consisting largely of grit and limestone, and it should succeed. A limestone soil suits it particularly well.

CANOE BIRCH.—F. F., Galway: Will you please tell me what species of birch is used in North America for the purposes of canoe making?—Betula papyracea is the species formerly used extensively for making canoes in North America. It has very flexible branches, and the bark peels well and in large pieces if properly handled. The bark of B. papyracea has also some value for paper-making, and this has suggested the specific title. It may be added that a large number of species of birch are natives of Canada and the United States, and, doubtless more than one species has been used for the manufacture of canoes. The birch trees are very hardy; indeed, our common or Silver Birch is the tree that grows "farthest north," though in Greenland it is very stunted.

HERBACEOUS PLANTS FOR EXHIBITION PURPOSES.—E. W. P., Cambridge: Will you be good enough to give me the names of about a dozen herbaceous plants suitable for exhibition purposes during July and August, and likely to be of real service in a keen competition?—We assume that the flowers, and not the plants, have to be exhibited. We need hardly point out that a good selection of kinds is most desirable, but at the same time high cultivation and careful arrangement of the flowers at the exhibition are of the first importance. Where the class is for a dozen bunches, then many more than a dozen kinds must be grown, because the influence of the season, soil, and position must be taken into account, and some considerable latitude allowed for contingencies. Some kinds that should be grown are Oriental poppies, delphiniums, Lilium candidum, L. umbellatum, L. auratum, L. speciosum, L. Lychnis chalcedonica, some of the coloured astilbes of the A. Arendsi group, such as Ceres, Salmon Queen, Venus, Vesta, or Gerbe d'Argent; Japanese and other irises; gaillardias, Lychnis chalcedonica, Galega Hartlandi, Erigeron speciosum; some of the finer forms of Chrysanthemum maximum, such as Mrs. Lothian Bell, Wm. Robinson, King Edward, etc.; Sidalcea candida, gladioli, Campanula Moerheimi, C. lactiflora, C. latifolia macrantha, Stenanthemum robustum, Galtonia candicans, Helenium pumilum, Scabiosa caucasica, some of the finer phloxes, such as Frau von Buchner, Coquilicot, Belvedere, Iris, and Selma; Anchusa italica Dropmore var., herbaceous lupins, Platycodon grandiflorum, pyrethrums—especially the bright single varieties like Jas. Kelway; Monarda didyma Cambridge var.; Lobelia cardinalis and L. Queen Victoria; Lathyrus latifolius The Pearl; Kniphofia caulescens, K. Pfitzeri, K. Lemon Queen, K. Tucki, etc.; heucheras, Geum Mrs. Bradshaw, Eryngium alpinum Asclepias tuberosa, hollyhocks, and Achillea ptarmica fl.-pl. The Pearl. Selections must be made according to the space that can be devoted to herbaceous plants, and no selection of twelve kinds would suffice for competitions during both July and August. All the foregoing are excellent border plants, and of every kind and variety mentioned we have seen fine bunches in prize-winning sets during the past season. In arranging the flowers on the exhibition stage, due consideration must be given to colour effect, and crowding innumerable spikes or blooms into each vase should be avoided. It is far better to have fewer flowers or spikes, and these of first-rate quality, than a host of third-rate ones.

LARGE ONIONS.—H. G., Bedford: I wish to obtain a good crop of fairly large onions, not necessarily for exhibition purposes, but because I am very fond of good-sized specimens cooked whole. If you would kindly give me an outline of the methods necessary to secure strong plants for early planting I shall be obliged. So far, I have depended entirely upon outdoor sowings in spring and autumn. I may say that onions do very well here.—We hope to deal with this matter more fully in an early issue, but for the present we advise you to sow your onion seeds thinly in boxes of fairly light soil, place the boxes in a warm greenhouse, where the temperature is from 55 to 65 degrees. Give one good watering after sowing, and then very little more will be needed for some time. When the seedlings are large enough to handle they should be pricked out into other boxes. The latter may be about 2ft. long, a foot wide, and five inches deep, and prepared by placing a layer of old rotten manure in the bottom, and filling with fairly rich soil. Make the compost firm, and prick out the seedlings three inches apart each way. Keep the boxes well up to the glass in the warm house, but as soon as the seedlings have re-established themselves a gradual process of hardening off must commence, and presently a cold frame will afford sufficient shelter, and subsequently the lights must be removed so that the onions are quite hardy and robust, and ready for planting towards the end of April.

NAMES AND SYNONYMS OF ROSES.—B. J. K., Chippenham: As rose-growing is now such a widespread hobby, and as raisers crowd new varieties of the Queen of Flowers upon us each year, there seems to be a great need for a complete list of names of roses, and, more particularly, a need of a list of synonymous varieties. There are, I know, several extensive lists of rose names, but none of these seem to be anything like complete, but, perhaps, there may be one known to you. If that is so, will you kindly tell me where I can obtain it?—By far the most complete list of names of roses we know is published by the Librairie Horticole, 84bis Rue de Grenelle, Paris. Its title is "Nomenclature de tous les Noms de Roses"; it was issued in 1906 and compiled by MM. Leon Simon and P. Cochet. Of large octavo size, it extends to 178 pages, and contains name, group or family, raiser, date of introduction (in most cases), and colour of eleven thousand and sixteen varieties of roses; many synonyms are noted, probably fewer than a thousand. This would leave ten thousand names plus the many varieties named since 1906.

IS LEPTOSPERMUM SCOPARIUM HARDY? — O. C., Grantham: I ask the question, Is Leptospermum scoparium hardy? chiefly because I wish to draw attention to a very pretty and rarely-grown flowering shrub from New Zealand, but also because it would prove very instructive and interesting if readers of the GARDENERS' MAGAZINE would write and state the gardens and counties wherein the species is grown out of

Spraying

The question to-day is not **"Shall we Spray,"** as every gardener knows he **must** Spray, but "What machine or syringe shall I spray with?" All the world answers, Use **only** the **reliable** tested

"FOUR OAKS"

Burpee's Annual for 1913

"The Leading American Seed Catalog"

Is now ready for mailing. The first edition of more than four hundred thousand copies will soon be distributed. As usual it is sent unsolicited only to "Customers of Record." We shall be pleased, however, to mail a copy immediately upon application (a postal card will do) to every one who appreciates QUALITY IN SEEDS.

This SILENT SALESMAN (and we employ no "talking" salesmen to solicit orders) tells the plain truth about The Best Seeds That Can Be Grown. Besides coloured plates of Burpee-Specialities, this bright book of 180 pages shows hundreds of the choicest vegetables and most beautiful flowers, illustrated from photographs. It is almost indispensable to all who garden either for pleasure or profit.

The "HOUSE OF BURPEE" is known the world over not only as EXPERTS IN SWEET PEAS but also as SEED SPECIALISTS. No other American firm has ever introduced so many novelties of sterling value—and no other growers supply seeds annually direct to so many planters. It might be to your interest to read THE BURPEE-ANNUAL. It will cost you only one cent for a post-card to send us your address, and you are under no obligation to buy. We never annoy applicants with "follow-up" letters!

Shall we mail **you** a copy? If so, kindly **write to-day.**

doors without any other protection than is afforded by walls, terraces, or mansion. I am led to ask the question in this general fashion because the plant is referred to by two writers in the very entertaining issue of the "G. M." for January 4 this year. "W. T.," in reviewing "New Hardy Trees and Shrubs of 1912," gives first place to Leptospermum scoparium Nicholi (the crimson-flowered variety that gained a Silver Cup and a F.C.C. at the International Horticultural Exhibition of 1912), and says that "leptospermums are tender in most parts of these islands." I wonder whether "most parts" is correct? In his description of "Nuneham Park and Gardens," Mr. C. H. Curtis tells us that outside the terraces "a long border is largely filled with the pretty Leptospermum scoparium, an Antipodean Myrtaceous shrub which flourishes here so well that self-sown seedlings are quite numerous." Further, I believe that L. scoparium has withstood a dozen or so degrees of frost in the gardens at Belvoir Castle. My point is that if L. scoparium is hardy at Grantham, it ought to be hardy (with a few easterly exceptions) everywhere south of a line drawn across England, Wales, and Ireland, a little below the 53rd degree of latitude, and I fancy "most parts of these islands" would come south of this line.—"O. C." raises a very interesting matter, and we should be very glad if any of our readers living north of, say, Leicester, or in what are regarded as cold districts farther south, would tell us whether Leptospermum scoparium is hardy in their locality. The introduction of L. s. Nicholi has stimulated interest in this group of shrubs, and the plants are so beautiful when full of bloom that a wider knowledge of the range of their hardiness would prove most useful, especially when the newer varieties come into commerce.

NAMES OF PLANTS.

D. D., Nantwich.—Jasminum nudiflorum.

NEWS FROM HEADQUARTERS.

PEDIGREE.

Stockbreeders have constantly before them the question of pedigree; and whether it be horses, cattle, sheep, pigs, or pigeons in which they are interested, the same conditions apply.

However perfect an animal may be, it is not considered suitable for perpetuating its species unless its parents for generations have an unblemished record.

It is, almost without exception, only those animals which have been carefully bred through numerous generations that are able to prove their superiority over others.

In the case of Horticultural subjects the same extreme care and attention to the most minute details of breeding are essential, and the analogy between the animal and vegetable with regard to pedigree breeding are very much closer than is generally recognised. Stocks of choice garden peas require the same principles of pedigree breeding as Race Horses and Homing Pigeons.

It is difficult to write of the many interesting phases of breeding and selecting Pedigree tested Seeds, but a visit at this season to the commodious premises of Messrs. Carter, at Raynes Park, will quickly convince one of the necessity and importance of the scientific and practical methods upon which the world-wide reputation of Carter's Tested Seeds has been built up. A visit also in the Summer months will prove of great interest when the trials are in full growth.

JAMES CARTER & CO.,

Seedsmen to His Majesty the King.

RAYNES PARK, LONDON, S.W.

VOL. LVI.—No. 3,091. SATURDAY, JANUARY 25, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Greater Snapdragon.

The procession of Time, as it proceeds ever onward in the path of progress, brings in its train many changes that affect in varying degrees all classes of the community, and produces a profound influence upon those who take an active interest in what is constantly going on around them. Probably no members of the body politic are more forcibly reminded of the changeability of methods of procedure and matters of taste than those who are concerned with the garden and its occupants. They share in the effects of the changes that concern all, whatever may be their avocations or tastes; and, in addition, they have constantly before them the reminders that the various classes of plants in which they are greatly interested are so well able to afford. They will not have long been engaged in gardening, whether as a hobby or a means of livelihood, before they discover that there are fashions in flowers as in other matters, and that kinds which have enjoyed a high degree of popularity for one or more decades are pushed on one side by others of more recent introduction that have caught the public fancy, and have thus been fortunate in obtaining general recognition of their merits. These changes are, it may be assumed, very trying to those who have devoted a considerable part of their activities to the cultivation and probably the development of certain classes of plants, to watch them slowly but surely declining in public favour, and finally see them superseded by other subjects. Those who pass through such an ordeal have our fullest sympathy, however warmly we may welcome the newcomers. Such changes have constantly to be borne, and happy are those who can bear them in a philosophic spirit, and recognise the fact that, were it not for the influence of fashion, and the desire of those engaged in plant improvement to create new forms, the garden would, in comparison with existing conditions, be lacking in interest, and possess fewer charms. It should also be borne in mind that these frequent changes indicate continuous progress in those sections of the plant world that receive the attention of those more or less concerned with the art of gardening. The varieties of the Greater Snapdragon which have leapt into public favour within the past few years, as a consequence of the immense improvements that have been effected in them, afford a remarkable proof of this. Early in the last century the varieties then available enjoyed a considerable degree of popularity; but at this time several plant collectors who had been sent out in quest of plants from other regions were actively engaged in their work, and were so successful as to considerably enrich our garden flora. As the new plants became distributed, some of the old favourites had to be banished or relegated to the background in exactly the same manner as at the present time. We find evidence of this in a book of repute that was published in the first half of the last century. The author writes: "The antirrhinum may be considered rather a rustic than an elegant plant, and it should therefore not occupy a place amongst choice flowers, but should be mixed with the shrubs in the background, or placed on the banks or most elevated parts of the grounds, where in large clumps it produces a showy effect from the end of spring to the autumn." There may be some difficulty in realising that such beautiful flowers as the antirrhinums unquestionably now are, could with any degree of propriety be relegated at even an early stage of their development to the shrubbery border, or to that part of the grounds now known as the wild garden, because of their unfitness for association with choice flowers. Such was, however, the case, and the advice given by the old author is fully justified by the illustrations of the antirrhinums as seen in gardens at that time. The difference was immense between the present-day race and varieties that were available seventy or eighty years ago. The growth was evidently tall and straggling, the flowers comparatively small and rather thinly arranged on the spike, and the colours were few in number, and the best of them were much less attractive than any of the shades that are now obtainable. Both in habit of growth and flower development they were not much better than the antirrhinums which may be seen on the rocks at Dover, and on old walls and banks in some other parts of the country, where in the distant past they became established on their escape from neighbouring gardens. The Greater Snapdragon is sometimes described as a member of our native flora, but it is an alien, albeit a beautiful one, and its home is in the South of Europe. Several of its varieties have long been in our gardens, and John Parkinson enumerates in his "Paradisus" (1640) white, yellow, blush and yellow, and rose-coloured forms; and in such manner as to suggest that they were of specific rank. With reference to them he writes, "All these are nourished by us in our gardens, although in Spain and Italy they are found growing wild." For how long a period the Greater Snapdragon has had a place in our gardens it would not be easy to determine, for there is no information available relating to the year of its introduction. It would be hardly less difficulty to state with the proper degree of exactness the period over which the work of improvement on systematic lines extended. The development of the antirrhinum as we now know it is a quite modern achievement. From the time Phillips described it as unsuitable for associating with choice flowers, until the hardy flowers were practically swept away from many gardens to make way for the brilliantly-coloured masses of tender plants, nothing was done to improve the habit of growth or develop new colours. Moreover, for long after

MR. G. MULLINS.

scarlet pelargoniums, yellow calceolarias, and blue lobelias had made their triumphal entry into the flower garden, the antirrhinums had to take refuge in cottage and other gardens in which the facilities did not exist for annually raising large numbers of tender bedders. It is now some years since we had the opportunity of becoming acquainted with the efforts that were being made in several directions to obtain by selective culture varieties with a free, branching habit, flower spikes on which the blooms are closely arranged, and yielding a great diversity of colouring than was previously available. In the earlier stages the progress was rather slow, and did not, perhaps, obtain the attention it so well merited; but of late years the pace was quickened, and, when the results of the work of the several raisers were combined, flower lovers at once saw that they had at their disposal a race of plants of immense value for beautifying their gardens, and were not slow to take advantage of their opportunities. We have on several occasions during the past decade directed attention to what was being done, and advised our readers to take full advantage of the newer types; and it gives us much satisfaction to know that our efforts have contributed appreciably to the popularity which the antirrhinums now enjoy. The raisers have, with remarkable judgment, taken into account the different position the various classes of plants have to occupy, and the diversity of taste that exists, and shaped their course accordingly. They have, in the progress of their work, developed three groups, differing chiefly in height. There are the tall varieties, with an average height of three feet; the intermediate varieties, with a height of eighteen inches; and the dwarfs, with a height of six or eight inches. The development of new colours is, perhaps, even more remarkable, for in each group there are varieties with blush, carmine, coral-red, chamois, cinnabar-red, crimson, pink, lemon-yellow, golden-yellow, striped, white, and rose-coloured flowers. All the varieties have a more or less free branching habit, and bloom freely and continuously from quite early in the summer until the autumn, and throughout the whole period produce effects of surpassing beauty. The continuity of flowering depends upon the plants being strong when bedded out, the soil being sufficiently rich to maintain a free growth, and the removal of the flower spikes as soon as the beauty of the flowers is passed, that the energies of the plants may not be taxed by seed production. The plants may be raised from seeds in an unheated pit in August, and the seedlings be wintered in a similar structure: or the sowing may be made in heat in February or March, and the seedlings grown on steadily with a little warmth, and in due course thoroughly hardened off. Antirrhinums are hardy, and when located on an old wall, or growing in a light sandy soil, will pass through a winter of average severity without injury, but the best results are obtained by raising a fresh stock of plants annually, in accordance with the foregoing suggestions.

Mr. G. Mullins has occupied the position of head gardener to Lady Henry Somerset during the past seventeen years, and throughout the period he has had charge of the Eastnor Castle Gardens he has brought to bear on their management cultural skill and administrative ability of so high an order as to greatly enhance the reputation they have so long enjoyed, and to obtain for himself a foremost place among the leading horticulturists of the country. There has not been a time within the recollections of those actively engaged in gardening when the gardens of Eastnor Castle have not been famous for the fruit grown within their boundaries, and it is a point of some interest that at no period was the fame higher than at the present time, while other departments have been maintained in a manner worthy of their traditions. Throughout the whole of the period Mr. Mullins has been at Eastnor Castle he has exhibited, without a break, in the classes for large collections of fruit at Shrewsbury. Last year he was successful in winning the silver cup offered as the premier award in the class for a collection of choice fruit at the Royal Horticultural Society's fruit show, and he was not less successful at the Birmingham Chrysanthemum and Fruit Show. Entering the eight classes for fruit collections, he was awarded five firsts and three seconds—a success that of itself is sufficient to indicate Mr. Mullins' ability both as a cultivator and exhibitor of fruit. Of special interest in the gardens of Eastnor Castle is the old Black Hamburgh vine, which is upwards of one hundred years old and fully occupies a span-roof house 80ft. long by 18ft. wide. The cultivation of hardy fruits in the open is not less important than the growth of choice fruits under glass, and of special interest are the trees that clothe the twelve hundred yards' run of walls which range from six to twelve feet in height. Mr. Mullins regards with much favour the cordon system of training, and those who have an opportunity of seeing the trees have no difficulty in understanding his high appreciation of the method. Even peach trees are grown as cordons, and Mr. Mullins finds that he obtains much better results from them than from fan-trained trees. Perpetual-flowering and Malmaison carnations are grown very largely, and with so much success as to constitute an important and highly attractive feature. Mr. Mullins is by no means a specialist, for while we find him obtaining high distinction as an exhibitor of fruit, we have unquestionable proofs of his skill in the pleasure grounds, which have an area of about eighty acres, and are remarkable for the magnificent specimens of coniferous trees.

Proposed Testimonial to the Rev. W. Wilks.—With the annual meeting on February 11 the Rev. W. Wilks will complete the twenty-fifth year of his secretaryship of the Royal Horticultural Society, and a strong desire is being felt by those who are fully acquainted with the splendid services he has rendered to horticulture in general, and the society in particular, to mark the occasion by presenting him with a suitable testimonial. A circular, signed by Sir Trevor Lawrence and a large number of Fellows, is on the point of being issued, and in this it is stated that, "On the 11th prox. the Rev. W. Wilks, M.A., V.M.H., will have served twenty-five years as secretary of the Royal Horticultural Society; and it is thought by many of those closely associated with him in the society that the occasion should not be allowed to pass without some recognition of the event, and of the valuable work he has done during this long period. The hold the Royal Horticultural Society has established on public confidence has led to a success which may almost be described as phenomenal. This has been, in part at least, due to the labours of Mr. Wilks, and the Council have always felt that they might rely upon his tact, judgment, and resource to help it to meet the difficulties it has had to contend with from time to time. The result has been that a large body of Fellows feel anxious to take advantage of this opportunity to mark by a suitable recognition their appreciation of the valuable services rendered to the society by Mr. Wilks during a quarter of a century. This should take, they propose, the shape of a testimonial, subscriptions to which are not to exceed one guinea. As it is hoped to make the presentation at the society's annual meeting (February 11), will you kindly, if you are willing to support the proposal, send your subscription to the Manager, London County and Westminster Bank, Victoria Branch, Victoria Street, Westminster, S.W. Cheques and postal orders should be crossed 'Wilks Testimonial.' Mr. W. A. Bilney, a member of the Council, has kindly undertaken the duties of hon. secretary, and all communications (except subscriptions) should be addressed to him at Temple Chambers, Temple Avenue, London, E.C."

Veitch Memorial Trust.—At a meeting held on Tuesday last by the trustees of the Veitch Memorial, the sum of £100 was contributed to the fund which is being raised for the purpose of publishing a new edition of Pritzel's "Botanical Index." The trustees also awarded a Veitch Memorial medal to Mr. W. H. Adnit and Mr. W. Naunton in recognition of the splendid services they rendered in the development of horticultural exhibitions in Shropshire. They also presented a silver Veitch Memorial medal to the National Dahlia Society to be awarded for the best display of garden dahlias exhibited by amateurs at the society's exhibition of garden dahlias at the Royal Horticultural Hall in September next.

The National Chrysanthemum Society will hold its annual meeting at Carr's Restaurant, Strand, W.C., on Monday, February 3, at 7 p.m., when the President, Sir Albert K. Rollit, is expected to preside. The Society's Floral Committee holds its annual dinner and social evening at Carr's Restaurant on Monday, February 17, when Mr. D. B. Crane will preside.

Shrewsbury Floral Fete.—We understand that Mr. George Brazier has been appointed by the Shropshire Horticultural Society as secretary, in succession to Messrs. Adnitt and Naunton, to whom he has acted as assistant for many years.

Horticultural Club.—The annual general meeting of this club will be held in the Club Room at the Hotel Windsor on Tuesday, February 4, at 5.30 p.m., with the president, Sir Frank Crisp, Bart., in the chair. The annual dinner will take place on the same date at the Hotel Windsor, at 6.30 p.m. The proceedings will be interspersed with a musical programme provided by the President.

Provision of Open Spaces in Surrey.—The refusal of the Surrey County Council to contribute to the fund for the extension of Wandsworth Common and to other projects of a similar nature has given rise to considerable dissatisfaction in the county. In consequence thereof, a sub-committee was appointed by the General Purposes Committee to consider the whole question, and report as to the principles that should guide the Council in making contributions under the Open Spaces Act of 1906. The recommendations of the sub-committee were presented to the Council at its last meeting, and unanimously adopted. These were to the effect that before the Council undertake to contribute either to the capital cost or to the maintenance of an open space it must be proved—(1) that an open space is urgently required in the district; and (2) that the minor local authorities concerned are prepared to make an adequate contribution towards its capital cost and maintenance. While each proposal will necessarily have to be considered on its merits, the County Council should not contribute more than (1) one-sixth of

the capital cost in the case of an open space of local advantage only; and (2) one-fourth of the capital cost in the case of an open space of widely-enjoyed advantage.

Onion Culture on Small Holdings.—In the course of a lecture on "Small Holdings" given before the North of England Horticultural Society, Mr. W. B. Little, the senior horticultural instructor, referred to the suitability of the onion crop for such holdings. He said that, in his opinion, the growing of onions on a larger scale might with advantage be encouraged in certain districts. He did not attempt to supply any data regarding the income to be derived from this crop, but he pointed to the traffic between places like Brittany, and England in this commodity. Thousands of tons, he said, are shipped to England each year, and those responsible go about selling them from door to door, and while doing this they have to spend money on food and clothing, but nevertheless, he was told that many of these men take enormous sums of money back with them. To him it seemed feasible that this crop could be grown at home with equally profitable results. If not, there must, he thought, be something wrong somewhere.

The Free Distribution of Seeds in America has assumed such large proportions as to have become a serious business. The preparation of the seeds for distribution through the post last month was commenced early in November by the Department of Agriculture, and upwards of 600 tons of seed have been put into, approximately, 60,000,000 packets. Arrangements were this season made under the direction of the Bureau of Plant Industry for a special distribution of seeds of plants adapted to dry land conditions. The object is to afford cultivators in the great plains and other dry sections an opportunity for becoming acquainted with the crops that are best suited to dry soils.

A Novel Christmas Gift.—Mr. W. Atlee Burpee, on behalf of Messrs. W. Atlee Burpee and Co., Philadelphia, U.S.A., presented their employees with a novel Christmas gift recently. To every male employee was given a box of cigars, and a present of money, and to every woman a box of candy and a present of money, while, in addition, every employee received a life insurance policy for an amount equal to the recipient's salary for a year, the sums ranging from 500 to 5,000 dollars. Needless to say, these gifts were greatly appreciated.

Precocity of Spring Flowers.—Within the past fortnight a considerable number of letters relating to the precocity of spring flowers this season have appeared in the newspapers. As evidence of the influence of the mild weather that we have experienced on the flowering of plants that usually bloom in spring they have been of little value. The writers of the majority of the letters were evidently unable to differentiate between the plants that naturally bloom during December and January and those which, in normal seasons, produce their flowers in spring. For instance, Garrya elliptica, Eranthis hyemalis, Chimonanthus fragrans, Jasminum nudiflorum, witch hazels, and certain heaths, all of which belong to the winter, were included in the majority of the list of spring flowers that were flowering in advance of their proper season. A notable exception is the list which Miss Armitage, of Dadnor, Herefordshire, has contributed to "Nature." In this the ordinary and abnormal times of flowering are given, and the list is, therefore, of considerable value for purposes of reference. Miss Armitage writes: "The winter aconite began on December 8, and has been flowering profusely since the middle of the month, when about a hundred blossoms were gathered in one day; other early dates are December 20, 1911; December 23, 1897; the first week in January is the mean, the latest January 27, 1887. Green hellebore, January 10; usually end of February; latest, March 26, 1902. Fœtid hellebore, December 1; usually early February, latest February 21, 1904. Lesser celandine, December 1; usually early February; latest, March 12, 1900; other early records, January 20, 1898 and 1901. Wild white sweet violet in the hedges, January 5, many to be seen now, whereas mid-February to early March is its usual season. Pyrus japonica on many walls has been as much covered with flowers throughout December as it is usually in April and May. Lonicera fragrantissima, from December 18 onwards; usually begins early in January; earliest, February 10, 1900. Adoxa moschatellina (Moschatel), in bud January 11; usually flowers in April. Petasites fragrans (winter heliotrope), mid-November, occasionally as early, but more usually December and January. Yellow coltsfoot, January 7; usually early March; earliest previously, January 21, 1898. February 20 1897; latest, March 26, 1909. Primroses abundant in December and early January. Omphalodes verna abundant December; usually early March; latest, April 1, 1902. Spurge laurel, December 20; usually early in February; January 12, 1912, January 28, 1898, March 18, 1897. Chimonanthus fragrans, very abundant from November 14; earliest before, December 9, 1907. Yellow crocus, January 5; earliest, January 22, 1901, January 24, 1898. Galanthus Elwesii, November 14. Common snowdrop, December 28; earliest, January 8, 1912."

CŒLOGYNE CRISTATA.

Flowers white, with yellow markings on the lip. A.M., R.H.S., January 21. Messrs. J. Cypher and Sons, Cheltenham.

A HOTBED.

"The stable yields a stercoraceous heap,
Impregnated with quick-fermenting salts,
And potent to resist the freezing blast.

. . . . . .

Warily, therefore, and with prudent heed,
He seeks a favoured spot; that where he builds
The agglomerated pile, his frame may front
The sun's meridian disk; and at the back
Enjoy close shelter—wall, or reeds, or hedge
Impervious to the wind. First he bids spread
Dry fern or littered hay, that may imbibe
The ascending damps; then leisurely impose,
And lightly shaking it with agile hand
From the full fork, the saturated straw."
—COWPER, "The Task," Book III.

For those who have no glass, or only a cool house, a hotbed is almost a necessity in the spring, not only for raising tender plants and striking cuttings, but for raising hardy plants early. The most useful period is from the middle of February to the end of April, after which the advancing season, and the slight warmth from the slowly-fermenting manure, will probably be sufficient to keep the night, or, rather, early morning, temperature from falling below 45 degrees, or thereabouts, if the sashes are covered in the evening. The latter is very important, the covering not only lessening the radiation of heat, but preventing little currents of cold air entering between the overlapping panes of glass, especially in windy weather. Anyone sceptical upon this point should observe the difference in two similar frames, one of which has been covered during the night and the other not, by putting a thermometer in each in the morning.

If it is intended to have a hotbed in working order by the middle of February a quantity of stable manure proportionate to the size of the frame should be collected by the end of January. For a small frame about four feet by three one good load is sufficient, but if the frame is, say, six feet by four, two loads should be used. After the manure is procured, supposing it to have been well turned over in loading and unloading, it should be left for a week—otherwise turned after four or five days and left another few days—after which the bed may be made up, thoroughly shaking out the manure in the process to aerate it and rid it of some of the noxious gases. A quantity of leaves, equal to a quarter or a half of the volume of the manure, may be mixed with it to eke it out, moderate its heat, and sweeten the gases given off, besides lengthening the fermentation process. A layer of leaves should be put over the top of the dung-bed before any earth is put over it. If it is intended to make a bed of earth on the manure, and plants or seeds put in it, the materials should be left another week before making up the bed, and again turned over, or it may heat too violently and kill the young roots; but if the frame is to be used to start with simply for pans and boxes of seeds to be set in it, this risk is much less, even if existent, and the shorter time will suffice.

The site for the bed should be staked out, leaving a foot or eighteen inches more in both breadth and length than the size of the frame. The building up of the bed needs some care, and the novice will probably find one part of the bed sink more than another after a week or two, leaving his frame rather lopsided. Firm and compact building is the secret in putting it together, paying special attention to the corners. When completed the bed should be about three feet high at the top, or back, of the frame, and from two to two and a-half feet at the other end, so arranged that the slope is towards some point of the compass between south-east and south-west, preferably south. If it is to be used for raising seeds, etc., an inch or so of soil should be laid all over it to give it a little surface, sweeten the air of the frame, and absorb some of the ammonia which will rise from the manure.

After the bed is made, and the frame set upon it, some recommend leaving the sashes off for three or four days to let the rank steam escape, but this is not always advisable, as a heavy rain in the meantime may wash much of the valuable fermenting matter out of the dung, and permanently cool it. The sash should be raised at the back for a few days, though pans of slowly-germinating seeds which it is desired to hurry on may be put in at once, the pans standing on the earth being safe from any scorching, and the air becoming sweet before the seedlings appear. To quote our rural poet again:

"Thrice must the voluble and restless earth
Spin round upon her axle ere the warmth,
Slow gathering in the midst, through the square moss
Diffused, attain the surface; when, behold!
A pestilent and most corrosive steam,
Like gross fog Boeotian, rising fast,
And fast condensed upon the dewy sash,
Asks egress."

When the sash is first shut down a thermometer should be put in to see that the temperature does not rise much above 70 degrees, and when this is the case, and the interior smells fairly sweet, plants, cuttings, bulbs, and anything which it is desired to expedite may be put in, especially any early-flowering chrysanthemum stools which are slow in sending up shoots for cuttings. Plenty of air must be given or mildew will soon appear, but the end of the sash that is raised should be away from the cold winds. If it is shut down in the middle of the afternoon, and the coverings thrown over it before dark, the temperature should be not much below 70 degrees in the morning for two or three weeks, after which it will be gradually less, and then it becomes necessary, in order to maintain a good heat, to put a layer—or lining, as it is called—of fresh manure along one side and one end of the bed, and, after a week or two, when the frame again begins to get cool, to treat the other side and end in the same way. Another, but more laborious, method of maintaining the warmth, when nothing is planted in the bed, is to obtain as much fresh manure as was used in the first case, and, after leaving it for a week, make a new bed with it and the old hotbed mixed together, supposing there to be somewhere to put the contents of the frame during the change. The heat will not be so great as in the first bed, and as the season will be becoming more advanced, less will be necessary, but it will be a fair, moderate heat, and will last a good time, as long, perhaps, as it is really needed.

It is, however, perhaps as well to make up a new bed altogether in general circumstances, if a long succession of heat is wanted for rearing young plants in pots and boxes. If one has a cool, but frost-proof house or frame into which things can be transferred after early April, the bed, by putting more soil on the top, may be used for forcing radishes, lettuce, and such-like, or for cucumbers and marrows. There is little cost about the bed beyond the labour, as the manure will be just as useful afterwards as before, the frame having prevented most of it from being washed by the rain, and a wide board at the bottom will carry off the drippings from the sash.

ALGER PETTS.

SHRUBS WITH COLOURED STEMS.

Very pleasing effects can be created during the winter months by a judicious planting of shrubs with coloured stems, as these form a welcome contrast from the usual evergreen and deciduous species that are so much in evidence in most gardens.

Shrubs with coloured stems have come more into notice during recent years, but there are still many gardens that might be rendered more attractive by their inclusion. Masses planted near the waterside and by the side of drives are a source of attraction when there is but little colour to beautify the landscape. Those subjects with red, green, yellow, brown, and white stems are the most conspicuous, and should be principally utilised, for when seen on a bright winter's day the effect is very telling.

Few subjects can equal the dogwood for the brilliancy of its bark, and as it succeeds in almost all localities it should be freely planted. Cornus alba is one of the best to grow. C. sanguinea and C. stolonifera should also be planted, while the golden-stemmed form of the latter is a distinct acquisition.

Salix alba vitellina is an attractive red-stemmed willow, and S. ramulus aureus has lovely golden bark, which contrasts beautifully with the previous variety when the two are planted alternately in beds. A great advantage with these plants is that they thrive in almost any soil or situation, while damp, low-lying positions that are unsuitable for many subjects suit them admirably. In common with the dogwoods the willows should be cut down to the ground each spring, in April; a clean growth of three or four feet is then made during the season, with the result that the colour effect is not marred by a mass of old and badly-coloured wood near the base. There is no doubt that the practice of cutting right down to the base is the right one to adopt, as partial pruning does not give nearly such good results. Spiræa Douglasi should also be treated in this way; it will flower equally well in the summer, and the rich brown stems create a telling effect in the winter. Green is found in the common Broom (Cytisus scoparius), a beautiful subject for massing. Leycesteria formosa also possesses bright green stems of a distinct character.

Several brambles have picturesque white stems, notably Rubus biflorus, which grows to a height of twelve feet, and is known as the white-washed bramble. R. leucodermis is similarly effective, and R. lasiostylus also has white stems. Rosa lucida must not be omitted, as its bright red stems are a fine feature during the winter, but it should be planted in large masses to show off its full beauty. J. GARDNER.

Batsford Park Gardens.

Kerria japonica flore plena.—The uses to which this delightful golden-flowered shrub can be put are many. In the first place, it is in several districts valuable as a shrub in the open ground, where the rich green of its bark renders it, though leafless, almost as effective in winter as an evergreen; next, even in colder districts, it is a most desirable subject for training to a wall, the thorough ripening of the wood thus ensured being very favourable for the production of blossoms. Further, it occupies a foremost place among shrubs for forcing, as it readily lends itself to this mode of treatment, and the shoots wreathed with golden rose-like blossoms, form a bright and pleasing feature in the greenhouse, not the least notable item being the fact that they supply a tone of colour but little represented among their associates.—W. T.

THE SNOWDROP ANEMONE.

The number of hardy plants that bloom in May and June, and possess much beauty, is very large, but numerous as they unquestionably are, there would be some difficulty in finding many that could be described as more beautiful than the elegant snowdrop anemone, better known, perhaps, under its scientific name of Anemone sylvestris. Whether there are kinds that possess a greater charm than this wind-flower is a matter of but little consequence, for there are none that so closely approach it in appearance as to admit of a comparison being made that would be really useful.

It is sufficient for our present purpose to know that the snowdrop anemone is distinct in character, and exquisitely beautiful, and that it merits more attention than it has received. The plant grows to a height ranging from eight to eighteen inches, according to the conditions under which it is grown, the bright green leaves are elegantly divided, and the snow-white glistening flowers range from two to three inches in diameter. The general character of this anemone when in bloom is well shown in the accompanying illustration of a group of plants in the rock garden at Kew. Success may be achieved in its cultivation in the mixed border, provided the soil is of a suitable character, or can be adapted to the requirements of the plant, and positions can be given the groups where there will be no great risk of their being injured by neighbours of more robust growth. The rock garden, however, appears to be the most suitable place for the cultivation of the snowdrop anemone, but it should not, as is sometimes the case, be planted on the rockery. If the ledge on which it is located is relatively of considerable breadth, and contains a good depth of soil, the growth will be fairly good, but nowhere is so high a degree of development attained as when it is given a place, as at Kew, in a recess at the base of the rockery. The soil should be rather light, and contain a liberal proportion of decayed vegetable matter, and in the preparation of the stations spread about two inches of coarse grit and four inches of leaf-mould over the surface, and fork over the ground to a depth of twelve or fifteen inches. If the soil contains sufficient grit, give a dressing of leaf-mould only. The plants may be put in their positions in the course of the next month, and examples that are well established in pots will be preferable.

There are two varieties, and both are well worthy of a position in the rock garden or mixed border. One is A. sylvestris fl. pl., which is similar in growth to the specific form, and has double white flowers, the backs of the petals sometimes tinted with rose; and the other, A. sylvestris balcalensis, differs from the species in attaining about two-thirds the height, and in having single white flowers that are suffused with rose at the base of the petals.

THE SNOWDROP ANEMONE (Anemone sylvestris).
A beautiful species with snow-white flowers, as growing in the rock garden at Kew.

Philadelphus Lemoinei erectus.—This, one of the oldest of the garden varieties of mock orange raised by the late M. Lemoine, is, from a flowering point of view, still one of the very best. What is more, it is in the winter, when devoid of foliage, particularly bright and cheerful, the bark of the slender, upright shoots being of a warm red-brown colour. Now that more attention is devoted to the winter aspect of deciduous trees and shrubs than was at one time the case, this philadelphus, in its dual role, merits all that can be said in its favour. —K.

CALLAS.

The beautiful pure white spathes of the callas, or arum lilies as they are popularly designated, in contrast with the massive green leaves, show to great advantage in greenhouse and conservatory, and in bold arrangements in rooms during the winter and spring seasons.

Special efforts are generally made to have a good batch of flowering plants at Christmas, and again at Easter. I have noticed, in many instances, that the plants are sadly neglected for a time after the Christmas stock of spathes has been used up. Experienced cultivators do not make the mistake of neglecting the plants. I refer to the placing of the latter in very cool quarters direct from very warm ones; then a severe check is given. The plants are often subjected to a forcing temperature for a short period prior to Christmas, and it is such plants that suffer the greatest checks afterwards.

Of course, cultivators have different ways of treating their arums throughout the winter time. I like to give them warm greenhouse treatment after Christmas, and not be too free with the water, nor give any stimulant for a few weeks. In such circumstances I find that odd spathes show from time to time, and then, if placed in a slightly warmer house, a good batch of spathes are produced in time for Easter use; and it is while the flower stems are growing that I find it such an advantage to feed freely.

Well-grown plants will bear at least four spathes during the winter and spring seasons. I know some cultivators who assert that they produce six spathes. The plants are too often placed on the floors of glass structures, and are considerably weakened by want of light and air. G. B.

CULTIVATION OF LILIUMS.

Cultivation in Beds and Borders.

Suitable soil and moisture are very important matters in lily culture. Where they delight in moisture at the roots in summer, badly-drained soil, causing moisture to congregate round the bulbs in winter, will cause untold loss. To guard against this, even in light soils, it is desirable to place a layer of coarse sand below and on the top of the bulbs when planting.

As a rule we find the European lilies grow the best in British gardens, the ordinary soil of the herbaceous and shrubbery border suiting them. Most of the North American lilies, and some of those from Asia, will not thrive in soil containing lime in any appreciable quantity. In gardens where rhododendrons and the ericaceous shrubs thrive these lilies may be expected to succeed. To overcome the difficulty of growing rhododendrons the owners of many gardens where the soil contains lime have spent money freely in the purchase of soil and the preparation of borders and beds for their accommodation. The spaces between the rhododendrons may be planted with the peat-loving liliums—L. pardalinum, L. superbum, and L. auratum, for instance. Failing this a little trouble in the preparation of suitable soil is more than justified by the results obtained in gardens of lily lovers.

A very successful mode of culture is to plant bulbs of liliums in small groups between evergreen shrubs. These latter afford a little protection from frost to the young growths of kinds which push up above the soil early in the season, shade the lower portions of the stems from the sun, and prevent the ground drying up rapidly. Rhododendrons afford useful protection to L. auratum, L. pardalinum, L. superbum, and similar tall-growing lilies. Dwarf rhododendrons, kalmias, andromedas, etc., are shrubs among which may be planted L. rubellum, L. Grayi, L. canadense, L. philadelphicum, L. Parryi, L. washingtonianum, and L. Krameri.

The tall-growing, lime-loving lilies, L. sulphureum and L. Henryi, may be planted between such shrubs as Osmanthus aquifolium, Olearia Haasti, and Cistus laurifolius. Six of the best lilies for the herbaceous or mixed border are L. candidum, L. testaceum, L. croceum, L. szovitzianum (colchicum), L. umbellatum, and L. chalcedonicum.

Shady corners and pockets in the rockery are suitable for the smaller-growing lilies, while, if the rock garden covers a considerable area, with a setting of trees and shrubs, places can generally be found in the background where the taller-growing kinds will thrive.

A well-drained soil is necessary for lilies, particularly those from North America and Japan. When preparing soil for these use equal parts light sandy loam, peat, and leaf-mould, adding plenty of coarse sand or grit, wood ashes, and a little charcoal if available. Plenty of flaky leaf-mould should be used when planting all lily bulbs. The depth at which to plant the different species and varieties is important, as some root both from above (at the base of the stems) and below the bulbs, while others only root from below. The great difference in the size of the bulbs naturally necessitates planting them at varying depths. The following may be cited as instances of the depth to plant the bulbs: L. sulphureum and L. Henryi, which have large bulbs, and produce many stem roots, should be planted nine inches to one foot deep; four inches will be deep enough for the smaller bulbs of L. concolor and L. rubellum, which also root from the stem as well as below the bulb. In the case of the larger bulbs with no stem roots a covering of soil about three inches deep may be given; from one to two-inch covering being enough for the species in this group with small bulbs. Exception must be taken to this rule for L. giganteum and L. candidum, which may sometimes be seen in a very flourishing condition with the bulbs protruding out of the ground.

The more tender species, particularly the shallow-planted species, may be protected from frost in winter with a covering of coal ashes, sand, or half-decayed leaves. A mulching of half-decayed leaf-mould or manure from an old hotbed applied in early summer is very beneficial, as it keeps the ground moist and cool, and supplies nutriment to the stem roots.

When the bulbs are to be lifted and replanted it should be done in autumn, not later than the middle of November. Notable exceptions are L. candidum and L. testaceum, the planting of which is best done in August. The remarks also apply to the purchase of home-grown lilies, but the planting of imported Japanese bulbs is generally more satisfactory when done in early spring. Bulbs of L. auratum, L. speciosum, L. longiflorum, etc., arriving during the winter as a rule do better when potted up or placed in boxes in a cold frame and covered with leaf-mould. Planting out where they are to flower may be done towards the end of February or early March, by which time there should be plenty of young roots.

Cultivation in Pots.

Most liliums may be grown successfully in pots, though not more than ten or twelve species and varieties are grown to any appreciable extent under glass. The three most popular species and their numerous varieties for pot culture are L. longiflorum, L. auratum, and L. speciosum—or lancifolium, to use the market growers' name. It is difficult to say how many tens of thousands of bulbs of these three lilies are potted annually by market growers to supply the market with cut flowers, and by private growers for greenhouse decoration and cut flowers. As all three of these lilies produce stem roots freely the pots should not be filled more than two-thirds full of soil when potting, the remaining one-third being left for a top-dressing of rich soil later, when growths are pushing up. A suitable compost consists of two parts fibrous loam to one part leaf-mould, adding plenty of coarse sand. For L. auratum and L. speciosum half the above quantity of leaf-mould may be substituted by peat when available, possibly with advantage, by the private grower, but it is rather expensive material for the market grower to use.

As a precaution against loss the imported bulbs showing signs of disease should be dusted with a mixture of powdered charcoal and lime. Though not an absolute cure, this usually checks the disease sufficient to carry the plants over the flowering stage. Decay of the scales may be stopped by using powdered charcoal.

The size of the pot used depends on the size of the bulbs and the number placed in each pot. As a rule, it is more satisfactory (at all events, when used for greenhouse decoration), to grow three bulbs in a pot. In the case of L. longiflorum five bulbs in a ten-inch pot produces splendid results. On the other hand, large bulbs of the same species are valuable for decoration grown singly in six-inch pots.

The dwarf species, L. tenuifolium and L. rubellum, for example, are more satisfactory when cultivated in dwarf pots.

The question of what to grow in an unheated greenhouse is one often asked, particularly by amateurs. For such a purpose the lily is probably unsurpassed, for while, with one or two exceptions, all are perfectly hardy, the protection afforded improves the quality. The Madonna Lily (L. candidum), though perhaps most at home in the border of an old-fashioned garden, is also valuable in pots for the greenhouse, flowering six or eight weeks in advance of those outside.

The bulbs, when potted, may be placed in cold frames, and covered with leaf-soil, or plunged to the rim in ashes outside, with a covering of leaf-soil, and a sheet of galvanised iron or other suitable material placed in position to carry off heavy rains. To provide an early supply of flowers a sufficient quantity of L. longiflorum, L. speciosum, or L. auratum may be stood in a heated greenhouse when potted, and further batches be introduced from time to time as required. In due time, as the bulbs make roots and push up growths the covering must be removed, being only replaced at night if the shoots are advanced enough to suffer from late spring frosts.

L. sulphureum, L. Henryi, and L. giganteum are more at home planted in a greenhouse border than in pots, if the means exist to afford them such treatment. At Kew, in the Himalayan House, L. Henryi does remarkably well planted among the rhododendrons, and probably the finest specimen ever grown in this country was one in this house, where a single stem, ten feet high, bore fifty-seven flowers and buds. In No. 4 conservatory at Kew, growing in a bed among the camellias, a stem of L. sulphureum 11 feet 6 inches high several years ago produced ten flowers and buds.

In addition to those already named the following liliums are also grown in pots, to some extent, for greenhouse decoration: L. tigrinum and var. giganteum, L. pseudo-tigrinum, L. Browni, L. japonicum colchesterense, L. Hansoni, L. monodelphum (colchicum), and concolor forms.

Two or three tender lilies, which, though possibly hardy in sheltered spots of the sunny south and west, require the protection of a greenhouse in most localities, are L. nepalense, L. roseum (Thomsonianum), and L. philippinense.

A few years ago growers of the Trumpet Lily, L. longiflorum, for market, were put to considerable extra expense in their endeavours to obtain flowers from Christmas to Easter. Bulbs of L. Harrissi, from Bermuda, an early-flowering form of the trumpet lily, commanded high prices early in the season, but since the advent of the retarding process lily flowers can be readily obtained throughout the year. L. longiflorum, L. speciosum, and, in a lesser degree, L. auratum, are the three lilies generally favoured for retarding.

Kew. A. OSBORN.

APPLE WASHINGTON.

Among particularly handsome apples that possess high merit as dessert varieties Washington will always occupy a prominent position. As its name suggests, it was raised in America, and its introduction to our own gardens is due to the late Mr. Rivers. The large, regular, and handsome fruits have a rich yellow colouring that is brightly marked with mottlings of crimson. The richly-flavoured flesh is yellow-tinted and perfumed, and the variety is at its best from October to Christmas. Messrs. T. Rivers and Sons, of Sawbridgeworth, grow this apple remarkably well, and point out that it is a capital variety for pot culture, as, ripened under glass, the fruits are of fine size, colour, and flavour. As an orchard-house apple it is first-rate, and frequently figures in collections of ripe dessert fruit at the earlier summer exhibitions. In gardens it is not over-particular as to soil, but prefers a warm position.

OUR COMMONS.

In England, the ownership and property in the common land belongs to the lord of the manor, although rights over the common land are possessed by certain persons who hold land in the manor, and are known as Commoners.

The nature and origin of rights of common are derived from the old Germanic rights of common pasture on the folk-land.

The only land in England at present subject to common rights is waste land.

A very popular song in Lincolnshire in the year 1700 was one relating to the Inclosure Act.

"The lawyer he up to London is gone,
To get the Act passed before he returns;
If the lawyer ne'er returns, nor the Act any more,
It will be all the better for all our poor.

Before the Commons are ta'en in,
And you have hung your gates,
I very much fear
You will mortgage your estates.

But now the commons are ta'en in,
The cottages pulled down,
And Moggy's got na wool to spin
Her linsey-woolsey gown."

By permission we quote from the "Antiquary" of 1894 the following extract:

"In olden times there were no hedges or fences, but we learn that for boundaries objects were generally selected which on the one hand could be readily described, and on the other were not liable to change, rivers and brooks were preferred, and roads very frequently. When these were not available it was usual to set up crosses, so that the boundaries could be described as running from cross to cross and of such crosses the ordinary boundary stones in use at the present day are the degenerate representatives.

"Before the middle of the fifteenth century the open field system was in full operation in England, and the country was not cut up by hedgerows and fences as we see it to-day; from that date, however, the ancient arable lands were enclosed, and in many instances laid down as pasture, but we can see to this day the ridge furrow then known as 'lands'; when sheep-farming commenced these lands were broken up.

"The process of enclosure commenced about the year 1450. Roads which have been formed since the period of the enclosure may be known by the fact that they intersect both the hedgerows and the strips."

An old writer tells that we owe our hedges to the "Black Death"; this terrible pestilence so decimated the rural districts of England that arable land passed out of cultivation, and was turned into pasture, then hedges were planted to prevent the cattle from straying.

G. SIMMONDS.

THE SOAPWORTS.

Upwards of three dozen species go to make up the genus Saponaria, in which are included perennials, annuals, and biennials. Less than a dozen kinds are, however, in general cultivation, or found outside botanic gardens, and these, with one or two exceptions, are of perennial habit, and, further, constitute choice subjects for the rock garden. Their requirements are of a simple order, and, provided they are given an open and sunny position, a well-drained and sandy loam in which to grow, together with being so arranged that they are secure from excessive moisture in winter, they will be perfectly happy.

With regard to propagation, this is readily effected by division of the root-stock, the work being carried out in spring; also by means of cuttings and seeds. It may be explained that if slugs are present in a rock garden they make a determined raid upon these plants, and often there is great loss, hence the importance of making things uncomfortable for these garden pests, which do not seem to possess any redeeming quality.

Of very considerable decorative value is S. ocymoides, which produces in uninterrupted succession bright pink flowers throughout the season, while its trailing stems lend a light and elegant appearance to the plant. From the Pyrenees we have S. cœspitosa, whose rose-coloured flowers are freely produced from June to August. They are borne in loose umbels on stalks that seldom exceed six inches in height, while the habit of the plant is dwarf and tufted. Very similar to the foregoing, both in habit and colouring, is S. pulvinaris, which is found growing in stony and barren soil in its native habitat; as far as my experience goes, it is less susceptible to damp in winter than other species. S. bellidifolia must take rank as one of the choicest and most desirable, its heads of golden inflorescence being supported by tufts of ample foliage. Of lowly growth is S. Weinmanni, with flowers of a light purple shade. It seems to be identical with S. cœspitosa, with the exception of the flowers being several shades lighter in colouring that the last-named.

Everyone is acquainted with S. officinalis, which, as naturalised, is found growing in a wild state, not only in this country, but over the greater part of Europe. S. lutea and S. depressa extend the list, with yellow and purple flowers respectively.

The soapwarts of annual or biennial duration are of little value as garden plants, and, apart from S. calabrica, a floriferous and showy subject, with rose-coloured flowers, they are rarely, if ever, met with outside botanic gardens.

WALTER H. AGGETT.

APPLE WASHINGTON.

An American-raised, handsome and finely-flavoured dessert apple, introduced and finely grown by Messrs. T. Rivers and Sons, Sawbridgeworth.

RHODODENDRON NOBLEANUM.

This early-flowering hybrid between Rhododendron arboreum and R. caucasicum is one of the most conspicuous ornaments of the garden at the present time. In a Kingston garden there is a magnificent specimen that had over eighty heads of bloom open on New Year's Day, and this feast of colour is not an uncommon one, owing to the abnormal season through which we are passing. In R. nobleanum the corymbs of flowers are of medium size, and the individual blooms are carmine-rose, paler towards the base of the tube, with dark spots on the upper part of the segments. It is an old inmate of gardens, and as the flowers are always precocious it should be given a sheltered position from rough winds, which, more than anything, mar their beauty.

S.

HANDSOME DECORATIVE PLANTS FROM SEEDS.—I.

Many plants of a highly decorative and useful nature may be advantageously raised from seeds, and nowadays the choice is so large, and the variety of plants so numerous, that a comparatively few kinds only can be dealt with in the space at command.

These notes are not written as an argument against the orthodox method of raising plants from cuttings, or by other recognised methods of propagation, but in the hope that they may prove helpful to those who are unable to raise plants for home and house decoration in the usual and, more often than not, complex way. One great advantage in raising this class of plants from seed is that with ordinary care they are thus very easily grown.

Most of the subjects mentioned may be raised in gentle heat, such as may be obtained in a hotbed, by placing a frame over a mixture of fresh stable manure and leaves in about equal parts, prepared in the usual way, early in the season. Under such conditions the seedlings soon appear, and may be potted off as they become ready for that operation, using a compost somewhat coarser in texture than that in which the seed was sown. Great care must be exercised in preparing the soil and pots or pans beforehand. All the receptacles should be scrupulously clean, and the soil, when mixed, be in a friable condition—that is, neither wet nor dry. A compost of about equal parts of fibrous loam, leaf-mould, and peat, with a good addition of silver sand, will answer admirably in which to sow the seeds. Pass the whole through a quarter-inch or three-eighths sieve, and fill the pots and pans to within an inch or so of the rims. In the case of very fine seeds no covering will be necessary beyond a very light sprinkling of fine sand; larger seeds may be covered with about a quarter of an inch of soil, not more.

Abutilons and Browallias.

Hybrid abutilons are of very easy culture, and the seeds, if sown early, will produce plants that will bloom profusely during the current year. The seedlings are usually very vigorous, and after one or two stoppings the resulting growths quickly become studded with buds, and bear blossoms, which, when fully expanded, open to three or more inches in diameter. For house and conservatory use these are invaluable During the second season of growth these—if too large for indoor use—may be used with advantage as dot plants in the flower garden and shrubberies.

Browallias are extremely pretty, free flowering, and useful, affording a display of colour during the autumn and winter months. B. elata grandiflora—really a half-hardy annual—is a useful variety for greenhouse cultivation, producing very freely flowers pale blue in colour. The plants grow to a height of about fifteen inches, but should dwarfer plants be thought desirable, the young growths may be stopped as often as may be thought desirable. By making occasional sowings this variety may be had in flower during the greater part of the year. B. speciosa major is an excellent winter-blooming variety, producing large blue flowers, much deeper in colour than B. elata grandiflora, if the strain is a good one.

Celosias.

Celosia plumosa affords beautiful plants for conservatory decoration, making a very effective display during the latter part of the summer and in early autumn. These require a fairly high temperature during their growing period, and liberal treatment in the way of feeding, but should not be grown in large pots, or the plants become coarse rather than elegant. When the flower spikes or plumes are about half expanded the plants may be gradually hardened off, and afterwards, if a sheltered sunny spot out of doors can be given them for a week or two, the brilliancy of the colouring will be very considerably heightened. This is a plan we ourselves have followed for many years, and have invariably found the plants much improved by this treatment, and lasting much longer in good condition.

Coleus.

Coleus hybrids, the seeds of which, if sown early, will produce large plants during the first season, are rightly classed with the most beautiful and useful of our soft-wooded ornamental foliaged plants. From seeds many new and distinct varieties may be raised. To obtain good plants by midsummer seeds should be sown as early in the year as possible in pans of light rich soil, covering the seeds but lightly, and shading until germination takes place. Prick off the seedlings as soon as they are large enough to handle into other pots or pans, and then keep growing in a brisk heat until the roots have obtained a good hold of the new soil; afterwards they will succeed well in a lower temperature.

Coleus thyrsoideus is an extremely pretty free-flowering species, growing to a height of eighteen inches or two feet, the branches terminating in racemes of bright blue flowers during the winter and spring months, at which time the plants will do well in an intermediate temperature; in fact, too much heat at this stage is decidedly injurious to the flower spikes. Upon all favourable occasions plenty of air may be given, avoiding cold draughts. This coleus may be fed with artificial manures pretty frequently, and an occasional watering with clear soot water will aid in keeping the foliage green and healthy after the pots are well filled with roots. During the growing period little or no shading should be given, the plants delighting in plenty of bright sunshine. During the summer and early autumn we have grown C. thyrsoideus and poinsettias in the same structure, giving both of these precisely the same treatment with unvarying success.

W. HEDLEY WARREN.

Aston Clinton Gardens, Tring.

Iris stylosa.—This beautiful plant has been producing its flowers for several weeks, and will continue for some time. It deserves to be grown more extensively. In cold districts it requires shelter, and the foot of a south wall, either that of a dwelling-house, or preferably, a greenhouse, is an ideal position for it, if given light soil to grow in. In sheltered parts of the country, where the soil is light and well drained, it will thrive in an open border; but the former situations will be found most suitable generally.—T. B. FIELD, Wych Cross Place Gardens.

POT CULTURE OF APPLES AND PEARS.

I was much interested in the pithy and timely article on this subject by Mr. James Hudson, V.M.H., and also in the excellent photographs of the two pot-grown trees bearing fruits, in the issue of the GARDENERS' MAGAZINE for December 14.

In many gardens there is ample room for pot-grown apples and pears. All specimens so grown are under the direct control of the cultivator, therefore, while the flowers are open, they can be protected from frosts.

I was glad to see pear Durondeau and apple Ribston Pippin included in Mr. Hudson's list. Both are excellent varieties for the purpose, and amateur cultivators should not fail to grow them.

Where more substantial houses cannot be spared for the accommodation of fruit trees in pots, cheap ones made of wood may be erected in sections. They are easily and quickly put up, and as readily taken down. They are useful for many kinds of plants in the autumn time, as well as fruit trees when the latter should be placed in them. It is necessary to keep these houses well painted; then they will last many years.

Some years ago I inspected a rather large wooden orchard house, in which peaches and nectarines were planted permanently and grown as standards. Apples, pears, and cherries in pots were placed in this structure in due season, and a most interesting collection they formed. The roof was so constructed that it could be removed, or at least, the glazed lights, and thus the trees were exposed at will to the weather.

G. B.

CLEMATIS BALEARICA.

This is the earliest of all the clematis family to flower in the open air, coming into bloom in the south-west before January is out, and a blossom or two is generally discernible before the New Year has commenced. Although its whitish flowers, spotted in the interior with purple, cannot be said to be particularly showy, it is a valuable plant on account of its early blooming. It is a very rapid grower, ascending to the eaves of a house, a height of over twenty feet, in a few years, while in a friend's garden a plant has clambered up into a variegated tulip tree to a height exceeding twenty-five feet; in fact, it may be considered almost as good a tree climber as Clematis montana. The flowers are borne in great profusion, having as companions few open-air blossoms besides the winter jasmine, Chimonanthus fragrans, the witch hazel, Prunus Davidiana, Iris stylosa, and Christmas roses. The feathery, grey seed-vessels, though perhaps scarcely so effective as those of the common Traveller's Joy (Clematis vitalba), have a pretty appearance during the autumn months. It is also known as Clematis calycina.

This clematis is often confounded with C. cirrhosa, which bears flowers of the same size and colour, but with no spots in the interior. This, however, is much later in blooming, its first blossoms expanding just as the last flowers of C. balearica are fading. C. cirrhosa is by far the oldest occupant of our gardens, having been introduced into this country more than three hundred years ago, whereas C. balearica has not been known for much over one hundred years. Both species should undoubtedly be planted in gardens, as they extend the flowering season of their family from the winter days almost until the time that the Mountain Clematis (C. montana) spreads its veil of ivory-white star blossoms in the late spring.

WYNDHAM FITZHERBERT.

South Devon.

CHRYSANTHEMUM RED CAP.

The market grower has the habit of contracting names of plants and flowers, consequently the man in the street sometimes wonders what plant or flower is intended by certain expressions common in the markets. "Cues" for cucumbers, "gipsy" for gypsophila, and "pellies" for pelargoniums are examples of such contraction, and are generally well understood; but there are others not easily recognised. A chrysanthemum that has found great favour with growers who produce dwarf and beautiful pot plants is Caprice du Printemps, and, as in the case of so many chrysanthemums that have been grown widely, it has sported, and given many colour variations distinct from its own rosy-pink hue. It was not long before the market man shortened the title of this variety by dropping the second and third words and cutting the first one in half, until instead of offering or requiring plants of Caprice du Printemps, he sold or bought "Caps." With this abbreviation for a base the market men prefixed colour adjectives as needed, and so we have White Cap, Yellow Cap, and Red Cap, all varieties of Caprice du Printemps, and differing only in colour.

These are all splendid sorts for greenhouse and conservatory decoration, grown in 48 or 32-sized pots, and they are very fine when, in such pots, they carry from eighteen to thirty well-developed blooms, and stand about eighteen inches high. It is a good plan to insert the cuttings at the end of March or early in April, in a warm frame. These are potted off singly as soon as rooted, and stopped as soon as established. From thumbs to 60-sized pots is the next move, and early in July the last potting should be done, and the shoots must be only stopped once after the final potting, though they may have been stopped two or three times previously.

One or two special points are worth remembering, and these are to plunge the pots, out of doors, to their rims in ashes as soon as possible after the final potting; to keep the plants at all times free from insect pests; to never allow the soil to become dry; to disbud to one flower per growth; and to commence feeding as soon as the flower buds have set, making a fairly free use of clear soot water, so that the leaves may be kept a deep green colour. Many other chrysanthemums, especially those bearing compact, medium-sized blooms, may be cultivated in this fashion, and the accompanying illustration of Red Cap, as grown at their Feltham Nurseries by Messrs. Jas. Veitch and Sons, will serve as a model for those who propose to cultivate these useful dwarf chrysanthemums for conservatory and corridor decoration.

C.

The Blue Sow Thistle.—Mulgedium alpinum, the blue sow thistle, is most handsome, though possibly considered by many a little coarse in its aspect. Yet it is a good border subject, giving little trouble when in a dry soil, and it looks well in a large border among other tall perennials. It may also be planted with advantage in the wild garden or in openings in the woods, where it grows to a height of three or four feet, and affords a number of blue flowers, of considerable depth of shade, in clusters. The leaves are on long stems. Somewhat coarse on the whole, the alpine blue sow thistle is worth growing in many places, and the colour is by no means too plentiful among composites in bloom in late summer, when it flowers. M. alpinum may be increased by division or seeds.—S. ARNOTT.

THE ALPINE HOUSE AT KEW.

Throughout the spring months this house forms quite a centre of attraction by reason of the number of floral gems that are sure to be found therein, and even as early as the middle of January it contains much to admire.

Some of the species of crocus are now particularly bright and cheerful, among them being C. chrysanthus, yellow, with dark striping inside; C. Sieberi, mauve; C. Imperati, purple and fawn, with dark markings on the exterior; C. Fleischeri, pure white, with orange-red stigmata; C. biflorus, white, with dark feathery outside; and C. marathonensis, white. Snowdrops, too, are numerous, Galanthus byzantinus, G. robustus, G. Fosteri major, G. Elwesi, and G. Whittalli being in bloom.

A few saxifragas which serve as harbingers of many more to follow include the pure white S. Burseriana grandiflora and S. Boydi alba; the pale yellow S. Ferdinand Coburgi, and that charming species, S. Griesbachi.

The brightest feature of all is furnished by masses of bulbous iris, notably the golden-yellow Iris Danfordiæ, the bright blue I. histroides major, and I. stenophylla, whose flowers are lilac, blotched with purple. Anemones include A. hepatica and its white variety, the lovely blue A. blanda atrocærulea, and A. pulsatilla Halleri, a deep violet-blue variety.

Other subjects that contribute their share to the floral display are Adonis amurensis, whose pretty fern-like leaves serve to set off the golden blossoms; Arabis alpina, with tiny white flowers; Leucojum vernum, the Spring Snowflake; the new Indian Primrose—Primula Winteri; Scilla sibirica, and its white variety, and Sternbergia Fischeriana.

K.

MAGNOLIAS

The hardy evergreen magnolia should be grown in our gardens more than at the present time. It is very rare that one sees fine old specimens of M. grandiflora. In one garden in Hampshire, of which I had charge for many years, there was a row of trees in one border, and several growing near walls in the kitchen garden—which was six acres in extent. The stems of some of these trees, at 2ft. from the ground, measured 3ft. in circumference; several had been badly beaten about by strong winds, but every year there was a fine crop of huge flowers.

Now, these old trees did not make much new wood yearly, but it all matured owing to the full exposure of the branches to light, sunshine, and air. Annual top-dressings of decayed manure and loam, mixed, were needed to maintain the strength of the trees, and they were always satisfactory. Some of the trees were growing in a very moist soil, while others were in a very dry one, but there was little difference in the amount of new growth made each year, and none in the matter of flowering. Those trees in the moist soil made a little more growth, but it was scarcely noticeable.

In the same district were other specimens of Magnolia grandiflora. These were, however, in positions that were none too light, and the sunshine only reached them for a few hours in the early morning. Flowers on these trees were scarce, indeed, but the foliage was much finer than on the specimens I have first referred to. Every year long-jointed shoots grew, and these suffered in severe weather. The fully-exposed trees were the most satisfactory.

B.

CHRYSANTHEMUM RED CAP.

A deep red-coloured sport from Chrysanthemum Caprice du Printemps. The plant represented was grown in a 5in. pot by Messrs. Jas. Veitch and Sons, and exhibited by them last autumn.

ROSE ROSE QUEEN.

Unquestionably this rose is a very beautiful one, and admirably adapted for forcing, as under skilful cultivation it produces splendid broad-petalled, large rich rose-coloured blooms on long stems. It is an American-raised rose, and was put into commerce by the Messrs. E. G. Hill Company, of Indiana, U.S.A., after having been grown very extensively for the cut flower market. Mr. W. E. Wallace, of Eaton Bray, Dunstable, ever on the alert for improvements in roses and perpetual carnations, entered largely upon its cultivation under glass. During a visit to the United States he was much struck by the beauty and usefulness of the variety, and on his return very substantially increased his stock: indeed, we believe he grew fifteen thousand plants this last season. On March 19 last Mr. Wallace exhibited some grand flowers at a meeting of the Royal Horticultural Society at Westminster; the blooms were greatly admired for their form, substance, and colour, and an Award of Merit was granted.

DAHLIAS IN 1913.

It may appear to many readers somewhat early to talk about the dahlia in January, and perhaps it is to the amateur who divides his roots in April, and plants them straight away in their flowering quarters, but such good people have but a mild idea of dahlia growing. There are many phases of dahlia cultivation quite unknown to many people who are even interested in the flower, and they have little idea of the large amount of work that has to be done by the dahlia specialists before the plants reach their hands for planting purposes in the month of May.

I am under the impression that the prospects of the dahlia were never brighter than now, and I might also say these prospects are shared by other countries, for the export of pot tubers must be a record by the close of the season in April. The pot roots have been shipped in hundreds, yes, and thousands, to Japan, the United States, South Africa, Australia, India, and the Straits Settlements, to say nothing of the European countries.

Surely this points to bright prospects for the coming season.

The National Dahlia Society, too, appears to be imbued with renewed energy, and will hold a conference next month, at which some interesting subjects are to be dealt with, particulars of which will appear in these pages as soon as arrangements for

ROSE ROSE QUEEN.

A deep reddish-rose, H.T. variety, raised in America. It gained an A.M., R.H.S., on March 19, 1912, when exhibited by Mr. W. E. Wallace, of Eaton Bray, Dunstable.

the papers to be read and the place of meeting are complete.

The past two years cannot be described as good dahlia seasons, for in 1911 the dry weather that went on without a break week after week was not conducive to the rapid growth so essential to the dahlia, and no doubt many people were disgusted with the results obtained after all their trouble with the water-can; 1912 was little better, the cold, wet, sunless summer, with an almost Arctic August was not suited to the dahlia, and again the results were not so good as they might have been, though it must be admitted that show flowers were up to their usual form. Anyway, we are looking forward to a better growing season in 1913.

It is advisable at the present time to look over the dahlia roots in their storage, for they did not ripen off well and naturally last autumn, and where they were lifted as soon as the frost cut them down, and stored without any drying off previously, I fear many of the roots will not have kept well, but if they are examined now, and the decaying portions of the tubers are cut off, the crowns will be saved, and the partial loss of the tubers will matter but little. Even the turning over of the tubers will do them good, especially if they are at all damp, while if they are shrinking badly they can be moistened, and, after drying out again, be placed back in store.

Those specialists who have to produce thousands of plants for next April and May are already at work, and I have no doubt they have thousands of cuttings in their propagating houses already, but these early cuttings are for the production of pot-root tubers, and are not usually sold as green plants. It will, however, be as well to emphasise the necessity of growing or obtaining good plants ready for planting time, and these can be grown on steadily in frames protected from frosts, with little trouble, but the plants must be kept growing, for once they get hard their prospect of success has gone altogether.

J. B. RIDING.

LINDENBERGIA GRANDIFLORA.

This yellow-flowered labiate, which was given an Award of Merit on January 7, is of considerable decorative value, a great point in its favour being the fact that it continues to bloom during the late autumn and winter months. It is by no means a novelty, having been introduced about a dozen years ago, but though it has been several times exhibited it was only this year that it was honoured by an Award of Merit, possibly owing to it not having been submitted to the Floral Committee.

In a state of nature it occurs in a considerable tract of the Himalaya, from Simla to Bhotan. In this country it must be regarded solely as a greenhouse plant, and succeeds best when raised from cuttings of the young growing shoots in the spring, and the young plants are grown on as salvias and many other subjects are. Bushy plants about a couple of feet in height will bear a large quantity of blossoms, which are individually very much like those of the common musk, but considerably larger.

After the plants have done flowering they may be cut back and kept somewhat drier for a short time, then with increased heat and moisture they will push out a considerable number of young shoots, and these taken as cuttings will strike root in a very short time if inserted in pots of sandy soil, and placed in a close propagating case in a gentle heat. Care should be taken not to leave them therein after they are struck, otherwise they will run up weakly. Ordinary potting compost, such as a mixture of fibrous loam, well-decayed manure, leaf-mould, and sharp silver sand, will suit this lindenbergia.

S. W.

HYDRANGEAS AS TERRACE PLANTS.

The use of bold specimen plants in tubs for terrace decoration is no new matter, but with the advent of wild gardening—so-called, semi-wild gardening, and a freer and less formal style in our methods of garden design and decoration, there was a decline in their use. Their value has, however, never been lost sight of in these pages, and the growing popularity of shrubs in tubs, and specimen pot plants on terraces, by the sides of steps, and in other places, where they are in keeping with the surroundings, is largely due to the continued advocacy of their claims in the GARDENERS' MAGAZINE. Scented-leaved pelargoniums, agaves, agapanthus, lemon-scented verbena, bays, and oranges are a few of the more popular subjects, but fuchsias, zonal pelargoniums, marguerites, and chrysanthemums are often pressed into service, and, perhaps, hydrangeas are most popular of all. We have, on several occasions, indicated the few simple cultural details necessary to success, and have at various times given illustrations of the effective use of hydrangeas in tubs. In the present issue we show how large specimens are placed with great effect during the summer by the terrace steps (of grass) at Downside, Leatherhead, where Mr. W. Mease, gardener to Alfred Tate, Esq., grows roses, chrysanthemums, and many other things so well.

SPECIMEN HYDRANGEAS BY THE TERRACE STEPS AT DOWNSIDE, LEATHERHEAD, THE RESIDENCE OF ALFRED TATE, ESQ.

SOWING SMALL SEEDS OF GREENHOUSE PLANTS.

At this season of the year there are many things that require attention, but I doubt very much if there are any that require greater care than sowing seeds of choice greenhouse subjects to produce plants that are intended to bloom later in the year. Some of these seeds are very minute indeed, and, therefore, require special treatment to induce them to germinate freely, for not only must the soil in which they are sown be of a suitable kind, but the temperature in which they are placed after sowing be such as to induce free germination.

There is far more art in successfully raising early plants from seed than some who are unacquainted with the facts would believe. Some seeds, if covered too deeply, will fail to germinate, while others, if placed in too high a temperature, or sown in the wrong class of soil, refuse to grow, and not a few fail to produce a stock of plants through failure to keep the soil in a proper condition as regards moisture. Before commencing seed sowing it is well to prepare the compost for that purpose. The pots, pans, or boxes used should be well drained, and, after placing in them about two inches of rough material, the fine soil should be put on the top. For these very small seeds the soil should be passed through a fine sieve, and afterwards watered, so as to settle it. When the superfluous water has drained away the boxes, etc., should be carried into the propagating house and allowed to stand until the following day, by which time the soil will be in a fit condition to receive the seed.

Sowing.

We often notice that when seeds are self-sown the majority germinate, whereas when they are sown by us, in many instances, they fail to grow, and seedsmen are often blamed for supplying old or inferior seeds. It is well known that some seeds possess a greater vitality than others, and in not a few instances the best results are obtained by sowing the seeds as soon as gathered. But this is not possible in all cases, so we must try and follow Nature as best we can.

I remember well when the seeds of Primula japonica were first offered that but few people were able to induce more than about five per cent. to germinate. They were sown in heat, in cold frames, out of doors, and in a variety of places; still they refused to grow, but, after a time, when plants were allowed to stand and seed themselves, the young plants came up in such numbers as to become quite a pest, covering everything just like common weeds and in some places the seed pods had to be removed before the seed ripened to prevent the trouble of getting rid of the young plants.

Now such things should teach us a lesson as to the way of sowing and the after-treatment of such plants and seeds. Many make up a hotbed, and on this they stand the boxes or pans after the seeds are sown with a view of getting them to germinate more quickly. These beds, unless great care is exercised, frequently become so hot as to kill the seeds, except a few round the edges of the boxes, etc. Again, when the seeds are sown on the surface of the soil, on no account should the boxes be exposed to the bright sunlight, as this would cause the tender seedlings to wither up in a short time, and when this happens the person in charge is at a loss to account for the failure, and blames the seedsmen, when, in reality, it is his own fault. Half an hour of bright sun shining direct on small tender seedlings would be sufficient to cause them to wither, especially should the soil be in the least dry. To guard against this possibility the house or frame should be shaded from the bright sun, but, on the other hand, the shade should not be so dense as to cause the plants to become drawn.

The seeds of the majority of greenhouse plants do not require a great amount of heat to cause them to germinate; in fact, a temperature of from 60 to 65 degrees is ample for most of them, and if subjected to a higher degree of heat they do not grow so well.

There is another thing that should be guarded against, and that is sowing too thickly, for when the plants touch each other almost as soon as they are through the soil they hold moisture, and damp off, and when this damping off has once set in there is often a difficulty in checking it. The seeds of some kinds of plants are so minute that it is almost impossible to see them, and they are issued in such tiny packets that one has to be very careful they do not all come out at once. If it takes a little longer to separate them the time is well expended if the seeds are sown evenly over the surface of the soil. There are, of course, some seeds of much larger size, and these should be sown at various depths, according to their class, but with even the largest of them it will not be necessary to place them more than two inches deep. Some kinds germinate much quicker than others, for while some only take a few days, others require two or three weeks. When sowing is finished it is a good plan to cover the seeds with a sheet of glass, and over this put a sheet of brown paper. This will prevent evaporation and save watering. The paper should be removed at night, after the seeds have been sown two or three days, in case any plants make their appearance, and all ought to be examined daily afterwards.

When the young seedlings appear guard against snails, woodlice, and the like, as these troublesome pests often do a great amount of damage before they are detected. On no account allow the soil to become dry, but at the same time avoid too much moisture, as this would cause damping. Seedlings should be pricked out as soon as large enough to handle, but must afterwards be kept in the same temperature until re-established.

H. C. PRINSEP.

"Sweet Peas and Their Cultivation," by C. H. Curtis, is a compact and very readable Guide to the culture of this lovely and fragrant flower. Mr. Curtis, who is Hon. Secretary of the National Sweet Pea Society, deals fully and practically with its varieties, culture, and diseases. The book is well illustrated, and can be obtained from our publisher for 1s. 2d. (cloth 1s. 9d.), post free.

SOME JANUARY ROSE NOTES.

If the weather continues mild and open there is no need to cease planting, but I always prefer autumn or early spring planting to mid-winter. At present the soil is several degrees warmer than is seasonable, and planting may still go on whilst this condition continues. The various mixtures of soil and manures, intended to enrich our roses early in the spring, should be turned over a few times before use. This will not only incorporate the ingredients more evenly, but turning it admits air, disturbs many insects, and assists the uniform decay of the whole.

Mulching and Surface Digging.

Personally I prefer mulching early in the year rather than during autumn. Many mulch with the idea of protection, but I have not found this to be useful; a wet mulch, suddenly snapped by a sharp frost, is no protection whatever, and I prefer the plants to be open and dry. Where the ground is being improved by mulchings I would not place these around the base of the plants for this reason; earth is better than any form of manure around this part during winter. Besides, the best of the feeding roots are a little away from the base, and it is these that we want to assist.

Light or shallow digging between the plants will help to keep the ground sweet and clean. Do this now, before mulching, and then turn it over again directly after the pruning is done. This will till the ground, get the manure just under the surface where wanted, and leave the top in a good condition for the late spring and summer hoeings, to which I attach great importance.

Where planting has to be delayed until spring, have the ground prepared as soon as possible. It is better when allowed to settle a little than to plant upon loose, freshly moved soil. In this connection it is difficult to advise definitely, and each must decide for himself according to the condition and nature of the soil; but never plant while the soil clogs to the tools and boots. It is far better to lay the plants in by the roots and wait for a more favourable opportunity.

Shortening Standard Brier Growths.

The shoulders of standard briers, containing live rose buds inserted last summer, may be cut back to within six inches or so of the bud. This will allow of one getting among them better, and there is no reason why they should not be cut back thus early. We leave a little more growth beyond the bud, in order that some of the brier eyes may break into new growth, and encourage a better flow of sap to reach the rose bud. The rose eyes alone do not draw up enough sap to give themselves a fair start, and we find better results by encouraging the flow of sap in this way, and gradually reducing the brier growth as the rose progresses. The brier stems can be set up straight, and the ground between them dug over fairly deep, for there will be few roots near to the surface among standard briers of only one season's growth.

Supports for Standard Roses.

It is very necessary to afford efficient support for standards, also to the heavy-topped dwarf and pillar roses. Without this they cannot fail to sway about, which is always harmful. Stakes of many sizes may be used, but they seldom last more than a couple of seasons, unless of an unsightly and clumsy size. Iron stakes are best, and it is a capital plan to use galvanised gas

"Seeds That Grow"
Burpee's

Are supplied each season direct to many more planters than are the seeds of any other brand. BURPEE'S SEEDS are known the world over as the best it is possible to produce, and are acknowledged the American Standard of Excellence.

In thirty-six years of successful seed selling we have introduced more Novelties that are now in general cultivation than have any three other firms. We produce Selected Stocks upon our own seed farms in Pennsylvania, New Jersey, and California, while FORDHOOK FARMS are famous as the largest trial grounds in America. No Government Experimental Station attempts such complete trials each season, and the information here obtained is of incalculable benefit to planters everywhere.

Each season we travel more than thirty thousand miles to personally inspect our growing crops, and yet never travel a single mile to solicit an order! We ask, however, that you allow our SILENT SALESMAN to have your careful attention in the quiet of your own home.

Simply send us your address plainly written, and kindly state where you saw this advertisement. Then by first mail you will receive

The Burpee-Annual for 1913

A bright new book of 180 pages, it pictures by pen and pencil all that is Best in Seeds, and tells the plain truth. While embellished with coloured covers and plates painted from Nature it is A SAFE GUIDE—entirely free from exaggeration.

Shall we send you a copy? If so, write TO-DAY! A postal card will do—and you will not be annoyed by any "follow-up" letters.

or water piping, painting this over to preserve the metal and check any undue influence of frost. Though a trifle expensive at first, they last for a generation, and never rot off at the ground line—a weakness that makes the usual stakes and sticks so unreliable at the very time when most wanted. Great strength with desirable neatness can be had thus.

No time should be lost in potting up a few extra plants to use for filling blanks that are found when pruning. There are almost certain to be some of these, and it is safer to have pot plants to take their places than to move any so late from the open ground. I would have a few standards, climbers, and ordinary dwarfs prepared in this way. Even if not wanted, they will be useful to grow for flowering in pots the following winter, and they are always a little better than freshly-potted plants for forcing.

Delay the planting of dwarf stocks for budding upon until the end of next month, when a few hints upon this matter may appear.

Roses in Pots.

The main batch of roses under glass will need careful overhauling this month, and any repotting should be done at once. A somewhat coarser compost and much firmer potting than usually adopted will be found advisable. Although good drainage is very essential, I have frequently come across instances where this has been overdone, more especially in the use of far more crocks than were necessary. Half the quantity can be made effective if we take more care in placing them, and, seeing that crocks contain no element of plant food whatever, it seems a pity to occupy unnecessary space with them. I have found nothing better than a few half-inch bones, as these provide ample drainage, while feeding the lower roots at the same time, and so make a practice of placing a few over the three or four carefully-laid crocks.

Always remove as much of the old soil as possible when repotting, and be sure the old soil and roots are moist when placing the new soil around them. If the roots can be separated a little sand and some of the fresh compost worked well in among them they will start better and stronger. Any tendency towards looseness of soil should be avoided by ramming it down with a label or piece of wood between the old ball and the pot. I have found a somewhat coarse compost, rammed down fairly firm, much better than one of a finer character.

Pruning roses in pots is rather different to the same operation in the open. The centre of the plants need more care in thinning, and one should study the direction the strongest eyes are taking if a plant with any pretentions to shape is wanted. But so much depends upon the character of each variety's growth, and whether it is a well-formed plant with a few good blossoms or a greater quantity of flowers independent of the plant's appearance that is wanted.

House all pot roses, and prune them at the same time. They can be brought on in distinct batches by removing them to warmer quarters as wanted. Any fairly light shed will answer the purpose, the main thing being to keep the wood from severe frost, and to protect the pots. One does not obtain the same pleasing results from wood that has been openly exposed to severe frost as that receiving this little, but most important, protection.

Let us once more advise steadiness in forcing, and cleanliness in all ways from the very first. Roses may be hurried a little after the growth has become well advanced, but to force them from the outset is not satisfactory.

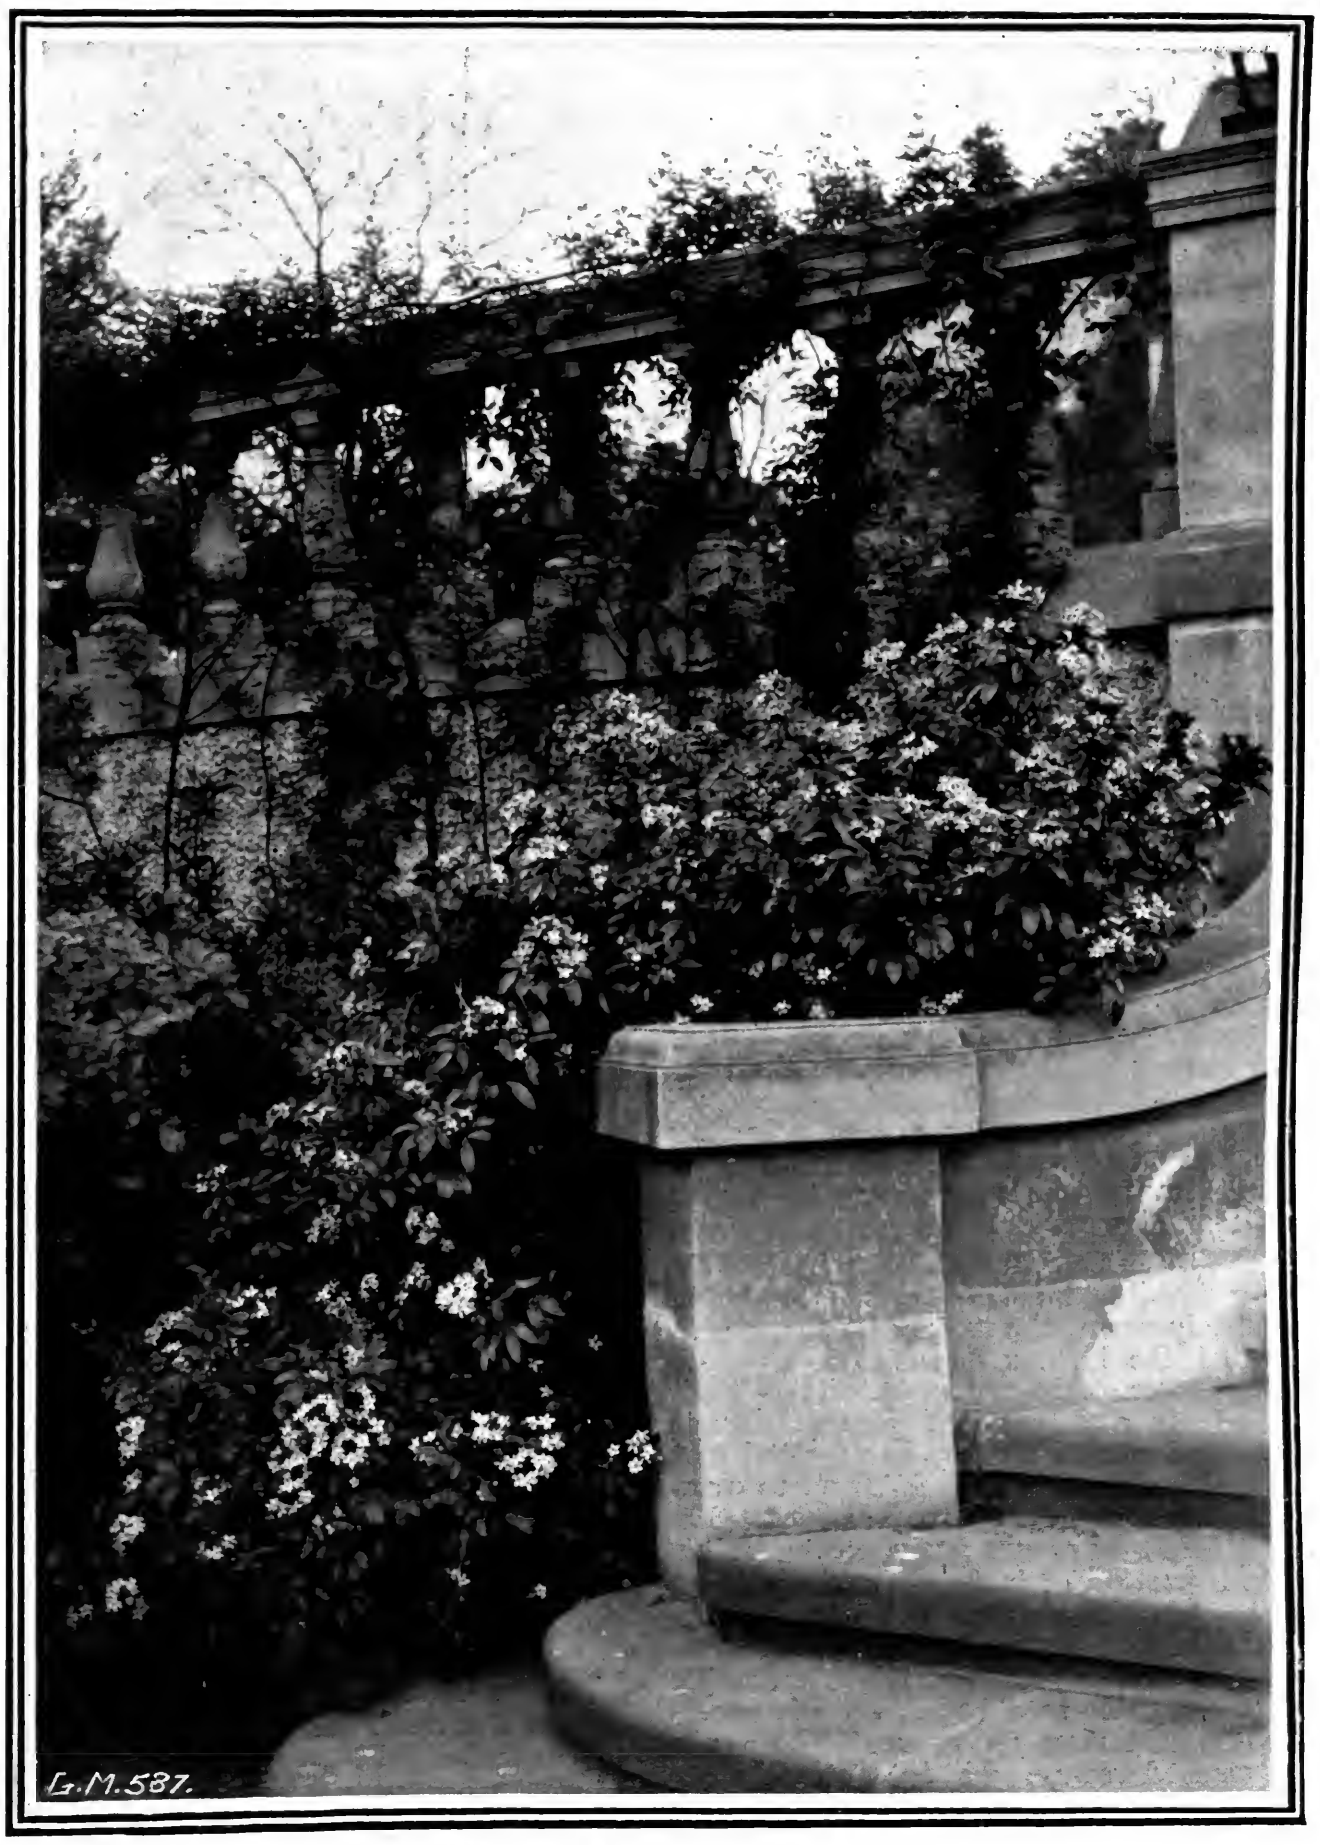
A. P.

CHOISYA TERNATA.

Choisya ternata is comparatively well known, as it is one of our handsomest evergreen shrubs, and although not absolutely hardy in every locality, it nevertheless enjoys a full share of recognition in cold districts as a wall shrub, for which purpose it is well adapted. In the young state the point of the branches are frequently damaged by frost, owing to their unripened state, but as the tree becomes older it naturally produces shorter growths, and as these ripen earlier they more frequently pass through the winter uninjured. In mild localities and coastal districts generally Choisya ternata forms a dense bush in the open, some six to eight feet in height, producing the white orange-like blossoms in loose, branched heads from the axils of the leaves near the points of the branches. The flowers have a delicate fragrance, like hawthorn, while the foliage, when handled or bruised, also emits a pleasant odour.

Branches of this plant, when cut, are admirable for arranging with various flowers, as the rich glossy green leaves contrast effectively, and when cut in winter and spring they last for several weeks in a fresh condition. This choisya flowers during April and May, and again in September and October. The display during the past autumn was quite equal to that usually produced in spring. Choisya ternata is one of the finest shrubs for limestone or chalky soils, on which it makes rapid growth. It is readily propagated by cuttings inserted in the open ground during October, or by layers put down at the same season, or in spring.

Coombe Court Gardens. T. SMITH.



CHOISYA TERNATA.

A beautiful evergreen shrub with white fragrant flowers.

Primula malacoides is very beautiful; its elegant spikes of rose-lilac flowers give it a great charm, and for a small table it is most useful. One serious drawback to this primula is that, although it needs a good amount of water, the supply, unless given very carefully, will cause the plant to damp off at the collar wholesale in a few days. The old double white primula is still one of the best, and the improved form, Beauty of Exeter, is very useful for buttonholes when three flowers are wired together with a frond of Adiantum cuneatum as a background.—LEWIS SMITH.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEED SOWING.—Many of the winter-flowering cypripediums will have matured their seeds, and others will ripen during the next few weeks. It is desirable that a portion of the seeds should be sown at whatever season they may ripen, immediately the pod bursts, the remainder being made secure and held over for more favourable conditions. It is not always convenient to find suitable seed beds ready to take the seed, or plants that will not need repotting during the coming season, although I advocate sowing on the compost of plants that have been undisturbed for a long period. We have to prepare suitable seed beds as a rule before any quantity of seeds are sown, but it will usually be observed that the seed germinates much more rapidly on the surface of the soil about the roots of a cypripedium that has been potted some months We have found that where seed has been sown on prepared surfaces and on freshly-potted plants, that in many cases it has taken a long time to germinate; and where polypodium or osmunda fibre has been used in the potting compost, the seed has rarely germinated under a year. It is advisable to use as far as possible at the present time such surfaces as may be available from among the plants that will not require repotting. Sow the seed thinly.

WINTER-FLOWERING CYPRIPEDIUMS.—Now that so many of the winter-flowering cypripediums have passed out of bloom, it is desirable to repot or divide those needing it, and prepare the surface so that it may be ready to receive the seed as occasions demand. In mixing the compost, see that it is porous and of a lasting nature, and to retard the overgrowth of sphagnum moss the heads may be picked off before the moss is finely chopped.

ODONTOGLOSSUM SEEDS will also be ripening now, and some portion should be immediately sown, the remainder being held over until the lighter days. These germinate best when sown around plants of their own kind, or closely allied genera. When sown around plants that were repotted last autumn all sphagnum that is likely to overgrow the seedlings should be removed. We find it difficult to secure germination, unless there is a portion of leaf-soil in the potting compost. We use nothing but peat, sphagnum, and broken leaves for our odontoglossums, so that we have generally little trouble in finding suitable seed beds. Care is necessary when watering to prevent the seeds being washed away. It is desirable to carefully dip the pots containing seeds, so that there may be no danger of the seeds being floated away. I am convinced that many failures may be traced to carelessness in watering.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

SCHIZANTHUSES. — The Wisetonensis and retusus varieties of these delightful annuals are indispensable for conservatory decoration during late spring and early summer. The plants which were raised in the autumn are growing on shelves in a cool greenhouse. Their chief requirements now will be timely attention to shifting into larger pots, staking, and careful watering. A compost of loam, leaf-soil, and sand, or lime rubble, will be suitable. The staking must be done efficiently, but neatly. Give plenty of fresh air when the weather is favourable, and use fire-heat sparingly.

MIGNONETTE.—The autumn-sown plants must be kept growing as near to the glass as possible in a cool greenhouse. These will be useful for their fragrance either in the conservatory or dwelling during the spring months. Some mild stimulants must be given the plants when they begin to develop their flower spikes. Another sowing may be made now.

CELSIA ARCTURUS. — This is a most useful pot plant for use in the conservatory. It must not be hurried by the use of fire heat, or the flower spikes will be weak. Plenty of stimulating manure when developing their flowers is needed.

CINERARIAS AND CALCEOLARIAS.—These should, if possible, be grown on a cool base, such as coal ashes or gravel; and, although they do best in a cool greenhouse, they must not be subjected to cold draughts. Give them plenty of feeding when their final pots are full of roots. They are very subject to attacks of aphis, and should be lightly fumigated occasionally to keep them clean.

CHRYSANTHEMUMS. — The cuttings which were inserted last month must be examined frequently, and those which have rooted must be placed on a shelf near the glass in a cool house. Do not expose them to cold draughts. Old stools which are being retained for stock must be kept near the glass in a cool house, and if they are producing too many cuttings, the most forward should be removed.

BULBS.—Any bulbs which are still buried in ashes must be examined, as the unusually mild weather will have encouraged them to grow freely. Move them to a cold frame until they are required for forcing.

LACHENALIAS.—These will need liquid manure and soot-water as the pots become filled with roots. Keep them growing near the glass in the cool greenhouse. They may be subjected to gentle forcing when the flower spikes appear, should it be desirable to hasten their flowering. — E. HARRISS, Lockinge Park Gardens.

HARDY FRUITS.

WALL TREES.—With the exception of peach and nectarine trees, we always commence and push forward as fast as possible with the pruning and nailing of all wall fruit trees as soon as the leaves have fallen in the autumn, beginning with those on the coldest aspects. If, however, through pressure of other work, these trees have so far been neglected, I would strongly urge that the work be taken in hand at once, and be proceeded with as quickly as possible, so that the branches, etc., may receive a thorough cleansing before the buds become too advanced.

MORELLO CHERRIES.—These bear the finest fruit on sturdy young growths, so that when attending to the trees during their growing season, suitable shoots should be retained to take the place of those which have borne fruits, and are not required for extension. It is not necessary to take down the whole of the trees if the main branches are equally balanced, but great care should be taken to see that none of the old ties or shreds are pinching the bark. Spur back to a couple of buds all weak shoots, and those not required for filling up bare spaces, and train all the shoots as straight as possible, so that, when finished, the trees present a good appearance. It takes no longer to train a tree well than it does to train it badly. Aim to keep the whole of the walls covered from the bottom to the top with clean, sturdy, fruiting wood. Young trees, if not equally balanced, will need to be taken from the walls and have their main shoots regularly placed and made secure before commencing to fill in the bare spaces with the young fruiting shoots, and those required to form an even-balanced head.

PLUMS.—When pruning and regulating the branches of plums, I strongly advise the retention of plenty of young wood. Although the plum fruits well on the spur system, I have always had the best crops produced from young two-year-old wood closely nailed to the walls, and in some seasons some capital fruits have been grown on the previous year's wood. Any old trees that yield only scanty crops, and that are really not worth the room and labour, should be grubbed out. Among our most dependable varieties at Wrotham are Early Transparent Gage, Oullin's Golden Gage, Washington, Jefferson, Denniston Superb, Coe's Golden Drop, Victoria, Monarch, Grand Duke, Gisborne, and Pershore. Thoroughly prepare the station for all young trees, and fill up with good loam, etc. In the case of narrow borders, first trench the whole two feet six inches deep, and then set out the stations for the reception of the trees, 17 or 18 feet apart.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

POTATOES.—Where new potatoes are required early in the season, the tubers should now be planted either in pots or heated pits. For pots the soil should be of a rich, open nature, and 10in. pots are a useful size for the purpose; half fill the pot with soil when planting, and add more soil when the growths are sufficiently advanced; that is, when they are showing above the pot level. An early peach house or vinery will afford the necessary conditions for starting the tubers. Water should be carefully given in the early stages of forcing. When making use of heated pits a mild hotbed materially assists and hastens early production; it is, of course, not a necessity where top heat is at command. The soil should be in good condition, and well warmed through previous to introducing the tubers. Light, sandy loam, with a liberal addition of well-rotted leaf-mould, spent mushroom bed manure, and wood ashes which have been well mixed, should be placed in the pit to a depth of nine or ten inches. Soil previously used for frames, and again pressed into service, will require the addition of a goodly portion of the above compost. Potatoes may also be forced in unheated pits, but in this case a good body of fermenting material is necessary to maintain a regular and continuous warmth, and adequate protection must be afforded during severe weather. This method entails a considerable amount of labour and watchfulness. The tubers should be well sprouted preparatory to planting, and further batches should be introduced into slight heat for planting in cold frames. Sharpe's Express is an excellent forcing variety.

SOWING SEEDS FOR EARLY CROPS.—A sowing should now be made in pots, pans, or boxes, according to requirements, of the small early maturing cabbages; Sutton's Earliest and Tender and True are early, and form a succession. Also lettuce of the Tom Thumb and Golden Ball class, and onions, celery, and leeks, if desired for exhibition purposes. As a succession to the December-raised tomatoes, which are usually fruited in pots, make a further sowing for pot culture or planting out. Towards the end of the month is quite early enough to sow the first batch of cucumbers, and one seed should be inserted in a 3in. pot, using fresh loam—free from eelworms and wireworms—with a liberal addition of leaf-mould and sand. It is a good plan to insert the seed upright in a pinch of sand, as I find this hastens germination, and the danger of the seeds rotting is thereby greatly reduced. The tomato and cucumber seeds should be placed in brisk heat, and covered up until germination takes place. A temperature from 50 to 55 deg. will suffice for the cabbage, lettuce, onions, etc., and these should be covered to exclude light until the young seedlings appear.—W. MESSENGER, Woolverstone Park Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

JANUARY 21.

The second exhibition held at the Royal Horticultural Hall this year was not up to the average, either in extent or interest. The hall seemed fairly well filled, but there were numerous exhibits of horticultural sundries, garden furniture, pottery, and paintings, and nothing was crowded. The outstanding exhibit was the very fine one of home-grown oranges from Sawbridgeworth. Orchids were fairly well represented, and perpetual carnations were largely shown. Cyclamen, apples, vegetables, and hardy flowers (chiefly alpines) were other features.

FLORAL COMMITTEE.

The exhibit of cyclamen from Messrs. Sutton and Sons, Reading, was a large and bright one, and the flowers were varied in size, shape, and colour. The big, bold blooms of Giant White contrasted finely with Giant Crimson and Vulcan, while among fringed forms a distinct improvement was noticed, the good form being retained in conjunction with delicate fringing and pretty colour combinations. In some of the plants the leaves are finely variegated and as handsome in their way as the flowers. The St. George's Nursery Company, Harlington, Middlesex, exhibited baskets of salmon-coloured cyclamen, but it was the beautiful silvery markings of the leaves of their variety St. George (A.M.) that attracted general attention and admiration.

A large collection of ferns was submitted by Messrs. H. B. May and Sons, Edmonton; small-growing polypodiums and nephrolepis were the chief kinds represented. Mr. L. R. Russell, Richmond, brought up a collection of ivies and some graceful plants of Jasminum pumilianum, carrying numbers of golden-yellow flowers. Some bright winter-flowering begonias of the semperflorens type were shown by Mr. W. A. Manda, St. Albans. Mr. Manda also showed a large vase of a new H.T. rose named Mrs. Charles Russell; this is a shapely, broad-petalled, deep reddish-rose variety, with paler shading. The flowers had been cut about fourteen days, and had travelled from the United States in cold storage, and, after such a journey, were of sufficient merit to secure an A.M. Zonal pelargoniums from Messrs. H. Cannell and Sons, Swanley, proved very interesting by reason of their brilliant colouring,, while the long-stemmed plants destined to form standard and half-standard specimens excited a good deal of comment.

Varieties of Azalea indica made a very bright display as staged by Messrs. Jas. Veitch and Sons, Chelsea; with these were some splendidly developed white and salmon cyclamens, the blue Coleus thyrsoideus, freesias, the rich blue Tillandsia Lindeni, etc. A fine group of forced flowering shrubs and early spring flowers from Messrs. Wm. Cutbush and Son, Highgate, was very noticeable, but the forced shrubs were only a part of the display, as the foreground was occupied by delightful groups of Iris Danfordæ, I. histrioides major, I. reticulata, and I. Krelagei, with many other good things.

Narcissus mini-cycla, a very charming and dainty hybrid between N. minimus and N. cyclamineus, the latter being the seed parent. The tiny flowers are perfect miniatures of golden trumpet daffodils, but the spread of the perianth segments is only 1½in. This was raised and shown by Mr. F. H. Chapman, Rotherside Gardens, Rye, and gained an A.M. We believe that January 21 is the earliest date on which a daffodil has ever gained an award.

Hardy rhododendrons from Messrs. R. Gill and Sons, Falmouth, were very attractive, especially the trusses of R. arboreum, R. cornubia, R. argenteum, and R. barbatum. Primula Winteri was largely represented. As usual, Mr. G. Reuthe, Keston, contributed many interesting hardy plants, and among these we made note of the exquisite species of crocus, Berberis nepalensis, irises of the reticulata group, Erica carnea, Oriental hellebores, Garrya elliptica, and hardy cyclamen.

The rock garden arranged by Messrs. John Piper and Sons, Bayswater and Barnes, contained a good selection of dwarf shrubs and little groups of Sisyrinchium grandiflorum, S. g. album, Saxifraga Boydi alba, Hepatica triloba plena, P. Winteri, and P. denticulata. From the Wargrave Plant Farm, Twyford, Berks, came Cyclamen ibericum, Arabis rosea, Iris histrioides, Soldanella alpina, Artemesia frigida, and other very interesting alpines.

Iris fimbriata, Viola gracilis, P. malacoides, P. Isabellina, P. denticulata alba, and P. Cashmeriana were a few of the early alpine flowers displayed in a fairly large group by Messrs. T. S. Ware, Lim., Feltham, Middlesex. Mr. James Box, Lindfield, Sussex, showed hardy heaths, colonies of coloured primroses, Primula Cashmeriana, and P. malacoides, with a few sedums, saxifrages, etc.

Alpine flowers came from Mr. C. Elliott, Six Hills, Stevenage, and among these the colonies of Saxifraga Bursariana and Morisia hypogæa were very pretty. Messrs. Barr and Sons, Covent Garden, presented a few early daffodils, a charming series of crocuses, primulas, saxifragas, snowdrops, anemones, and a very beautiful lot of Cyclamen ibericum, showing a goodly range of colouring in the seedling forms exhibited. The golden crocus chrysanthus var. E. A. Bowles was particularly handsome in this group. The brightly-coloured primroses shown in some quantity by Messrs. G. and A. Clark, Dover, foretold the coming of spring, and with these were Iris stylosa, I. s. alba, crocuses, and hardy cyclamen.

Mr. T. Smith, The Gardens, Coombe Court, Kingston Hill, provided a very bright little exhibit of forced Pyrus Schiedeckeri, Prunus triloba, these forming a background to muscaris, lachenalias, Anemone blanda, Chionodoxa Lucilæ, Iris reticulata, I. histrioides, and a good strain of Primula obconica. Very pretty were Iris reticulata, I. r. Krelagei, Crocus Sasianus, C. aureus, C. biflorus, Rhododendron præcox, and Erica carnea, exhibited by Messrs. R. Wallace and Co., Colchester.

Messrs. Whitelegge and Page showed various alpines in pots and pans, chiefly irises, saxifragas, and primulas, the latter genus being freely represented by P. malacoides. Mr. Maurice Prichard, Christchurch, Hants, had a very fine lot of Primula denticulata and its variety alba, of Gentiana acaulis, Erica mediterranea hybrida, and a goodly number of varieties of Helleborus orientalis, including the lovely purple-spotted Grosse Claude.

The great popularity of perpetual carnations was once more demonstrated by numerous exhibitors. Mr. H. Burnett, Guernsey, had a very bright display of fine flowers of Mandarin, Empire Day, R. F. Felton, Mikado, Marmion, C. F. Raphael, White Wonder, Mrs. Tatton, and Lady Alington. Messrs. Stuart Low and Co., Enfield, were fairly large exhibitors of carnations, and Fairmount, Cinnabar, Baroness de Brienen, Lady Northcliffe, and British Triumph were the outstanding varieties; this firm also displayed some excellent cyclamen.

A very fine vase of the scarlet sweetly-scented Mrs. L. Mackinnon formed a splendid centrepiece in a group of perpetual carnations shown by Messrs. Wm. Cutbush and Son, Highgate; the flowers were of grand size and substance; R. F. Felton, Goldfinch, Edna, Countess of Latham, and Mrs. Waldorf Astor were a few other striking varieties in a goodly group. Messrs. W. Wells and Sons, Merstham, were also represented by carnations, and their leading varieties were St. Nicholas, Salmon Enchantress, Benora, Gloriosa, Northport, and Geisha.

Messrs. Allwood Bros., Haywards Heath, were well represented by their good variety Mary Allwood, by La Rayonante, Fairmount, Scarlet Glow, Rosette, and Wivelsfield Wonder. Mr. C. Engelmann, Saffron Walden, had a good exhibit, and the bunches and stands of Lady Northcliffe, Sunstar, Harlequin, Elektra, White Perfection, Salome, and the red-striped Fanny were especially attractive.

Mr. R. Hughes, Ellesmere, Potters Bar; and Miss E. S. Ough, Streatham Common, exhibited paintings of flowers and garden scenes.

ORCHID COMMITTEE.

Messrs. Sander and Sons, St. Albans, presented a very bright collection of orchids, and used ferns and moss pleasingly among and below the flowers. Cypripedium insigne Louis Sander was an exceptionally big bloom, obtained by crossing the Harefield Hall and MacNabiana varieties of the popular C. insigne; Odontioda Bradshawiæ, Pleurothallis Roezli with its blackish flowers, Oncidium splendens, Dendrobium Brymerianum with its beautifully-fringed golden blooms, Saccolabium Harrisonianum, and S. bellinum superbum were other good things on view.

In the group from Messrs. Stuart Low and Co., Bush Hill Park, Enfield, Cattleya Luminosa, C. Harrisonæ, Oncidium splendidum, and freely-flowered specimens of the showy dendrobium Wardianum were the chief features.

A graceful exhibit from Messrs. Charlesworth and Co., Haywards Heath, consisted largely of fine spikes of odontoglossums, odontiodas, and varieties of Lælia anceps. A few things of special note were Odontoglossum armainvilliersense, O. ardentissimum, O. Wilckeanum, O. Lawrencianum, the quaint Catasetum discolor, Zygopetalum Roeblingianum, and the bright Odontioda Keighleyensis with a pair of freely-branching spikes of crimson-scarlet flowers. Mr. W. A. Manda, St. Albans, exhibited numerous varieties of Cattleya labiata, and a few cypripediums and philcenopsis, and associated these with the very handsome Polypodium Mandaianum.

Mr. J. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate, showed a fine plant of Cymbidium Lady Colman with six spikes of bloom, a large specimen of Cirrhopetalum robustum, and also a large one of the pretty Restrepia striata, with Zygocolax Veitchi and Z.-c. Wiganiæ Masdevallia elephanticeps, Pleurothallis scapha, and Masdevallia tovarensis. From Westonbirt, Mr. H. Alexander, grower to Sir G. Holford, brought up the fine Cypripedium Jura, a descendant from C. insigne Mostyn. M. Firmin Lambeau sent over from Brussels the lovely red, crimson, and yellow Lælio-cattleya Firmini var. Ardens (A.M.), and the no less beautiful cattleya Enid var. Firmin Lambeau (F.C.C.), obtained by crossing C. Mossiæ Reineckiana and C. gigas Frau Melanie Beyrodt. Francis Wellesley, Esq. (gardener, Mr. Hopkins), submitted Cypripedium Cupid magnificum and the chaste Brasso-cattleya Wellesleyæ, Brassavola glauca and C. Mossiæ Wagneri.

Mr. Shill, gardener to Baron Bruno Schroder, Egham, showed a three-spiked specimen of the lovely Lælia anceps Hilliana, which has a delicate rose-pink lip. Messrs. Hassall and Co., Southgate, put up good forms of Odontoglossum Lambeauianum, O. amabile, and O. percultum, and a good plant of Cattleya Blacki. Mr. E. H. Davidson, Orchid Dene, Twyford, brought forward Sophro-cattleya Saxa Orchid Dene var. (A.M.), with a broad, deep rosy-red flower; Odontioda Bradshawiæ, and Odontoglossum illustrusissimum.

From Cheltenham, Messrs. J. Cypher and Sons, brought up Calanthe Bryan, C. bella, C. William Murray, and Lælia anceps Hilli, their long, arching spikes curving over Lycaste Balliæ, Miltonia Hyeana, Cypripedium Beckmani, C. aureum viginale, C. Vandyke, C. Venus, and the very pretty white and yellow Cœlogyne intermedia (A.M.), a cross

between C. cristata Lemoinana, and C. Massangeana.

Mr. G. Day, gardener to H. S. Goodson, Esq., Fairlawn, Putney, showed Odontoglossum Aireworthy Goodson's var. (A.M.), handsomely spotted with rich crown on a blush ground, and somewhat in the way of O. Jasper.

Odontoglossum Phoebe was well shown by Mr. H. A. Tracy, Twickenham, and Mr. Metcalfe, gardener to Lady Wernher, Luton Hoo, Luton, showed a group of finely-grown plants of Calanthe Regnieri and C. Baron Schroder albescens, carrying spikes 4ft. long. Mr. C. J. Phillips (gardener, Mr. R. J. Bucknall), The Glebe, Sevenoaks, submitted Odontioda Madeline var. Prince of Orange (A.M.) (Odontioda Charlesworthi × Odontoglossum crispum), a very distinct pale yellow-ground flower, with light yellow-brown blotches, edged with deep yellow; the lip is yellow, with a central red-brown blotch and a yellow crest; from the same exhibitor came Odontioda Joan, with crimson and purple flowers.

FRUIT AND VEGETABLE COMMITTEE.

One of the largest and most striking exhibits in the show was from Messrs. Thos. Rivers and Son, Sawbridgeworth, and consisted wholly of fine home-grown oranges. There were large numbers of picked fruits, scores of heavily fruited cut branches, showing how free-cropping many of the varieties are, and a number of fruiting trees in pots and tubs. In the centre of the group fruiting branches were tied to wires overhead to show how the plants fruit in a span-roofed house. Varieties of special merit were Seville, Silver Achilles, Navel, St. Michael's, Jaffa, and Long Orange, while the citrons, lemons, and the tiny myrtle-leaved oranges were fully as attractive as the quantities of brilliant and richly-flavoured oranges.

A very bright and interesting collection of apples from Messrs. J. Cheal and Sons, Crawley, attracted a great deal of attention, and very tempting were the dishes and baskets of Paroquet, Wealthy, Cox's Orange Pippin, Encore (fine), Rival, Newton Wonder, Crawley Beauty (exceptionally brilliant), King of the Pippins, Ribston Pippin, Allington Pippin, Beauty of Stoke, etc., etc. Fine specimens of intermediate carrots, Sutton's Black and Blood Red beets, Ailsa Craig and Globe onions, and Supreme and Centenary potatoes were capitally shown in a collection of vegetable roots by Messrs. Sutton and Sons, Reading.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Cattleya Enid var. Firmin Lambeau, from Mons. Firmin Lambeau, Brussels.

Award of Merit.—To Cattleya Firmin Lambeau var. Ardens, from M. Firmin Lambeau, Brussels; to Cœlogyne intermedia, from Messrs. J. Cypher and Sons, Cheltenham; to Odontioda Madeline var. Prince of Orange, from Mr. C. J. Phillips, The Glebe, Sevenoaks; to Sophro-cattleya Orchid Dene var., from Mr. E. H. Davidson, Orchid Dene, Twyford, Berks; to Odontoglossum Aireworth Goodson's var., from H. S. Goodson, Esq. (gardener, Mr. G. Day), Fairlawn, Putney; to Rose Mrs. Charles Russell, from Mr. W. A. Manda, St. Albans; to Cyclamen St. George, from the St. George's Nursery Company, Harlington; and to Narcissus mini-cycla, from Mr. F. H. Chapman, Rotherside Gardens, Rye.

MEDALS.

Gold.—To Messrs. T. Rivers and Son, Sawbridgeworth, for home-grown oranges.

Silver-gilt Knightian.—To Messrs. J. Cheal and Sons, Crawley, for apples and pears.

Silver Flora.—To Messrs. Charlesworth and Co., Hayward's Heath, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Mr. Metcalfe, gardener to Lady Wernher, Luton Hoo, Luton, for calanthes; to Mr. H. Burnett, Guernsey, for carnations; to Messrs. Wm. Cutbush and Son, Highgate, for forced flowers, carnations, etc.; to Mr. Maurice Prichard, Christchurch, for hardy flowers; to Mr. L. R. Russell, Richmond, for shrubs; to Messrs. Sutton and Sons, Reading, for cyclamens; to Messrs. Jas. Veitch and Sons, Chelsea, for greenhouse-flowering plants; and to Messrs. H. B. May and Sons, Edmonton, for ferns.

Silver Banksian.—To Mr. W. A. Manda, St. Albans, for orchids; to Messrs. Hassell and Co., Southgate, for orchids; to Mr. C. Elliott, Stevenage, for rock plants; to Messrs S. Low and Co., Enfield, for carnations; to Mr. G. Renthe, Keston, for hardy plants; to Mr. T. Smith, The Gardens, Coombe Court, Kingston Hill, for hardy flowers; to Messrs. R. Wallace and Co., Colchester, for hardy flowers; to Messrs. T. S. Ware, Lim., Feltham, for alpines; to the Wargrave Hardy Plant Farm, Lim., Wargrave, for hardy plants; to Messrs. Gill and Sons, Falmouth, for rhododendrons, etc.; and to Messrs. Sutton and Sons, Reading, for vegetables.

Bronze Banksian.—To Messrs. G. and A. Clark, Dover, for hardy flowers; to Messrs. J. Piper and Co., Barnes, for alpines.

SCIENTIFIC COMMITTEE.—January 7.

Present: Mr. E. A. Bowles, M.A., F.E.S., F.L.S. (in the chair); Messrs. J. O'Brien, G. Wilson, R. H. Pearson, E. M. Holmes, W. Hales, A. Worsley, and F. J. Chittenden (hon. secretary).

ADIODA × ST. FUSCIEN. — Messrs. Charlesworth and Co., of Haywards Heath, sent a hybrid between Ada aurantiaca and Cochlioda Noezliana with narrow-petalled flowers of a deep red colour on a many-flowered raceme. This cross was first shown at the International Exhibition at Chelsea by M. Graire, and had also been raised by Messrs. Charlesworth simultaneously. The committee unanimously recommended that Certificates of Appreciation should be awarded to both M. Graire and to Messrs. Charlesworth for their work in raising this unique cross.

CYNOCHES COOPERI.—Messrs. Sanders showed a plant under this name which was thought by some to be identical with C. pentadactylon, but Mr. Rolfe reports that, though very similar in structure to that species, it is quite different in colour, the sepals and petals being of a nearly uniform mahogany-brown, and there are also some differences in the details of the lip. It would therefore appear to be sufficiently distinct to warrant a new name, and the Award of Merit recommended, subject to the name being found correct, therefore stands.

EPIDENDRUM CILIARE × LÆLIA CINNABARINA.—Mr. J. O'Brien showed flowers of a hybrid between these two plants, pointing out that, though not very conspicuous, the markings on the lip followed the remarkable fringing of the Epidendrum parent, and the form of the lip was markedly elongated.

MILTONIA VEXILLARIA × ODONTOGLOSSUM CRISPUM.—At the corresponding meeting last year M. Firmin Lambeau showed a seedling of this cross, and the committee requested that further plants of the same raising should be shown when the opportunity occurred. M. Lambeau now sent two more plants, bearing flowers very similar in appearance, and leaving no doubt that the parentage was as stated originally.

DATURA ARBOREA. — Mr. Holmes showed a flower of D. arborea bearing a white out-growth from the outside of the corolla similar to those frequent in gloxinias and several other plants. This species not infrequently produced them.

INSECT ATTACKING FENNEL. — Mr. Holmes also showed a number of insects belonging to the genus Typhlocyba (leaf-hoppers). Few insects attack the fennel, possibly owing to the oil it contains, but these seemed remarkably numerous.

GROUSE EATING WILLOW BUDS. — Mr. F. M. Ogilvie, of the Shrubbery, Oxford, sent shoots of a willow on which he had seen grouse feeding in Argyllshire. The crop of the grouse was full of the buds. The willow appeared to be Salix repens, an apparently uncommon food plant for grouse in Britain.

CYCLAMEN WITH BRANCHING INFLORESCENCE.—Mr. Hawkes, of Osterley Park Gardens, sent shoots of cyclamen bearing leaves springing from the peduncles, and in their axils other flowers. These branching peduncles of cyclamen appear not uncommon in collections where the plants are growing with unusual vigour.

GALL ON ROOT OF THUYA.—A large globular growth the size of a cricket ball was shown on the root of a Thuya. It was very similar in appearance and structure to those not uncommon on the roots of loganberries and other plants, and was possibly allied to the crown-gall which attacks so many widely-different plants.

National Chrysanthemum Society.

A largely-attended meeting of the executive committee was held at Carr's Restaurant, Strand, W.C., on Monday, January 20, and a great deal of business was got through in excellent order and despatch. The draft balance-sheet and report of the committee were duly considered and passed for presentation to the annual meeting, and it was a pleasure to learn that the society has now a reserve fund of £75, and carries forward a small balance to the good as well. The work of the Floral Committee occupies considerable space in the report, and shows that the society is keeping abreast of the times.

The schedule sub-committee's reports were considered and adopted, and arrangements were made for the annual meeting on February 17, and a conference in December next, while the question of the annual outing was discussed at some length.

A somewhat unusual proceeding was the hearty passing of a vote of thanks to the sub-committees and officers who had so carefully prepared the business of the evening that the sitting was not unduly prolonged.

United Horticultural Benefit and Provident Society.

The monthly meeting of the committee of this society was held at the Royal Horticultural Hall on Monday, January 13. Mr. Chas. H. Curtis in the chair. Five new members were elected. The sick pay for the month amounted to £79 6s. 6d. Two members over 60 years of age were allowed to withdraw double the amount of their interest, being £2 11s. 4d. and £3 12s. 10d. respectively. One lapsed member, having reached the age of 60, was allowed to withdraw his deposit account, amounting to £24 14s. 2d. Also one member having reached the age of 70 years, having the handsome sum of £161 7s. 7d. standing to his credit, was granted leave to withdraw £61 7s. 7d., leaving £100 still standing to his credit. The committee wishes to draw the attention of young gardeners to these figures, which should be a great inducement for them to fill up their forms and thus become members of the society.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the PUBLISHING MANAGER, 148-9, Aldersgate Street, London, E.C., who will give the matter immediate attention.

East Anglian Horticultural Club.

The twenty-third annual dinner of this club was held at the Criterion Restaurant, Norwich, on the 15th inst. The committee had tastefully decorated the tables with pot plants and cut flowers from the members. Mr. F. Williams presided, and was supported by a large and influential body of local amateur and professional gardeners. After the loyal toasts had been duly honoured, Mr. J. E. T. Pollard gave "Success to the East Anglian Horticultural Club." He congratulated the club upon its splendid membership and its strong financial position, also upon the useful educational work it had done. He thought the club ought to have a motto, such a one as "Advance horticulture," or "Progress," for both these had been well maintained.

The President, the Vice-president (Mr. J. Clayton), and the Secretary (Mr. W. L. Wallis) fittingly replied to this toast, each remarking upon the splendid brotherly feeling that existed among the members, and which, no doubt, helped it to maintain its present unique position. Mr. J. Forder ably proposed "The Norfolk and Norwich Horticultural Society," one of the oldest in the country, it having been in existence for 83 years. To this toast Mr. C. E. Pilling, the hon. secretary, responded, and gave a much brighter outlook of affairs than one has heard for the past year or so.

Mr. A. G. Stark, of sweet pea fame, gave "Success to the Royal Horticultural Society," remarking, among other things, that it was the mother of all British horticultural societies, and, in fact, was recognised as the leading society throughout the world. Mr. C. Daniels replied, and gave a resume of the useful work being carried on at Wisley.

"The Horticultural Trade of Norfolk" was proposed by Mr. H. Perry, who said that by "trade," the name of any place was carried far beyond the confines of its own little sphere of labour, and he knew that the name and fame of Norwich and Norfolk had gone far and wide as the result of the enterprise of the leading firms associated with horticulture, whose activities were carried on within the county. Other toasts were "The Visitors," "The Press," and "The Prize Donors." A good musical programme was also provided.

Scottish Horticultural Association.

The annual business meeting of the above association was held in Dowell's Rooms, George Street, Edinburgh, on January 14. Mr. Massie, the president, was in the chair, and there was an attendance of 170 members.

The annual report stated that the work of the past session had been carried on vigorously, and that the average attendance at the ordinary monthly meetings was over 90. The exhibits at the monthly meetings were generally of much excellence, and four First Class Certificates, 14 Certificates of Merit, and eight Cultural Certificates were awarded to new or meritorious plants, etc. Chiefly as the result of a personal appeal by Captain Stirling of Keir, the honorary president, there had been a large accession of new members in the higher grades of the scale of subscriptions brought into existence last year under the new constitution, and the membership now stood at about 1,400, a net increase of 120 over the previous year's number. The Horticultural Institution Fund, which, at the commencement of the previous year stood at £80, now amounted to £288; a benevolent fund had been instituted, and the funds of the association, which now, after providing for present depreciation of stocks, stood at £828, were fully £100 better than at the beginning of last year. A considerable number of local secretaries had been appointed in the various Scottish counties, and the governors of the Edinburgh and East of Scotland College of Agriculture had favourably entertained a suggestion made by the Council that horticulture should have direct representation on the governing body of that institution. The chrysanthemum show, owing to the sunless, backward season, was rather smaller than usual; nevertheless, there was a balance of income over expenditure of £22 18s. 9d., and it was visited by over 21,000 people during the three days. Both the Council's report and the financial statement were adopted unanimously.

On the motion of Mr. Fife, seconded by Mr. Whytock, the president, Mr. Massie, was elected an honorary life member of the association.

Captain Stirling of Keir was re-elected honorary president for the current session. Mr. David King was elected president, and Messrs. R. Fife and W. Galloway were elected to the two vacancies in the vice-presidencies. The following were elected to the seven vacancies in the Council, viz., Messrs. W. Copeland, Dr. W. G. Smith, H. Thomson, G. Cochran, A. Johnstone, W. Mather, and A. C. Scott. Mr. A. D. Richardson was re-elected secretary and treasurer, and Messrs. Robertson and Carphin, C.A., were elected as official auditors. On the motion of Mr. King, a hearty vote of thanks was accorded to the retiring office-bearers, which was acknowledged by Mr. Massie.

A donation of £10 each was voted to the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund.

It was intimated that, on the invitation of Mr. C. W. Cowan, the members would visit Dalhousie Castle on April 19. A syllabus of subjects for session 1913 was submitted, and it was agreed to revert to the former hour of meeting, viz., 7.30 p.m., all the year round. A number of donations to the library, including 25 volumes of the "Gardeners' Chronicle," from 1841 onwards from Messrs. Wm. Thomson and Sons, Clovenfords, were intimated.

The new president, Mr. King, will deliver his inaugural address at the meeting on February 4.

Morley Paxton Society.

This society held its annual meeting on January 3, the President (Mr. E. Bentley) presiding over a large attendance. The report showed that the work of the society had been very successful, both horticulturally and financially, there being many signs of a healthy growth of interest in horticulture in the district. The eighth annual chrysanthemum show, held in the Town Hall in November last, was a record in many ways, the blooms were of a high order, and the attendance large.

The secretary, Mr. S. J. Wormald, Zion House, Morley, received instructions to make enquiries as to the methods followed in holding cottage garden competitions, with a view to establishing them in Morley. If any ings for the two shows representing an in- this direction, Mr. Wormald will be pleased if they will communicate with him.

Reading Gardeners' Association.

The annual meeting of the Reading and District Gardeners' Mutual Improvement Association was held in the Abbey Hall, Reading, on Monday evening, when there was a large attendance of members. The chair was occupied by the President, Mr. F. B. Parfitt, and he was supported by Mr. Leonard Sutton (vice-president), Mr. L. Castle (hon. secretary), Mr. F. W. Macdonald (hon. treasurer), Mr. F. W. Drew (chairman of the committee), Mr. Blackwell (Fox Hill), and others.

The annual report, which was presented by the Hon. Secretary, stated that the year had been very successful. The year ended with a membership of 291. In conclusion, the report stated that if the society was to maintain its high standard the wholehearted support of every member must be given.

The balance-sheet was presented by the Hon Treasurer, and showed that the year started with a balance in hand of £50 11s., and, after meeting all liabilities, the year ended with an increased balance of £59 13s. 9d.

The President, in moving the adoption of the report and balance-sheet, paid a tribute to the many kindnesses the Association had received at the hands of the vice-president.

The Vice-President seconded, and the proposition was agreed to.

The Hon. Secretary and the other officers were heartily thanked for their services to the Association. Mr. Castle and Mr. Drew acknowledged the compliment.

The president, vice-president, secretary, treasurer, chairman of committee, and other officials were re-elected, and a committee was appointed for the current year.

OBITUARY.

MR. EDWARD WEBB, J.P.

It is with much regret that we record the death of Mr. Edward Webb, J.P., D.L., the senior partner in the firm of Messrs. E. Webb and Sons, of Wordsley, which occurred at Paris on the 21st inst. Mr. Webb was on his way to Nice for a rest and change of air, and was seized with paralysis during his journey from Calais to Paris. He was taken to a nursing home in Paris, where, in a short time, he passed away. From the time of entering the firm, when comparatively young, until the close of his long life, Mr Webb took a very active part in the management of the great firm of which he was head, and enjoyed a high reputation amongst those with whom he had business relations, and was highly respected by the firm's employees at Wordsley and elsewhere.

NEWS FROM HEADQUARTERS.

VEGETABLES FOR EXHIBITION.

It is still very early in the new year, but if you are to be in front of your neighbours when exhibition time comes round, it is time a few of those subjects which require a long growing season to bring them to perfection were sown. Even if you do not aspire to exhibit, it is very gratifying to have a few dishes of choice vegetables earlier in the season than your friends.

A sowing of Leek seed should be made in gentle heat this month, when the resultant specimens will be available in good season either for gracing the exhibition table, or taking their place as one of the principal constituents of that delicious production of the land beyond Cock a Leekie. A variety which can be depended upon for producing fine show specimens is Carter's Holborn Model; whilst their improved Musselburgh is splendid for main crop.

Fine specimen onions will not materialise unless seed of a pedigree strain is sown under glass during the next week or so.

Carter's re-selected Ailsa Craig can be sown with every confidence, and was more successful than ever as an exhibition variety last season.

A sowing of Carter's Seville Giant Longpod Bean should also be made in a protected situation, as the young pods from early-sown plants will supply a few pickings of beans early in the late Spring or early Summer. Full particulars will be found in our Catalogue, which will be gladly sent.

JAMES CARTER & CO.,

Seedsmen to His Majesty the King,

RAYNES PARK, LONDON, S.W.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149 Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

BOXES FOR SWEET PEAS.—G. B., Colwyn: Can you give me information as to where I can obtain a box for the purpose of conveying sweet peas to exhibitions?—You could make a box for sweet peas if you are at all handy with carpenter's tools. It should be stout, have some ventilation holes, and be deep enough for three or four rows of bunches. In the case of a very deep box, if there are no shelves or carriers, there is a danger lest the lower rows of bunches become badly crushed by the weight of those above. If the flowers are to be conveyed in water, then the box must be deep enough to carry the flowers upright, and the inside measure should be about twenty or twenty-four inches. To the bottom of the box a number of stout tin tubes must be fixed by means of screws passing through a basal flange; these tubes should be from four to six inches apart, and when they are filled with flowers the blooms should be fairly close together, so that they cannot move much during the journey. A plug of moss or cotton wool should be placed in the mouth of each tube as soon as the flowers have been inserted, to keep the water from splashing up on the flowers. Have the box made with a strongly-hinged lid, and with the front of the box also hinged, because the flowers can be much more easily removed from the front than from the top. Any of the horticultural sundriesmen who advertise in our columns would make such a box for you.

SHADING FOR SWEET PEAS. — G. B., Colwyn: Will you please tell me what, in your opinion, is the best shading for sweet peas?—Not all sweet peas require shading, but, for exhibition purposes, the salmon, orange, and blue varieties should be shaded from the brightest sunshine. Butter muslin is capital material for shading sweet peas because the flowers do not need heavy shading; it is possible that by the seaside, in the height of summer, a double thickness might be desirable.

LÆLIO-CATTLEYA WALTER GOTT.—F., Kew: In a recent issue you make reference to Lælio-cattleya Walter Gott; am I to take this as correct, or is it a misprint for L.-c. Walter Scott?—Lælio-cattleya Walter Gott is quite correct, and the name is that of one of Messrs. Sander and Sons' employés. The hybrid was obtained by crossing Cattleya bicolor with Lælio-cattleya Bletchleyensis.

AFTER PASSING THE R.H.S. EXAMINATION.—G., Durham: Would you kindly tell me, through the columns of the GARDENERS' MAGAZINE, what is the best thing to be done after securing a First Class Certificate at the Royal Horticultural Society's examination for gardeners, to aid one in obtaining a good position? So much has been said and written of late regarding a gardener's education, diplomas, certificates, etc., that I am anxious to know what course to follow after winning a certificate. Some of us who do our best in this matter of education live so far from towns and from each other, that we rely upon the "G. M." to keep us in touch with present progress, therefore I seek your advice.—Given equal practical ability in gardening matters, a man who holds a First Class Certificate from the Royal Horticultural Society should have a distinct advantage over the man who has not passed the examination. It is most unfortunate that all too many who hold certificates seem to think that winning such award ends their personal effort towards success, and that thereafter they should not be called upon to soil their hands. Having won a certificate, and possessing practical ability that comes from personal experience in several gardens or nurseries, the next step will depend largely upon the end in view. Private gardening, public gardening, and horticultural teaching in connection with colleges, County Councils etc., have their allocations, and the nursery and market garden trades may offer inducements to those with business instincts. It is a great thing to be able to decide as early as possible which particular line of work is to be followed. Assuming you prefer private gardening, then proceed to widen your experience by securing service in first-class gardens in different parts of the country. In whatever subject you feel you are weakest, seek to improve yourself. Land surveying, drawing up plans for laying out new or improving old gardens, land measurement, and the cost of moving soil, etc., keeping accounts for presentation to steward or owner, and the science of manuring, are all important matters, especially in the management of the larger gardening establishments, and a knowledge of these things will prove valuable. Take advantage of local horticultural improvement societies, and cultivate a ready utterance. Cultivate also the art of letter-writing, and do not be afraid of writing to the heads of large and important gardens, if you wish to take service under them; everybody appreciates a legible, well-written and interesting letter. A well-written letter often secures an appointment, but only ability can keep the position obtained; the pity of it is that so many very capable men do not "get on" because their ordinary education has been so sadly neglected, and they are not able to turn their practical knowledge to the best account. Write us again; we shall be glad to hear from you, and to help you so far as it lies in our power to do so.

NATIONAL DAHLIA SOCIETY.—S. L. E., St. Neots.—Looking at the schedule of the National Dahlia Society for 1912, I cannot find any trace of the origin of the Society, of how many annual exhibitions the Society has held, or when it held its first exhibition. These matters are of interest, and if you can enlighten me I shall be glad. —The National Dahlia Society was instituted very many years ago, but the exact date escapes us for the moment. There were dahlia shows long before the N.D.S. was formed, and we have before us a four-page quarto schedule of an exhibition held in 1858. The title reads, "The First Grand National Dahlia Show, open to all exhibitors, will be held in St. James' Hall, London, on Thursday and Friday, the 23rd and 24th September, 1858." Prizes amounting to one hundred guineas were offered, and there were eleven classes. Eight of those classes were for show and fancy dahlias, one for a group of cut dahlias artistically arranged, one for the best device of dahlia blooms, and one for the best six dahlias in pots. It will be gathered from this that there were only the large double show flowers in those days, and that the numerous floral sections we now have, such as single, cactus, and pompone, did not exist then, while pæony-flowered and collarette types are of quite recent origin.

NAMES OF PLANTS.

R. J. A., Guildford.—1, Quercus ilex variegata; 2, Empetrum nigrum.

G. H. G., Exeter.—1, Iris stylosa; 2, Rubus leucostachys; 3, Ruta graveolens.

J. C., Cardiff.—1, Acacia dealbata; 2, A. Baileyana; 3, Jacobinea chrysostephana; 4, Nertera depressa.

E. C., Wrexham.—1, Garrya elliptica; 2, Calanthe Veitchi; 3, Episcia fulgida; 4, Monochætum Lemoinianum.

L. C. S., Frant.—1, Myrtus Ugni; 2, Pittosporum Tobira; 3, Euonymus japonicus radicans; 4, Diplacus (or Mimulus) glutinosus; 5, Desfontainea spinosa; 6, Juniperus Sabina.

Syringes

Every gardener knows that the very best Syringes the world has ever seen, or can ever hope to see, are the "FOUR OAKS," which are the only Syringes ever awarded a Gold Medal.

The Gardeners' Ideal Syringe is No.1 Four Oaks Undentable, 1½ × 20in. 21/-; or with Angle Joint 27/- For Spraying.—No 9 Undentable Syringe, 1½ × 20 in. 12/6 or with Angle Joint, 18/-

Any "Four Oaks" Syringes willingly sent on approval to Head Gardeners

Complete Catalogues of Spraying and Limewashing Machines and Syringes of every description free on application to the Sole Manufacturers:— The FOUR OAKS SPRAYING MACHINE Co., No. 30, Sutton Coldfield.

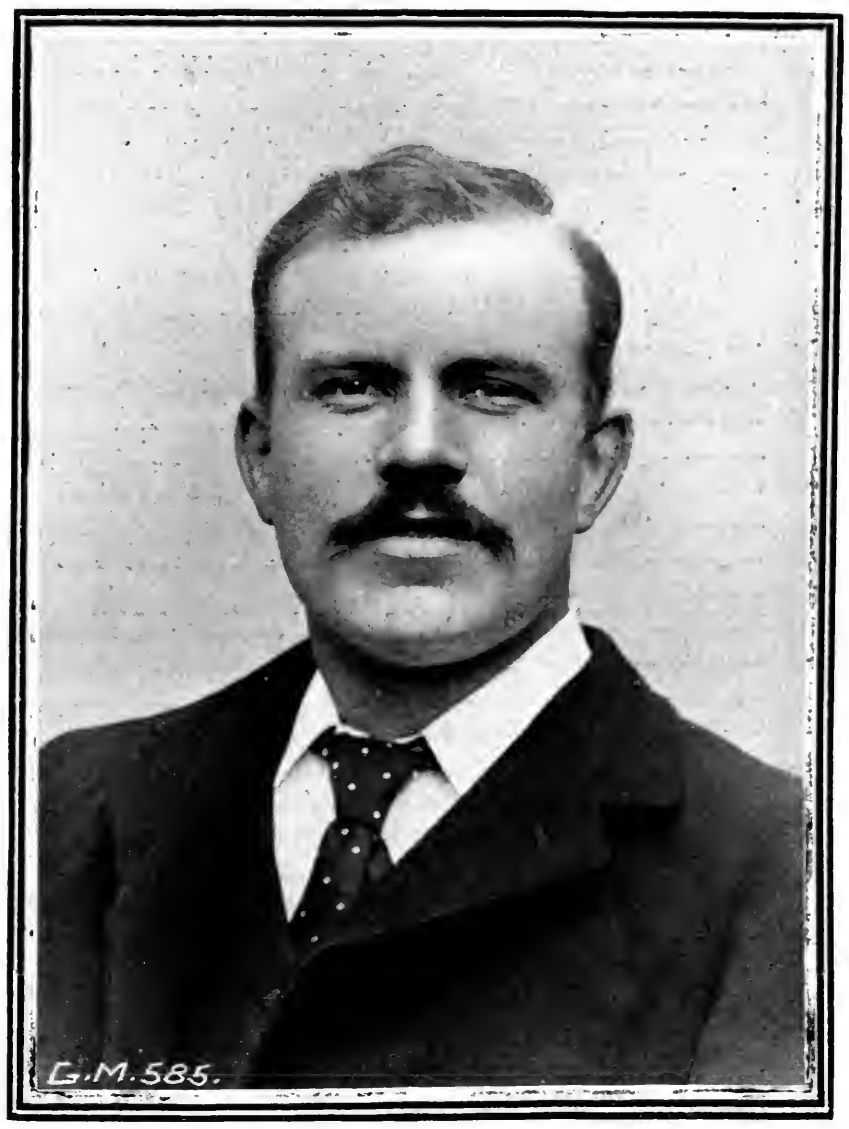
VOL. LVI.—No. 3,092. SATURDAY, FEBRUARY 1, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Wardian Case.

Under judicious management the Wardian Case may be rendered one of the prettiest and most interesting ornaments for room decoration, though far too rarely used for that purpose. The standard form consists of a shallow, oblong metal receptacle or open box, about thirty inches long by eighteen wide and five or six inches deep. This is intended to contain the soil. Over this and resting upon its edges, flanged for that purpose, is an oblong glass case, about two feet high at the sides, and with a domed or semi-cylindrical glass roof, with a long, narrow opening at the top, which is provided with a glass slip or slips to close it if desired. Each of the square ends are doors, thus permitting of easy access to the contents. The box aforesaid should be provided with a short pipe and tap at one end to admit of drainage, and it is well if the inside be well protected with tar, as the zinc, of which it is constructed, is apt to oxydize in time, and oxide of zinc is very poisonous to plant life, apart from the question of longer preservation. The outside should be well painted with some quiet colour, dark green for preference. Such a case affords precisely the the close, almost air-tight, conditions most congenial for the cultivation of delicate small-growing ferns like the Filmy Ferns, or for the accommodation of spore cultures in their juvenile state. To start such a case, as stagnant water and a waterlogged soil are very detrimental, even to such moisture-loving plants as ferns, the bottom of the box should first be well covered with broken pieces of flower pots hollow sides downwards; the outlet to the tap being particularly well guarded in this way. A layer of moss or very fibry material should entirely cover this to prevent the soil from clogging, and then over this sufficient open, sandy, fibrous, peaty fern compost can be placed, so that the box is quite full and well heaped up in the centre, as it is sure to settle down very considerably when watered. Upon this a small rockery of porous sandstone or broken brick, red for preference, can be arranged, in the interstices of which the ferns can be planted. A station may be made in the centre if desired for a small Todea superba, and the small-growing Hymenophyllums, tunbridgense, and unilaterale may be well bedded in smaller stations between the "rocks" together with a few plants of Trichomanes radicans. These latter in time will take hold and spread without interfering with the larger central Todea for a long time to come, while each season will add to their beauty as they develop. Practically this is quite enough to fill the case. To plant the smaller ferns which have creeping rootstocks, they should be pegged down upon the surface, and then buried shallowly by a mulching of extra sandy compost. This done, the compost is washed in by a douche of water from the spout of a jug or watering pot, until the fronds are freed from the soil. The Todea having a central crown should be planted in the usual way, with the crown just flush with the surface. The planting done, a gentle shower through a rose until water escapes from the tap will settle everything comfortably, and all that remains is to put on the glass cover, close the doors and top orifice, and leave it severely alone for several weeks, not even watering it, as, given such close conditions, the plants will not need it probably for months. Constant wetting overhead does more harm than good. For the ferns to thrive, even such shade-lovers as these, they are the better for plenty of daylight, but direct sunshine must be entirely avoided. The best position therefore is as close as possible to a north window, though a well-lighted hall table will do very well. Given such advantages, the case will slowly fill with beautiful translucent green frondage, while smaller spontaneous growths of moss, etc., will soon cover the "rocks," the healthy condition of which growths will be sufficient evidence that the watering has been adequate. Seedling ferns of other species will be fairly sure to present themselves, and these must generally be regarded as weeds, and extracted as soon as they assert themselves prominently, otherwise a crowd of conflicting plants will entirely spoil the effect. Such small-growing species, however, as the spleenworts, A. trichomanes, and others, may, of course, be left where they originate, or their spores may even be scattered, especially of their good varieties, to facilitate their appearance, but large species are entirely out of place in this scheme. For the mere purpose of propagating young ferns, cocoanut-fibre may be used instead of soil, and into this the spore pans, or small pots, containing seedlings can be buried up to their edges, and so long as the varieties are good and dwarf, very pretty results may be attained in cocoanut-fibre alone with specimens inserted in small pots at sufficient intervals to give them room. There is, however, no doubt that the Filmies are the best adapted, and give least trouble in the long run, if properly started.



MR. G. CRADDUCK.

Mr. G. Cradduck has on many occasions given ample evidence of his skill as a cultivator by exhibiting finely-grown examples of Acalypha hispida, Chrysanthemum Maud Jeffries, etc., at the Royal Horticultural Hall, and we have in these pages illustrated the fine nelumbiums and water lilies under his care at Bishop's Hall, Romford. Mr. Cradduck has charge of the indoor department at Colonel Lockwood's gardens, and finds therein ample opportunities for his robust energy and cultural ability. He has served under Mr. C. Fielder, V.M.H., at North Mymms Park,

near Hatfield, and under Mr. A. Bullock, at Copped Hall, Epping, and he is ever ready to acknowledge his indebtedness to these clever gardeners, who were always ready and willing to impart the knowledge they possess to those employed under them. Mr. Craddock is an exceptionally good plantsman, and in this connection he has the happy knack of making experiments that invariably succeed because they are based on keen observance and practical experience.

The Seed Industry.—In our next issue we shall publish an exhaustive and freely-illustrated article on the seed industry of the United Kingdom. The writer will deal with the various aspects of this important industry, and the article, with numerous illustrations of the more recently-introduced appliances for the preparation of seeds for distribution, should be of immense interest to all who are engaged in horticulture.

Messrs. E. Webb and Sons.—The business of this well-known firm, of which the late Mr. Edward Webb was so long the head, will be carried on by the surviving partners—Mr. W. Harcourt Webb, and Mr. Charles Webb—on exactly similiar lines as hitherto.

Market Gardeners' Compensation Bill.—In the House of Commons the other day Mr. Runciman, in moving the second reading of the Market Gardeners' Compensation (No. 3) Bill, said that it was all that remained of the provisions of the two Market Gardeners' Bill introduced earlier in the session, and whose object was to annul a legal decision which upset the custom of market gardeners, particularly in the Evesham district. As controversy had arisen in Grand Committee in connection with those Bills it was felt that whatever hope there was for setting right the matters affected by the legal decision would be jeopardised unless legislation was restricted to this one-clause Bill. The Bill was read a second time and committed to a Committee of the whole House.

Horticultural Club.—At the annual dinner of the Horticultural Club on Tuesday next the guest of the evening will be the Rev. W. Wilks, M.A., V.M.H., who has completed the twenty-fifth year of his occupying the position of secretary to the Royal Horticultural Society.

The Amenities of Windermere.—We are informed by Mr. S. H. Hamer, secretary of the National Trust, that an opportunity has arisen for purchasing on behalf of the public the beautiful property on the shores of Windermere, consisting of the hill immediately to the south of Millerground, known as Queen Adelaide's Hill, with its lake foreshore, and the wooded glen and stream. There is no isolated hill contiguous to the main road and accessible from the lake anywhere between Bowness and Ambleside from which such incomparable views of Windermere can be obtained. Not only is the whole of the lake northward seen, but looking south the eye passes over the whole of the indented shores and wooded islands as far as the Ferry, and is carried on beyond that to Gummershow and Lakeside, while the fells from Coniston Old Man in the west right round by Bowfell, the Langdales, Silver Howe, Fairfield, to the High Street range in the east, are visible. The trustees have given the National Trust an option expiring in June, 1913, to purchase the property, amounting to about twenty acres, for the sum of £5,000, which, in view of the prices for land obtaining in the neighbourhood, is not considered excessive. It is proposed to vest the property, if acquired, with the National Trust for the benefit of the nation at large. That the local public are interested in the matter is quite plain from the fact that before an appeal was made, £2,800 out of the £5,000 was locally promised.

Royal Agricultural Society's Flower Show.—As for some years past horticulture will occupy a very prominent position in the exhibition that will be held by the Royal Agricultural Society at Bristol from July 1 to 5. The flower show will be held from July 1 to 4, both days inclusive, and the schedule is comprehensive and liberal. The most important of the classes for plants is that for miscellaneous plants in and out of bloom occupying a space not exceeding 350 square feet. The prizes are £30, £25, and £20. There are also classes for groups of orchids, carnations, tuberous begonias, hardy herbaceous plants, and cut flowers, and for collections of cut roses, sweet peas, vegetables, and ripe fruits with correspondingly liberal prizes. Thirty dishes of fruit have to be shown, and to be decorated with flowers at the discretion of the exhibitors. The management of the show will, as in previous years, be in the hands of Mr. Peter Blair, Trentham Gardens, Stoke-on-Trent, and entries must be sent to him, the latest date for receiving these being Saturday, May 31.

Gardeners' Royal Benevolent Institution.—We have much pleasure in making the announcement that Mr. Leopold de Rothschild, C.V.O., will preside at the seventy-fourth anniversary festival dinner, which will be held on June 25, in aid of the funds of the Gardeners' Royal Benevolent Institution, of which he is a vice-president.

North of England Horticultural Society.—The close of the second year of operations of this society shows a paid-up membership of just over 500 Fellows and members, 16 affiliated societies, and a turn-over of £650. The increase in Fellows is nearly 50 per cent., and the number of affiliated societies has been doubled. The society is still handicapped by its heavy initial expenses, but in the coming year income and expenditure will, it is expected, balance each other. This year should see a great movement forward, as very few Fellows or members have fallen out of the ranks, except by death and inability to attend shows, and an appeal is to be made on a large scale. Various special sub-committees are taking matters in hand with keenness, chief among which is the new Magazine Committee, which will conduct the magazine on the "Round Table" method, there being sub-editors from each of the four main committees of experts, besides a chairman (Professor R. S. Seton) and a printing and advertisement secretary (Mr. T. H. Gaunt). The annual meeting will be held at the Queen's (Midland) Hotel, Leeds, on Wednesday, February 19, 1913, at five p.m.

The Love of Flowers.—The other evening Mr. W. Daniels, the superintendent of the Crows Nest Park, Dewsbury, gave a lecture, entitled "The Love of Flowers," at the Dewsbury Club and Institute. There was a large audience, and the lecture was of much interest. In directing attention to the additions that have been made to gardens during the past three centuries, Mr. Daniels said that since Lord Bacon's time the wealth of this country has increased beyond computation, and there could be no doubt that gardening and gardeners have kept fully abreast of their opportunities to promote and extend the purest of human pleasures. The wide world had been ransacked in search of stately trees and plants producing the most beautiful flowers, and every country and every clime had enriched our resources in this direction. Botany now claimed to be an exact science. Eminent and thus reliable botanists had computed at least one hundred and twenty thousand known species of plants, which are again divided into classes, orders, genera, and species—the latter again divided into varieties uncountable. It could be readily realised what this means to the gardener, knowing that the most beautiful in form, colour, and floriferousness of this stupendous mass of floral beauty is placed at his command, giving endless variety. So there could be no fear of our love for flowers becoming palled.

Mr. George P. Miln, the hon. general secretary of the Chester Society of Natural Science, Literature, and Art, and hon. secretary and treasurer of the Chester Paxton Society, has been appointed a magistrate of the city of Chester—an appointment which has afforded much satisfaction, more especially to the members of the two societies with which Mr. Miln has been so long associated.

Presentation to Mr. H. P. Pinkerton.—On the occasion of the annual meeting of the Irish Rose and Floral Society at Belfast advantage was taken of the opportunity for presenting Mr. H. Pinkerton, the secretary, with a testimonial as an acknowledgment of the services he has rendered the society. The testimonial consisted of a silver lamp and a pair of silver candlesticks, and the presentation was made on behalf of the members of committee by Mr. Alex. Dickson, of Belmont, Belfast.

Cornwall Daffodil Show.—The annual exhibition of the Cornwall Daffodil and Spring Flower Society will be held at Truro on April 8 and 9, and has the promise of being of exceptional interest. The Royal Horticultural Society has arranged to send a deputation, which will be authorised to award gold, silver, and bronze medals, and to grant certificates and Awards of Merit to such exhibits as they may consider worthy of distinction.

Rosa stellata.—With reference to this new rose, Professor Cockerell, of Boulder, Colorado, writes to "Nature" as follows: "In 1898 Professor E. O. Wooton described a remarkable new rose from Southern New Mexico, giving it the name of Rosa stellata on account of the stellate trichomes. The peculiar, mostly trifoliolate leaves, the leaflets with cuneiform bases and more or less truncate, sharply toothed apices, gave the plant an unusual appearance; while even the flowers, described as "large and showy . . . deep rose-purple," were not at all like those of the ordinary wild roses of the Rocky Mountains. Through the kindness of my friend, Professor Fabian Garcia, I obtained some living plants of R. stellata from the original locality in the Organ Mountains. Some of these were sent to Dr. A. R. Wallace, who has grown them in England successfully; the others have been growing in Boulder, Colorado. Last year the plants in my garden grew exceedingly well, and were most attractive. Certainly if R. stellata can be generally used in gardens, it will be a valuable addition to horticulture, but it probably will do its best only in relatively dry climates. My wife attempted crosses with several other roses, and in one case was successful in getting good seed; what will result remains to be seen. The fruit of R. stellata, as indicated by Wooton, is large, beset with strong slender prickles. Quite unlike the usual types of rose fruits, its walls are dense, not at all fleshy or brilliantly coloured, but corky.

The orifice is very broad, with a diameter of 8 mm. The bright chestnut-red seeds, about 4 mm. long, are long-oval, not compressed, and therefore not at all angular. All this differs conspicuously from the fruit of typical Rosa.

Pollination of Hardy Fruits.—To a recent meeting of the Linnean Society, Mr. Cecil H. Hooper contributed a paper of considerable importance on the pollination of hardy fruits, in which was embodied his observations on the insect visitors to the flowers. According to Mr. Hooper's observations, strawberries, provided there is wind, set fruit well without insects. Raspberries and loganberries set fruit imperfect in shape if insects are excluded. Currants and gooseberries, owing to the construction of their flowers and pollen, cannot be pollinated and set their fruit without the visits of insects. All these plants set fruit perfectly with pollen of the same variety, or even of the same flower; but in the case of the apple, pear, plum, and cherry, this is not always the case, many varieties being self-sterile, and almost all produce more abundant and finer fruit with pollen of another variety. In these trees there is little transference of pollen by the wind, and even if a self-fertile tree is enclosed in muslin whilst in blossom (there being ample movement of the wind, insects only being excluded), it is the exception for any fruit to set; it is the same with gooseberries and currants. In trials with apples, only nineteen varieties out of sixty-five proved self-fertile; in pears, four out of thirty; in plums, twenty-one out of forty-one; in cherries, five out of twelve; whilst, when cross-pollinated, in three-quarters of the trials one or more fruits set on a truss. There seems to be a preference as to pollen, some varieties setting better with pollen of one variety than with that of another; and some varieties will not set with certain pollen. Out of nearly 3,000 insects observed last spring visiting the blossoms of the various fruit bushes and trees, 88 per cent. were hive-bees, 5½ per cent. bumble and other wild bees, and 6½ per cent. flies, ants, beetles, wasps, and other insects; but the latter group have not fluffy bodies for carrying pollen, and amuse themselves by eating the pollen.

Peat Moss Litter Manure.—In the issue of the "Journal" of the Board of Agriculture for December, 1911, an article was published on peat moss litter manure in which Dr. Voelcker attributed the ill-effects of this manure to its acidity, and to the consequent unhealthy, imperfectly oxidised condition of the soil. In "Biedermann's Zentralblatt für Agrikulturcheurie" for November last reference is made to the foregoing article, and it is stated that good results have been obtained in the use of this manure in oher countries. It is contended that the acidity of peat moss litter manure is not too large to be neutralised by the bases of a normal soil without causing the reduction of Fe_2O_3 compounds into FeO compounds. Laboratory experiments were, it is stated, carried out at Jonköping with two samples of peat moss litter of marked acidity, mixed with various manures and examined when fresh, and when four weeks, six weeks, and three months old. In each case it was shown that the acidity of the peat moss litter was neutralised by the ammonia of the manure. At the experimental grounds at Flahult and Torestorp peat moss litter manure on both ordinary and moor soils gave good results with garden crops, both as a top dressing and when mixed with the soil. The manure is also much used by Swedish commercial gardeners for all crops. The advantages claimed are that it is the best material for absorbing excreta and for minimising the unavoidable loss of nitrogen in stable manure; that it has a deodorising and hence disinfecting effect on the manure; and that the manure made from it is more efficacious than when other materials are used as litter.

The Cultivation of Sweet Peas continues to occupy the attention of very large numbers of both professional and amateur gardeners; at this season of the year seed-sowing and the question of varieties are uppermost in the minds of growers, consequently "Sweet Peas and Their Cultivation," by Chas. H. Curtis, comes very opportunely, with its supplement dealing with the best varieties, new varieties, and giving other information that brings the book up-to-date. The book is a most compact and readable guide to the history, cultivation, and exhibition of the Queen of Annuals.

Physiological Effect of Bordeaux Mixture.—During the past five or six years experiments were carried out in Germany with a view to determine whether the increased yield resulting from spraying with Bordeaux mixture was due to a physiological effect on plants. In some experiments with potatoes, radishes, and beans, the crop decreased with an increased strength of Bordeaux mixture used. The mixture was found to have a favourable physiological effect only in dry weather, the mixture acting by hindering transpiration from the leaves. It was considered possible that the coating of copper sulphate also acted as a shade to the plant from an excessive amount of sunlight in hot, sunny weather, and thus prevented an early ripening of the haulm. The repeated spraying of currants and gooseberries with Bordeaux mixture had the effect of increasing the sugar content of the sap of these fruits. This was shown not to be due to the fungicidal action, as spraying immune varieties of fruits had the same effect; nor to any increased assimilative activity of the leaves, the latter, indeed, decreasing as a result of the spraying.

MESSRS. SUTTON AND SONS' FINE EXHIBIT OF GIANT CYCLAMEN AT THE ROYAL HORTICULTURAL SOCIETY'S MEETING.

Held on January 22, and awarded the Silver Flora Medal. The principal varieties represented are Giant White, Giant Crimson, and Vulcan, all of which are remarkable for the high development of their flowers and for their finely variegated leaves. For fuller particulars of this exhibit, see page 69 of our last issue.

THE CULTIVATION OF ONIONS.

Soil and Preparation.

The best soil for onions is a rich medium friable loam, though any good light soil, even if of a gravelly or silty nature, is suitable. Clay and clay loams should be avoided where possible, though moderate crops can sometimes be obtained on land of this type. Newly broken up grass land is quite unsuitable, not only because the crop will be liable to various insect attacks, but also because this soil produces "thick-necked" onions, that is to say, plants in which the parts above ground increase heavily in bulk at the expense of the bulb. Good results have, however, been obtained in the third season after the grass has been broken up.

The land should be thoroughly cultivated and freed from weeds before sowing. The importance of thorough cultivation cannot be over-estimated, and perhaps the greatest mistake in onion growing is the neglect of this precaution.

The soil should be cultivated in October or November, and left in a rough state, so that it may benefit from the action of frost during the winter. Some growers recommend deep "bastard" trenching, but others consider that a "one-spit" digging or ploughing of about nine inches in depth is sufficient. If onions are grown at all frequently on the same land, trenching is without doubt the better plan.

The choice between the two methods depends largely upon the rotation practised, and on the area grown. Generally speaking, for extensive field culture, ploughing to nine or ten inches is more practicable, while for cottage garden purposes deep digging is recommended.

A difference of opinion also exists on the subject of manuring. Some growers apply a dressing of good half-rotten stable or cow manure at the rate of, say, 10 tons to the acre, while others who are equally successful use artificial manures only. Some Bedfordshire growers have been known to apply as much as 50 tons of half-rotten stable manure per acre.

Manure should not be allowed to lie on the land for any length of time, as this encourages insects; fresh farmyard manure should never be used.

Where the grower has only stiff land at his disposal the advocates of deep trenching and the use of cow-manure recommend, in addition to a good dressing of short mellow manure, the application of a mixture of wood and cinder ashes with basic slag or lime, in the proportion of 7cwt. of ashes and 10cwt. of lime or basic slag to the acre.

It is not uncommon for onions to follow a crop of celery. The rotation in this case would be (1) Early potatoes or cabbage, the land being cleared in July; (2) celery; (3) onions. The advantage of this method is that the extra cultivation of the land, owing to the constant "moulding up" of the celery, and the heavy manuring of the trenches, bring the soil into an excellent condition to receive the onion seed. The land, as soon as the celery is off, should be dug and left until February or March. Good results may also be obtained with onions following corn, cabbage, carrots, or parsnips.

A dressing of 5cwt. of superphosphate, and from 3 to 4cwt. of soot per acre, is recommended by the Board of Agriculture immediately before sowing. Soot is particularly valuable. On light soils, which are apt to be deficient in potash, kainit at the rate of 5cwt. to the acre should be added.

In February or March the land should be reduced to a fine tilth.

For culture on a large scale the land is harrowed and rolled, and finally it is often raked by hand for the purpose of obtaining an inch of fine soil to receive the seed. For cottage garden culture the land is raked, then rolled or trodden firmly, and lightly raked again ready for sowing.

The importance of a firm seed bed cannot easily be exaggerated.

Sowing and After-Cultivation.

A day should be chosen when the land is dry and workable. The seed should be sown thinly in drills about 9in. apart and an inch in depth. The amount of seed required will be from 6 to 8lb. per acre, depending upon the variety and the size of the seed, which varies in different seasons. The seed must be raked in lightly, and the back of the rake is sometimes used for this purpose. The ground should then be rolled, and again directly the plants are up in the rows, if the weather is dry. The plan of raising the plants in autumn under glass and transplanting in spring is one that might well be adopted by small growers. One great advantage obtained by this method is the much greater freedom from attacks of "onion fly." Another dressing of soot or one of nitrate of soda is sometimes recommended at this point. Hoeing lightly is advisable to check seedling weeds and to aerate the surface soil.

As soon as the plants are large enough to handle, thinning should be commenced. The aim should be to have the plants ultimately from 4 to 6in. apart in the rows, but it is not usual to complete the process at one operation. The first thinning may be done by hand, but the labour is often reduced by using a 2in. hoe. The final thinning is given a few weeks later, and the plants then removed may be utilised for salad purposes. An advantage of prolonging the thinning in this way is that, even though a considerable number of plants are attacked by the onion fly in the early stage, the weight of crop is not necessarily seriously reduced, as sufficient sound plants may be left to give a full crop.

The hoe should be kept constantly in use, to prevent the growth of weeds. In a damp season, when the tops appear to be making too much growth, it is advisable to bend them over with the hoe handle or something similar. This should be done about the first or second week in August. It is not advisable to perform the operation too early.

Harvesting and Storing.

Towards the middle of August it is well to determine, by pulling up a few bulbs, whether the crop is ready for harvesting. If such be the case the bulbs come freely away from the soil, and the roots will be noticed to have withered. If new white roots are seen to be striking out from the bulb, the crop must be pulled without delay. This precaution prevents the possibility of what is known as second growth, namely, that of the new bud, lying between the swollen leaf bases of the bulb, and avoids the extra labour involved in lifting bulbs re-established by the new rootage.

Having determined when the crop is ready, the gathering should be done on the first fine dry day. A few rows are pulled, and the bulbs allowed to lie. Then the rows on either side of these are pulled, and the bulbs placed with those lying in the centre, so that as pulling proceeds there are alternate alleys of drying onions and of bare land.

During the drying, should the weather be showery, the bulbs should be constantly moved, to prevent second growth and the formation of fresh roots. When the bulbs are perfectly dry, they should be collected and stored either on a barn floor, or on specially constructed drying shelves. These shelves are placed along the length of the barn—one above the other, as in a book case—and are constructed of 3in. laths placed lengthways about 1in. or 1½in. apart, to allow the air to circulate freely. The crop should be occasionally inspected—to see whether there are any signs of "sweating" or dampness. If such be the case, the bulbs should be regularly stirred—a little experience will soon enable the grower to judge whether such stirring is necessary or not. Among small growers onions are often "strung" or "sticked" for storing, one method being to take a stick about a yard long and to bind the onions around the stick with string until the whole stick is covered. These sticks can conveniently be hung up in sheds.

Growing Pickling Onions.

There are several differences in cultivation when onions are grown for pickling. In this case, the soil is prepared in exactly the same way, but the drills are 7in. apart, and a much larger quantity of seed (up to 60lb. per acre) is used; no thinning of the young seedlings is required. Thus the density of the crop and the struggle for existence prevent the bulbs from attaining any but a pickling size. As a rule, however, large onion growers grade out the small bulbs from ordinary crops for pickling purposes rather than make a special cultivation.

In preparing for pickling, the small onions should be steeped in boiling water for a short time, then drained and allowed to cool. This makes peeling much easier. The onions, after being peeled, should be steeped in a strong solution of common salt for about a day, then carefully drained, and allowed to dry thoroughly. Finally, they should be put in bottles containing vinegar, which has been well spiced with cloves, peppercorns, coriander and ginger.

Production of Pickling Onions in Holland.

The growing of pickling onions on a large scale suffers rather severely from competition from Holland, and, owing to various representations made to the Board of Agriculture as to the serious effects of competition from this source, investigations were undertaken by the Board in the year 1902. These showed that the social and economic conditions under which the industry was conducted in the Netherlands differed in many respects from those existing in this country.

The secret of the success of the Dutch competition was, however, considered to lie mainly in the fact that the onions exported from the Netherlands presented, on the whole, a better appearance, and met more readily the requirements of the pickling firms.

Varieties of Onions Recommended.

(a) For Market Purposes: White Spanish, Bedfordshire Champion, Giant Zittau, Nuneham Park, Rousham Park Hero, James' Long-keeping. (b) For Pickling Purposes: Silverskin, Queen Pickling.

Board of Agriculture Leaflet.

Browallia viscosa.—This browallia, which has been seen a good deal of late, has proved to be just as floriferous in winter as in summer, and it should become very popular where flowers have to be maintained at all seasons of the year. The flowers are smaller than those of the better-known Browallia speciosa major, while they are of a much deeper blue, with a conspicuous white eye. This latter feature tends to brighten them up when seen in a mass. Browallia viscosa is readily propagated by means of cuttings, and also by seeds. Last summer it was very attractive bedded out at Kew.—K.

Sowing Peas.—Where the soil is of a light nature a sowing out of doors should be made at the earliest opportunity, selecting a warm, sheltered position. In dealing with heavy, retentive soils, sowings in pots, boxes, and turves will have to be resorted to; the seeds should be placed in gentle heat until germination takes place, and then be shifted to a cool frame near the glass. Air must be gradually admitted until the young plants are thoroughly hardened off, when planting-out may take place. The rows should be marked out, and the ground trenched, incorporating a good layer of well-rotted manure in each spit; a good dusting of bone flour and wood ashes may be added with beneficial results. When sowing outdoors no manure should be within five inches of the surface, for, should the seeds come into contact with the manure, they are liable to rot. For the earliest crops out of doors, Improved Pilot is one of the most reliable, while Pioneer (dwarf) is most suitable for narrow borders. Gradus may be sown at the same time for succession.—W. MESSENGER.

NEW PLANTS AND FLOWERS.

CATTLEYA ENID, VAR. FIRMIN LAMBEAU.

A very beautiful form of the hybrid between C. Mossiæ Reineckiana and C. gigas Frau Melanie Beyrodt. The flower shown was large and shapely, with broad, substantial, pure white sepals and petals, and a white lip, having a yellow throat and purple veins on the apex. F.C.C., R.H.S., January 21. Mons. Firmin Lambeau, Brussels.

LÆLIO-CATTLEYA FIRMIN, VAR. ARDENS.

A very handsome and brilliant lælio-cattleya, and though, as shown, not so large-flowered as the original, it had brighter colouring. The parents are L.-c. Ceres and C. Dowiana aurea. The sepals and petals are of a rich orange-red with a coppery shading, and the ruby-crimson lip has bright yellow markings. A.M., R.H.S., January 21. Mons. Firmin Lambeau, Brussels.

CŒLOGYNE INTERMEDIA.

This pretty hybrid cœlogyne is quite intermediate between its parents, which are C. cristata Lemoniana and C. Massangeana. The arching spikes are longer than in C. cristata, and carry more flowers, but the blooms are smaller. The flowers are white, with red lines on the lip, and a yellow disk. A.M., R.H.S., January 21. Messrs. Jas. Cypher and Sons, Cheltenham.

ODONTIODA MADELINE VAR. PRINCE OF ORANGE.

A remarkably distinct variety, showing how very possible it is to obtain quite new colours in odontiodas; indeed, we are only now beginning to understand the possibilities of odontiodas as decorative subjects. O. Madeline Prince of Orange comes from Odontioda Charlesworthi crossed with Odontoglossum crispum. A quite small plant was shown, and its rounded flowers were of O. crispum size and form, but of pale yellow colour, with large, light yellow-brown blotches; the lip is yellow with a red-brown blotch. A.M., R.H.S., January 21. C. J. Phillips, Esq. (gardener, Mr. Bucknall), The Glebe, Sevenoaks.

SOPHRO-CATTLEYA SAXA, ORCHID DENE VAR.

This is a finely-formed flower, and one of the best of its group. Rather over three inches across, and shapely, the flower is rich reddish rose, with a yellow base to the lip. A.M., R.H.S., January 21. Mr. E. H. Davidson, Orchid Dene, Twyford.

ROSE MRS. CHARLES RUSSELL.
A deep rose-coloured, fragrant H.T. variety; A.M., R.H.S., January 21. Mr. W. A. Manda, St. Albans.

ODONTOGLOSSUM AIREWORTH, GOODSON'S VAR.

This form of the hybrid between O. Lambeauianum and O. crispum, has broad segments and rounded flowers. The blush ground colour is freely marked with rich

purple-brown over the basal halves of the sepals and petals. A.M., R.H.S., January 21. H. S. Goodson, Esq. (gardener, Mr. G. Day), Fairlawn, Putney.

H.T. ROSE MRS. CHARLES RUSSELL.

A large-flowered, broad-petalled hybrid tea rose, of vigorous habit. The flowers exhibited were grown in the United States, and had been sent over in cold storage; they were full, fresh, and sweetly scented, and borne on stems 2½ft. long. The deep rose colour was, in many flowers, tinged with purple, but probably this shading was due to the journey and the lapse of fourteen or fifteen days since the blooms were cut. A.M., R.H.S., January 21. Mr. W. A. Manda, St. Albans.

CYCLAMEN ST. GEORGE.

A strain of salmon-flowered cyclamen, particularly remarkable for the silvery variegation of the foliage. In some plants the leaves had a wide and regular zone of silver, between the margin and the centre of the leaf, but in other cases the variegation was less regular, but none the less beautiful. As foliage plants alone these cyclamen are worthy of consideration. A.M., R.H.S., January 21. St. George's Nursery Company, Harlington, Middlesex.

NARCISSUS MINI-CYCLA.

A charming and dainty little hybrid between N. minimus and N. cyclamineus, the latter being the seed parent. It is a miniature trumpet daffodil of excellent proportions, the perianth having a spread of 1½ inches, with an elongated, frilled trumpet. The colour is golden-yellow, and the flowers stand five inches high on sturdy little stems. The elongation of the trumpet is the chief evidence of the influence of N. cyclamineus, though in one or two flowers the perianth segments showed a tendency to reflex slightly. A.M., R.H.S., January 21. Mr. F. H. Chapman, Rotherside Gardens, Rye.

SWEET PEAS FOR GARDEN DECORATION.

For all purposes of garden decoration the sweet pea must be considered and treated as a plant—that is to say, each seedling must be put out where a plant is wanted, and where it can have ample room to develop above and below ground. The careless grower, who turns out a potful of seedlings and thrusts sticks in their midst, then claims that he has arranged for a clump, will not experience any satisfactory results, no matter how rich the soil may be or how generous the after-treatment. Probably the best way to grow the sweet pea, for beauty and for size, is to give each plant a stick of its own, and locate it at least nine inches from any other plant. A charming effect is gained by giving each two sticks, slender bamboo rods, and latticing string between these, making a support a foot wide. When the main stem and side branches of foliage and bloom are tied out to these, the flowers and the natural grace of the habit of the plants can be perfectly appreciated.

A large bed in which these supports, with sweet peas trained to them, stand as much as three-quarters of a yard apart, may have a ground-covering of pegged-down verbenas, for example; scarlet and white, blue and blush, violet and salmon, rose-pink and crimson, white and carmine, primrose and purple are beautiful harmonies. The garden in which sweet peas are all cultivated in this fashion, either in beds as suggested or added to borders, will demonstrate how this favourite perfumed flower can be enjoyed without any faggots being tolerated. Many owners of ornamental grounds object strongly to the pea-sticks in such general use, and this objection is certainly one that can be fully respected.

When branched sticks are used it should be in such a manner that they are sure to be completely hidden by the summer luxuriance. Hedges or clumps will be found possible that are, to the eye, merely composed of plants, every twig being enveloped in growth; but to achieve this the sticks must be thinned out, no crossing or out-jutting branches being left, and the tops so bound together that they cannot be spread out by gales. Fine brown string is the best material to use for tying in.

Sweet peas on a slope are exceedingly beautiful, for the second row of plants will bloom about a foot below the chief blossom masses of the first row, and so on until the base is reached. This should be composed of the new bush sweet peas, that do not exceed two to three feet. Wherever there is a high hillock in the garden, if single plants of sweet peas, or well-made clumps, are dotted all over it, the colour display is sure to be glorious. Should the sides offer a very abrupt slope, some huge slabs of rock should be added at intervals, partly embedded in the soil in such a style as to arrest the washing down of the earth and manure mulches by heavy rain; and this will not only improve the appearance of the whole by imparting something of a natural look, but will also serve to maintain more even moisture over the whole surface. If the sides are turfed, round beds should be cut out to hold the clumps, the winter attractiveness being supplied by sunk evergreen or variegated pot shrubs.

A happy device is to make winding spiral paths up a high mound or bank of the garden, with a few wooden steps where necessary and leaving a plateau at the summit for a rustic bench. If this is rather low, the surrounding sweet peas will give shade, rendering the hidden nook a delightful one to occupy.

Perhaps the most triumphant employment of sweet peas was seen last season in a fine old moat. The whole base was given up to this plant, all the colours being used, well separated so as to harmonise, without any white or cream, so that the cheerful hues predominated. Seen from the level, the florescence looked like a brilliant low hedge. Seen from the windows of the house, the effect was of a diversely-coloured ribbon encircling the terraced courtyard. Two bridges over the moat had hedges of sweet peas on either side, to be walked or driven between; while the slanting banks showed extraordinarily vivid green, through being the permanent home of thousands of mossy saxifrages.

Sweet peas trained to fences can be cordially recommended. The sunniest positions are suitable; but if walls are similarly adorned, west or north-east aspects should be selected, as otherwise the bricks will become so hot as to to scorch the stems. Orange-scarlet sweet peas on old grey wood are especially charming.

Where temporary light screens are required, fish-netting tied to a few poles will afford a suitable hold for sweet peas, though some fastening of stems to the mesh will be needed. This has a more artistic appearance than wire-netting, and will not blow out with the wind if securely stretched. Growers must be cautioned against buying netting direct from fishermen, and employing it before it has lain exposed to the atmosphere for some weeks, as the salt may injure the plants. When wire-netting is used, it should be painted the pale grey-green of the foliage (not the ordinary green at all), or white.

M. H

POINSETTIAS.

These bright subjects have been more generally used in the arrangements of groups during the recent festive season than has been the case for many years, I think. Some really fine heads of bracts were to be seen in different parts from November onwards, and at the present time, at the end of January, the supply does not appear to be at all exhausted.

For many years I have grown these plants both under very hot conditions and comparatively cool. Thirty years ago, I was accustomed to keeping the plants in a fairly high temperature right through the summer. In later years I have, on my own account, grown them in cold frames, and, when the weather was not stormy at all, with the glass lights off night and day during July and August.

It will soon be time for dealing with the old plants and the cuttings, and a few hints on general cultivation may be useful to those who have not, as yet, had any experience with them.

The same kind of treatment is not followed alike by all growers, so I will only refer to my own.

I always grew on a few of the old plants in addition to young ones from cuttings. After the bracts had faded the plants were rested, but not kept in a too low temperature. An intermediate one I found best for them; water was withheld for a short time and the old plants to be retained were cut down to within 9in. of the base. In a short time young shoots commenced to push from the stem, and then water was given, and the plants placed in a light position. When the young growths were an inch long the soil was carefully shaken from the roots, and the plants repotted in smaller pots, just as fuchsias are often dealt with. Care was taken not to over-water the fresh compost, and, as it could be clearly seen which of the young shoots were going to grow freely (some never make progress) the weakly ones were rubbed off, and five or seven retained; sometimes it was found necessary to reduce the shoots on some of the plants to four, and even three.

The tips of the old stems were cut back in the case of some of the other plants, and young shoots, to form cuttings, were encouraged to grow lower down. These young shoots were taken off with a small heel attached and inserted singly in small pots, filled with a sandy compost, and placed in a propagating frame. The old plants, denuded of their cuttings, were then thrown away. So I had two batches of plants growing; one from old stems, to form specimens bearing from three to seven heads of bracts, and the other, single-stemmed plants, bearing one head each.

Light, fibrous loam and leaf-soil in equal proportions with plenty of coarse sand will make an excellent compost for the cuttings. More loam than leaf-soil, with a small quantity of old shed-dried cow manure and a 6in. potful of old mortar rubble to a bushel of the compost, will do nicely for subsequent repottings.

In their early stages the young poinsettias are best grown in a summer temperature and a fairly moist atmosphere. In July and August frame treatment; then housing the plants about the middle of September.

I like to feed regularly after there are plenty of roots formed in the flowering pots, giving frequent but weak doses of soot-water and approved chemicals, with occasional applications of ordinary manure water. When the plants are housed care must be taken not to give them a check through inattention to watering, ventilating, heating, etc.; or else many lower leaves will be lost.

GEO. GARNER.

CARE OF PEACH TREES AFTER FRUITING.

An observation was made recently in the GARDENERS' MAGAZINE to the effect that the splendid condition of certain fruit trees was due to the care bestowed upon the trees after they had fruited. I am quite sure that this touches a very weak spot in connection with fruit culture in private gardens, and especially in connection with peach trees grown in the open.

I do not think anyone will attempt to refute the assertion that out-of-door peach culture is not so largely practised or so well managed at the present time as was the case two or even three decades ago. Much blame for want of success is heaped upon the weather, and employers are induced to cover the walls with glass for the sake of the peach crop.

True, even now we come across successful examples of open-air peach culture, such as that at Frogmore and Aldenham, which are splendid examples of what can be achieved by care and attention, and which certainly can be copied.

One of the greatest errors committed in outside peach culture on walls is that of failing to supply the trees with sufficient moisture at the roots after the fruits have been gathered, especially if there is a spell of dry weather about that time. Too often the trees are forgotten after they are cleared, until they are showing signs of new growth in the spring. Little thought is given to the capacity of a brick wall for absorbing moisture from the soil, to the detriment of the trees, and so the roots are not able to supply material for storing up the necessary nutriment for the production of fruit buds in a proper condition. A careful cultivator will note the condition of the roots of the trees during the months of September and October, periods when nourishment is as much needed as at any stage of growth. If the rainfall is not sufficient artificial watering must be given.

Vegetable crops are very often grown in front of the trees, and these need quantities of manure into which the roots of the peach trees penetrate, and so useless vigour is induced in the trees. Such exuberant growth, if not corrected, is liable to do much harm. Under such conditions an annual trenching of the border to within four feet of the wall is imperative to sever the strong roots, and induce those of a more fibrous character to be formed.

Too often we see tall herbaceous plants growing in front of the trees to within a yard of the wall, and these rob the surface roots of the peach trees of nutriment. Helianthuses, solidagos, Michaelmas daisies, and such-like exclude sunlight and air from the trees, thus preventing that natural maturation of the current year's growth which is an absolute necessity in the case of peaches and nectarines.

Delaying the pruning or partial pruning of the trees until the month of March is all too common, but is not for the welfare of the trees. If the primary branches and shoots that need removal were cut out directly the crop is gathered the remaining branches would benefit by free exposure.

E. MOLYNEUX.

CYCLAMEN ST GEORGE.

A strain with salmon-coloured flowers, but most remarkable for the fine silvery variegation of the leaves. A.M., R.H.S., January 21. St. George's Nursery Company, Harlington.

AUTUMN-FLOWERING ROSES FOR NORTHERN CARDENS.

In the case of deferred planting, the roses when received should be carefully inspected, and any very lengthy or evidently superfluous shoots be reduced to a moderate extent; the same process may also be followed with any rough or broken roots. The plants may then be placed in a shallow trench, formed in any good friable soil, and be covered with the finer portions thereof to the same depth at which they were before removal, and all pressed firm.

Should very severe weather occur, leaves, litter, or fern shaken about them might be beneficial, though such aid is seldom required.

The Best Varieties for Autumn Flowering.

These notes were prompted by the frequent enquiries that are annually made as soon as an early frost strips the flower garden of much of its beauty, but leaves the roses practically unharmed. So many folks want to know the best and most reliable varieties for carrying on the supply of flowers long after the summer blooms are past, or, to be more precise, until the end of October in normal seasons.

It is at once apparent that the best classes of exhibition roses cannot be depended upon for this, though odd blooms may occasionally be in evidence upon them; hence it is to the garden or bedding roses that one must turn to obtain what is desired. During the rose season now practically closed I have paid particular attention to a fair-sized collection of varieties, most of which, however, are well-tried favourites and needed but little scrutiny to reveal their respective merits, which were pretty well-known beforehand.

The collection referred to comprises about a thousand plants, and nearly all are dwarfs; probably about half this number are of the hybrid perpetual class, the majority of the remainder hybrid tea, Bourbon, and China varieties, and all were selected, when purchased, for their freedom of flowering and general usefulness for display as growing or for cut blooms for room decoration. For the latter purpose several good-sized vases have, up to the present (October 25), been utilised and kept replenished thrice weekly, in a pleasing variety of colouring; and table decorations worked out entirely with roses and rose foliage have on several special occasions during the month been carried out, to the evident delight and wonderment of the assembled guests.

To obtain good flowers in quantity possessing the richest perfume thus late in the season may to some appear a difficult matter, but such is not the case in most country districts, and cultural methods do not enter very largely into the subject. What is needed is a selection of varieties adapted for the purpose, and to plant these in sufficient numbers to meet the requirements of the establishment.

Twelve Reliable Hybrid Tea Roses.

Caroline Testout. Bright rose; large open flower, shell-shaped petals: flowers usually produced in well-spread clusters. One of the very best at all seasons.

Madame Abel Chatenay.—Carmine rose, changing with age to light pink, or late in season almost white; erect in growth, and one of the latest to flower.

Gustave Grunerwald.—Deep pink, with yellowish markings at the base of the petals. The flowers are well supported and withstand the autumn storms with little or no injury. The best of any of its colour.

Madame Ravary.—Golden-yellow, very free flowering, and may be considered the finest yellow rose for outside culture. The exact tint of the colour varies with the season, but is always attractive.

La France.—Pale flesh colour, very highly perfumed and free flowering. In very wet or adverse weather the buds do not open freely, a fault that seems more pronounced than formerly. Still it is one of the best, as a few hours of sunshine amid storm will reveal.

Lady Battersea.—Light crimson, changing to rose as the flowers expand. The blooms are borne on long, straight stems which renders them very convenient for decorative purposes. The foliage, too, is of the best and is retained upon the stems for a long time.

Mrs. Aaron Ward.—Bronze-yellow in general, but very variable, at times several distinctly coloured flowers may be taken from one plant.

General McArthur.—Dark red flowers of large size, well-shaped, and freely produced throughout the season; perhaps the best dark rose in the hybrid tea class. Foliage also large, green, and of good substance, while the perfume is superb.

Ear of Warwick.—Salmon-pink; flowers large, and of good form, a grand late variety.

Lyon Rose.—Apricot. An attractive flower at any season, particularly so in late autumn, when the intensity of colour is splendid; growth of plant rather open or straggly; well adapted for the centre of a bed or mass.

Augustine Guinoisseau.—Pure white on opening, afterwards faintly tinted with rose; very distinct and valuable for cutting or garden embellishment.

Betty.—Coppery-rose, changing to yellow as the flowers open. A charming variety that should be included in every collection of plants. It is also one of the latest, flowering well into November generally.

To these may be added, if greater variety is desired, such standard sorts as Viscountess Folkestone, cream-pink; Liberty, crimson; Mrs. Theodore Roosevelt, creamy-white; Papa Gontier, rosy-crimson; Richmond, crimson-scarlet; Killarney, light pink; Marquis de Sinety, yellow and red; and Prince de Bulgarie, silvery-pink.

Hybrid Perpetual Varieties.

To accompany the foregoing some of the hybrid perpetual varieties are worthy of a place for their fine appearance and late-flowering properties, besides which, if used with the H.T.'s for decorative purposes, their more formal habit and pose, together with their sturdy foliage, provide a contrast that results in one class contributing in a somewhat indirect way to the enhancement of the other.

The popular Frau Karl Druschki continues to flower as late as any rose upon plants that are allowed a fair amount of freedom, and the purity of the blooms, though scentless, elicits admiration from all.

Ulrich Brunner, cerise red, is beautiful in all its stages of development and colouring, and when placed within the range of a brilliant illumination, possesses a charm peculiarly its own.

Captain Hayward, dark crimson; Mrs. John Laing, pink; Abel Carriere, purple crimson; Dupuy Jamain, cerise; Fisher Holmes, scarlet; General Jacqueminot, crimson; Duke of Edinburgh, vermilion; and, lastly, the old favourite Madame Victor Verdier, having rather small pointed buds, crimson in colour, freely produced, and well adapted to withstand inclement weather, are all excellent autumnal flowerers that should be largely planted in every garden.

JAMES DAY.

Galloway House, Wigtownshire.

THE FORSYTHIAS.

Few, if any, of the flowering shrubs of early spring are so beautiful as the forsythias, which during March and April are thickly studded with their soft yellow blossoms that prolong, in a paler tint, a display of the same colour afforded in the opening days of the year by the winter jasmine.

Of the two species, Forsythia suspensa is, perhaps, the more valuable, as it is eminently adapted for clothing a wall; while, if given adequate support, and allowed to develop its gracefully-arching shoots, it forms an exquisite picture in the open ground. In training this forsythia against walls only the main shoots should be fastened in, the more slender shoots being allowed to droop naturally. Treated in this manner, a wall planted with this subject presents a veritable cascade of gold in the blossoming season.

Forsythia viridissima is of upright growth, and forms a handsome shrub, which naturally attains a greater height than F. suspensa grown in the open, since the shoots of the latter are pendulous. Large, well-furnished bushes, 10ft. or so in height, add greatly to the attractions of the spring shrubbery. Both forsythias should be planted in positions where they may enjoy the full sunshine, as it is only when the wood is well ripened that an abundance of flower is produced.

Any pruning necessary, which should be confined to the thinning out of old and weak growths, is best taken in hand immediately the flowering season is past. When allowed to ramble at will in elevated positions in the wild garden, Forsythia suspensa is perhaps seen at its best. A striking instance of this was where a plant growing at the top of a low cliff-face had hung a veil of golden blossom over the rugged rock, presenting a picture charming both in colour and form. There is a reputed cross between F. suspensa and F. viridissima, to which the title of F. intermedia has been given; but it is doubtful if this is more than a form of F. suspensa, in which the drooping habit is less pronounced.

WYNDHAM FITZHERBERT.

The Oyster and Mussel Scales. — The plum is subject to the attack of the Oyster and Mussel Scales; the last-mentioned is a pest which, if allowed to increase, saps the vigour of the tree to a considerable extent, and also disfigures the fruit by its unwelcome appearance. During the dormant season the affected branches should be scrubbed with a stiff brush, using a suitable insecticide to loosen the scale. Paraffin emulsion will be found to answer the purpose. Where shreds are used they should be replaced annually and the old ones burnt. — W. MESSENGER, Woolverstone Park Gardens.

PERENNIAL EVERGREEN CANDYTUFTS.

The evergreen forms of candytuft (iberis) are remarkable for their wealth of blossom in spring, and they comprise some of the most useful for clothing dry and arid positions, often disclosing their beauty under conditions where little else would grow. They are among the easiest subjects to propagate. Seed and cuttings, as the case may be, offer a ready means of increase, and good strong plants can be obtained within the year. One of the most familiar and reliable species is

Iberis sempervirens, of which there are numerous garden forms, differing chiefly in the habit of the plants. The type forms a spreading sub-shrub, which frequently attains a breadth of several yards. The leaves are dark green, and persistent, on thin twiggy branches, from which, in May, the flowers are produced in such abundance as to present the aspect of a veritable snowdrift. The individual flowers are white, and are arranged in circular, umbellate heads. Little Gem is a miniature, compressed form, only three inches high, and choice enough for the best type of rock garden, where, on sunny slopes, it makes a close carpet of verdure, and in season arrays itself with its pretty snow-white flowers. Snow Queen is larger, forming a neat and attractive plant some nine inches in height. The flowers are white, and of a large size, and it commends itself for planting on bold promontories of rock gardens.

I. correæfolia is a vigorous garden hybrid. The individual flowers are of the largest size, and as the compound heads elongate with age they assume a massive aspect. It is one of the best for the front edge of borders and shrubberies.

I. gibraltarica produces exceedingly large flowers, which are tinted a delicate shade of rose-lilac. It is a beautiful and effective subject, succeeding best in dry walls and as one-year-old plants, as after this it becomes very straggly.

I. saxatilis is another miniature species, some four to six inches in height. It is one of the oldest and prettiest of the evergreen candytufts. THOMAS SMITH.

LÆLIO-CATTLEYA FIRMINI VAR. ARDENS.

One of the showiest of lælio-cattleyas, with a combination of orange-red, ruby-crimson, and yellow colouring. A.M., R.H.S., January 21. Mons. Firmin Lambeau, Brussels.

THYMES FOR THE ROCK GARDEN.

The Garden Thyme (Thymus vulgaris) is a well-known fragrant plant in all gardens, being much valued on account of its strong aromatic odour. It is recorded as having been introduced into cultivation about the middle of the sixteenth century, but was probably grown here long before that time. It is a native of Southern Europe, and is especially abundant in Spain, a country that is said to be peculiarly favourable to the growth of all sweet herbs. The genus comprises several species, chiefly found in the Mediterranean region and Central Asia, and the most universal member of the genus being the Wild Thyme (T. Serpyllum), which is found on dry banks, and in hilly pastures throughout Europe and temperate Asia. It is very abundant in this country, forming beautiful dense green carpets that are a delight, both to the sight and to the touch. When the passing foot bruises the leaves, they exude a sweet fragrance that is ever a source of pleasure. In cultivation the carpeting thymes will thrive anywhere in the sun, especially in the crevices between rocks, on old walls, or in the angles of rough-made steps, while they comprise some of the most useful plants for growing between the joints of stepping-stones or flagstone paths.

There are several species of thymus in cultivation, but the majority bear a very great resemblance to each other in habit of growth and general appearance. When in favourable quarters they are rampant growers, soon covering large areas. One of the most distinct is

T. azoricus, a charming little plant from the Azores, which might be described as a diminutive shrub. The stems are quite woody, but prostrate and much branched, covered with light-green foliage. It is most at home on a rocky ledge in full sun, so that the stems are pressed against the stones. Then it forms a dense turf-like plant, covered in summer with pretty purplish flowers. Although coming from the azores, it is quite hardy when planted on rocky ledges.

T. varnosus.- -This is a shrubby species of erect habit from Spain, with fragrant greyish leaves, and white or pale-purple flowers. It is useful as an evergreen for the rock garden.

T. Chamædrys. — By many authorities this is considered merely a form of the Common Wild Thyme, but it differs in that the branches are all ascending from the root-stock, while the whorls of flowers are in axillary heads. In growth it is dwarf and neat, with light purple flowers. Several varieties of this are offered in catalogues; T. C. var. comosus having larger rounded leaves and darker-coloured flowers, while T. C. var. nummularius has erect spikes of bright rosy flowers.

T. Herba Barona. .The Corsican Thyme is remarkable for a distinct odour, which resembles nothing more than caraway seed. It is of spreading habit, with twiggy branches, somewhat more erect than the last. A rare plant, it is confined in its native habitats to the Island of Corsica, where it takes the place of the common thyme. Neither is it common in gardens, although plants have recently been introduced in cultivation.

T. odoratissimus.—The Russian Thyme, which is admirably shown in the accompanying illustration, is one of the handsomest members of the genus. It is of free spreading habit, with prostrate ascending stems, terminating in long inflorescences of pale-purple flowers. From six to nine inches high, the plant is covered with flowers for the greater part of the summer, while it possesses a powerful fragrance which suggested the specific name. Like the last, this is a recent acquisition, having been introduced to cultivation by Mrs. W. H. Stansfield, of Southport, a few years ago.

T. Serpyllum, the Wild Thyme, is a delightful native creeping plant, with slender, much-branched stems that are woody at the base. It forms low dense turfs of herbage, from a few inches to several feet in diameter, covered in summer with its purple flowers. Of this there are many varieties grown, ranging from a pure white, T. S. var. albus, to T. S. var. pulchellus, which is here illustrated, with rich rose-purple, or almost crimson flowers. T. S. var. lanuginosus is a form with leaves clothed in soft grey, woolly hairs, and very attractive with lilac flowers. Other varieties are: Coccineus, with crimson flowers; and splendens, with bright red ones.

THYMUS ODORATISSIMUS.
A sweet-smelling thyme, rather strong in growth, and bearing lilac-coloured flowers.

The members of the thyme family are amongst the easiest of all plants to manage in cultivation. They may be propagated by division in the autumn or spring, or raised from seeds, which most of the different kinds produce freely. The latter method, however, would not be advisable in the case of bright-coloured varieties, which it is desired to increase. Cuttings root readily at any time during the summer, if kept in a close frame for a short time.

For the rock garden there are no more useful plants, as they may be used for covering stony banks where little else will grow, and they are charming when seen in such masses as are shown in the illustrations herewith. W. I.

FLOWERS FOR CUTTING.

The present-day demand for cut flowers is very considerable, and in some places taxes the resources of the gardener to the uttermost during the winter months, and not a few have a great difficulty in keeping up a supply. True, many plants bloom at this period of the year which do not need much forcing to induce them to expand their flowers, but all are not suitable for cutting. We might mention some of the early-flowering shrubs by way of example; these, such as deutzias, soon shed their flowers when put in water in a warm room. What one requires for cutting is something light and effective when set up, and that will last for several days in the atmosphere of a hot, dry room. To enable flowers to do this there must be some substance in their petals, and very few of the hardy shrubs possess this when forced into bloom; the flowers will last fairly well on the plants, but when cut and stood in water they soon fade or wither up.

The most useful flowers for cutting are those having fairly long stems, though, in some instances, for small vases, this need not be taken into consideration. Some of the anemones are very useful, though they are somewhat heavy in appearance, but if grown in frames or boxes where a very slight degree of warmth can be provided the plants will bloom most profusely. It is advisable to raise a batch of seedlings each season for this purpose. If the seeds are sown in spring, and the plants grown through the summer without a check, they will bloom freely through the winter and early spring months. When the seedlings are large enough to handle they may be pricked out into boxes in which they are intended to bloom. The boxes should be at least six inches deep and should be of a handy size so that a man can readily carry them about. If stood close together during the summer in a sunny position the plants will keep growing and by the autumn will have attained sufficient strength to enable them to throw up strong flower stalks. If the boxes are moved into a cool house at the approach of winter the plants will continue to give a supply of flowers.

All who have had much experience in floral decorations are well acquainted with the usefulness of the early-flowering irises, but though these naturally bloom very early, they will not put up with much heat. Those who are desirous of having them in bloom thus early must plant in good time, and keep them growing very slowly. Iris reticulata is very beautiful when well grown. The Spanish iris, too, are most useful, but these should be grown in separate colours. The narcissi are so common now that most people grow them, but the whole secret of success in having the flowers to last is early potting, and keeping the plants growing gently from the time the roots are formed. It is useless to pot up the bulbs in October and expect them to produce strong flowers at Christmas. Plant well-ripened bulbs early in August, and when rooted place them in a cold frame, and they will then be sending up their flower spikes about the time some people think of potting.

Many years ago, when under Mr. Taplin, at Enville, I was taught a lesson that I shall never forget, which was, "always be abreast of the times, and, if possible, in advance of them." It is this being first in the field with produce that enables a man to command the best prices; there is often no advantage in waiting until the usual time for doing certain things; it is far better to strike out a line of one's own.

There are now many useful hardy annuals that are great favourites for cutting, and as these are inexpensive to grow, a few might be added to the list for the production of cut flowers early in the season. There is now a large number of shades of schizanthus, and these are charming things for cutting. If sown early in the autumn they may be had in bloom in February with but little attention. Nemesias, also, grow quickly, and are of but little trouble. There are many others too numerous to mention, which could be grown by those possessing a cool house, but the above-named will be sufficient to show that with those who have but small convenience it is possible to make a display.

Among the foliage plants useful for greenery there is nothing, in my opinion, to equal Ruscus racemosus. This is a plant that will produce fine sprays of vivid green foliage that will last a considerable time in water. Plants may be grown in the shrubbery, where, during the summer, they are most attractive. In the autumn they produce a quantity of red berries, and these, if gathered as soon as ripe, and sown in a cold frame, will in time produce plants. The seeds are some time in germinating, and the plants grow slowly at first, but when established make shoots from two to three feet long, having finely-pointed leaves, somewhat resembling those of the smilax. H. C. PRINSEP.

THYMUS SERPYLLUM PULCHELLUS.

A beautiful variety of the wild thyme with brilliant rose-purple flowers.

Mr. F. Bennett, gardener to Captain Glyn, has been successful in winning the Royal Horticultural Society's medal, which was offered as a prize for the member of the Wimborne Gardeners' Association who obtained the highest number of points for exhibits at the society's meetings during the past year.

THE ROYAL NURSERIES, HANDSWORTH, SHEFFIELD.

There are nurseries in Great Britain that may justly be counted old-established, a number that are of great extent, some that are famous as having been the birth-place of valuable and beautiful trees, shrubs, fruits, or stove and greenhouse plants. Many honoured men and great horticulturists are numbered among the founders and proprietors of nurseries in this land of ours. Certain firms are celebrated as specialists in fruit, others in ornamental trees and shrubs, hardy plants, or particular classes of exotic and tender plants, the clientele extending from end to end of the kingdom, and even to distant countries, but every one of these distinctions may well be claimed by the Royal Nurseries, Handsworth, Sheffield, belonging to Messrs. Fisher, Son, and Sibray, Lim.

A hundred and sixty odd years is the length of this firm's career, during which time the growth of the business and extensions to the nurseries have been such as to make the establishment one of the largest in the trade. Some idea of the size of the Handsworth Nurseries may be gathered from the fact that there are about seven miles of cart-roads within its boundaries, and it may certainly be said that all classes of plants are here grown on a large scale. To name and describe all the choice varieties of trees and shrubs that claim this nursery as their birthplace would be no small task, and from the big range of glass-houses some of the most handsome crotons and dracænas have been distributed, as well as some exceedingly fine anthuriums.

Hollies, as most people know, are a great speciality of the firm, the several home-raised varieties being everywhere recognised as among the most handsome and useful in cultivation. The "mother" trees of these hollies are a feature of exceptional interest, there being quite a number of tall, stately specimens still full of vigour, maintaining splendid symmetry, but, of course, not possessing the remarkable beauty of foliage which characterises their progeny. Indeed, it affords a striking object-lesson upon the real value of the plant-breeders' painstaking efforts to compare the choice named varieties of hollies which have helped to make these nurseries famous, with the old types from which they have been evolved. Our common green holly (Ilex aquifolia) is a grand tree, but, as everybody knows who is at all acquainted with hollies, we have many varieties that are infinitely superior to it, and for a number of the best among them we are indebted to Messrs. Fisher, Son, and Sibray. Ilex Wilsoni deserves a special word of praise, not only on account of its splendid dark green foliage, but for its vigour and perfect habit. This was the first, if indeed it is not the only, green-leaved holly to receive a First-class Certificate from the R.H.S., and right worthily does it hold this distinction. I. Wilsoni is grown in immense quantities, many fine specimens being seen, as well as thousands of vigorous young plants that are laying the foundations for good trees of the future. Handsworth New Silver is another variety of which its raisers may well be proud, for surely no one wants a more delightful variegated variety than this. I. Handsworthensis, a small-leaved green variety, has its particular charms, and another of the "Fisher" group is I. Mundyi, which has large leaves of a bright glossy green, and grows into beautiful pyramids with very little pruning. The collection includes all the best hollies in cultivation, I. Shepherdi, otherwise known as Hodginsi being obtainable in any quantity and any size, from young plants a foot high to big specimens. There is nothing about which Messrs. Fisher, Son, and Sibray are so extremely particular as the periodical transplanting of their stock to ensure the abundance of fibrous roots, that alone will render successful removal possible even in the case of very large trees. It is worth mentioning that the first propagated plant of I. Shepherdi may be seen growing in the nurseries to-day, so that, although not actually raised here, this popular holly has from the beginning been closely associated with the nurseries. Altogether there are over fifty named varieties of hollies in this collection, and the greatest care has been exercised in regard to accurate nomenclature.

On either side of a straight walk a quarter-mile in length, grows a magnificent lot of golden yews. There are trees of all shapes and forms, but all beautifully developed, and of very effective colouring. Fisher's variety of the Golden Irish, and Taxus grandis, another home-raised form, possess characteristics that mark them out from their many companions, but T. Dovastoni variegata, elegantissima, laevigata, and several others are excellent in every way. If we do not write at length upon the abies, the cupressus, and all the other conifers, it is simply because there is so much else that demands notice, and it is difficult in one brief review to decide what to mention and what, of necessity, to pass over. The flowering shrubs alone would furnish material for an exhaustive article, the rhododendrons being exceptionally meritorious. It may be that good varieties of rhododendrons exist which are not to be found in this collection, but we may say, with all confidence, that the best of the Handsworth collection are the best in cultivation, and are grown on a large scale.

The soil suits them, the propagators are experts at their work, and the same watchful care in regard to periodical transplanting, as was noticeable in all departments, has kept the whole stock in capital condition, so that even big, well-developed plants measuring as much as six feet in height may be removed with scarcely a shadow of risk. The beautifully balanced standards of Pink Pearl arrested our attention, and conjured up in our mind's eye pictures of loveliness that they would present when in full bloom, for, without a doubt, it is on standard plants, which raise the trusses of bloom to the level of the eye, that this glorious rhododendron is seen to greatest advantage. Countess Fitzwilliam, a variety introduced by Messrs. Fisher, Son, and Sibray, is a bright and very attractive variety, bearing big trusses of carmine-tinted flowers with dark spots. Another of the firm's raising is Duchess of Portland, a variety that has strong claims to the distinction of being accounted one of the best white-flowered hardy rhododendrons in commerce. The hardy ericas constitute another most interesting feature, and the berberis, including all the finest species and varieties, and many extremely beautiful seedling forms of B. aquifolia, provide both foliage and flowers that may grace the finest shrubberies or borders.

A most charming shrub that can scarcely be over-estimated is Phillyrea Vilmoriniana, with large foliage and fragrant white flowers. That it is held in high esteem may be gathered by the extent to which it is propagated at Handsworth, and I was informed that there is always a ready sale for this highly effective shrub. Shrubs that bloom late in the season are especially valuable, and on this account we made a note of Cytisus nigrus hirsutus, which, even in November, carried a good show of flowers. There were also any amount of berried plants, such as pernettyas, cotoneasters, and gaultherias, which do so much to brighten the garden when flowers are scarce and the days are dull.

We were much interested in the Handsworth variety of the purple sycamore, and Salix vitellina aurea pendula, an exceedingly graceful weeping willow that certainly merits a place beside even the most ornamental of lakes or streams. Golden elms, scarlet and double white chestnuts, silver birch, and the Handsworth limes, are all available in magnificent young trees. A big stretch of Quercus palustris, the marsh oak, comprised a fine lot of this distinct and noble tree; and a batch of tall, shapely trees of Cotoneaster frigida, ranging in height from five feet to ten feet, was of much interest. The Wheatley elm, one of the best street trees in cultivation, is largely grown for this particular purpose, and, of course, plane trees are also grown and strongly recommended for town planting. Purple beech, erect and weeping poplars, Japanese maples, thorns, and, in fact, every kind of tree is represented.

Herbaceous and alpine plants are extensively grown, and there are capital show borders on either side of a very long walk, where one may see good clumps of all the kinds stocked growing and flowering under admirable conditions. So, too, there are borders of shrubs arranged for effect, and beside a very pretty piece of ornamental water all sorts of ornamental willows, gunneras, gyneriums, and bog plants are grouped in a natural and effective manner.

The glass department of the nursery is of great extent, most of the houses being long, broad, span-roofed structures capable of accommodating very big stocks of plants. Crotons are very well grown, and included in the comprehensive collection are a number of very beautiful varieties which have originated in this establishment. One of these, named Duke of Portland, is a fine broad-leaved variety of capital habit and rich colouring; and a new pendulous form of C. Heathi elegans is exceedingly graceful. Interesting also was a batch of Dracæna australis, among which some very distinct and handsome forms — all home-raised — were noticed. Orchids are grown, and most of the more popular greenhouse flowering plants are produced on a large scale. Anthuriums have for many years been a big feature with Messrs. Fisher, Son, and Sibray, and those of our readers who saw the magnificent group of these gorgeous plants which the firm exhibited at the International Exhibition will not readily forget it.

This establishment has a large seed and bulb department, with a spacious, well-appointed warehouse, in a prominent position in Sheffield, and a big agricultural as well as horticultural seed trade is done.

East Lothian Stocks. — These stocks are not so freely used in the South of England for summer bedding as they are in the North, and when one considers their usefulness for such work, it seems rather surprising, as they flower continuously from July until well into the autumn. When growing them for this purpose, the seeds should be sown at once in shallow pans or boxes and placed in a gentle heat to germinate. When the seedlings appear give them a position close to the glass in a cool house, and as soon as they become large enough to handle pot them off singly, using large 60's, and grow them on in a cool-house or pit until well established. Then remove them to a cold frame, giving plenty of air on all favourable occasions, so that by the time they are ready to be planted out in their summer quarters they will be well hardened off. Seeds of these stocks can be obtained giving distinct shades, and if procured from a reliable source the flowers can be depended upon to come true to colour. This is a decided advantage when planting masses of separate colours, in which, by the way, these stocks are seen at their best. A very desirable white stock named All the Year Round produces an abundance of bloom from June until Christmas, should the autumn prove mild, if treated in this manner.—T. B. FIELD.

PEARSONS' RELIABLE SEEDS.

MAUD HOLMES.

SWEET PEAS.

After making hundreds of trials of Sweet Peas, and having examined many more hundreds on various seed trial grounds, we make the following selections for the guidance of those who have not had the opportunity to closely study and compare the vast army which is now in cultivation.

THE 12 BEST DECORATIVE SWEET PEAS for 2/6.

	Seeds.		Seeds.
Evelyn Hemus	25	John Ingman	25
Flora Norton Spencer	25	King Edward Spencer	25
Helen Lewis	25	Lady G. Hamilton ...	100
Helen Pierce	100	Nora Unwin	50
Hon. Mrs. Kenyon ...	100	Queen Alexandra ...	50
Mrs. Hugh Dickson ...	25	Othello Spencer	25

The EXHIBITOR'S COLLECTION

12 Splendid Varieties for 5/- ; post free.

We offer all the choicest stocks of **Vegetable and Flower Seeds** at the **Lowest Profitable Prices.** We feel confident that many amateurs now paying from 25 to 50 per cent. more than we charge would, if they gave us a trial, find the results equally good, and they would have the surplus to spend in other directions. We quote below a few specialities.

Many of our friends and customers having told us that *ounces* of seed were often far more than they required, we have lately, for the convenience of those with small gardens, put up packets at **2d.** and **3d.** for their convenience. We also offer nearly all the Hardy Annual Flowers in (liberal) **2d.** packets.

Fully Illustrated Catalogue Free on Application.

PEAS.

Gradus 1/-, Thos. Laxton 1/2, Reading Wonder 1/-, Triumph 8d., Prince of Wales 8d., Autocrat 9d., Prizewinner 1/-, Capt. Cuttle 1/-, Little Marvel 1/-, The Gladstone 1/-. ALL PER PINT.

All the best **BEETS** from **6d.** to **1/-** per oz.

„ **CABBAGES 6d.** to **8d.** per oz., **2d.** per pkt.

„ **LETTUCES** from **6d.** to **1/-** per oz., **2d.** and **3d.** per pkt.

Nearly all the best **ONIONS 6d.** to **1/8** per oz.

RADISHES 2d. to **3d.** per oz.

The BEST TOMATOES.

Best of All (Sutton), the best exhibition variety, **6d.** and **1/-** per packet.

Sunrise (Carter's), the heaviest cropper in cultivation: fruit perfect in shape and excellent in flavour, **3d.** and **6d.** per packet.

Smith's Ruby Cluster, an extremely free cropper; colour, shape and flavour excellent, **3d.** and **6d.** per packet.

Up-to-Date, very short jointed in habit, and extremely prolific. Fruit smooth, medium size, excellent quality, **3d.** and **6d.** per packet.

Kondine Red (Holmes), a wonderful cropper, **6d.** and **1/-** per packet.

ALL THE ABOVE ARE SAVED FROM SELECTED FRUITS.

CHOICE PRIMULAS.

We have a magnificent strain of these. The seed is saved in our own houses, with the utmost care. All seed is 1912 crop, and *certain* to grow if it has a fair chance. Large flowered varieties—**Brilliant King**, intense crimson; **Cannell's Pink**, gigantic flower, peach blossom colour; **Brilliant King**, deep velvety crimson; **Mrs. Robt. Cannell**, lovely white with deep red stems; **Pink Perfection**, pure light pink; **The Duchess**, white, with centre of rosy carmine and yellow eye; lovely **White Perfection**, fern leaved, the largest white. All these in separate packets, at **1/-** per packet. Also mixed, from above varieties, **1/-** per packet. **Stellata Mont Blanc**, and finest mixed, **1/-** per packet. The packets contain about 120 seeds.

A Fine Selection of Seed Potatoes—Scotch Grown.

J. R. PEARSON & SONS, "THE NURSERIES,"

LOWDHAM, NOTTS.

Established 1782.

BUSH APPLE TREES.

One of the most interesting features of the kitchen garden is a well-managed collection of bush apple trees, but if they are not properly looked after they are nothing more than an eye-sore. In travelling about the country I have seen a good many garden fruit trees, some in fine order, but the majority showing incorrect treatment in various forms. Very frequently the present gardener is in no way responsible for the neglect, because it may be that the trees were allowed to grow out of hand for years before he saw them. One of the most thankless tasks that can fall to the lot of a gardener is that of having to attempt to bring back to shape a number of wayward bush trees. If they are well-established in a good strong soil, a few seasons of unpruned liberty, above and below, will absolutely ruin them from the point of view of form. The careful, methodical grower who takes them over at this juncture feels his helplessness; he knows he has come too late. He cannot cut the branches back to the last pruning place on each limb, because such procedure would pitifully mutilate the branches, and remove a goodly portion of bearing wood into the bargain.

The only practical course open to the grower, in such circumstances, is to commence pruning again at the current year's wood, and gradually to thin out the head by cutting overcrowding branches away altogether. If there is much of this to do, let it be extended over several seasons. But even if the best is made of such trees, what do they look like? Instead of nice dwarf specimens, with a number of straight, definite, well-spurred branches set around a common centre, we have lanky, over-grown things, with many a foot of branch growth wholly devoid of spurs. Subsequent root and branch pruning will set them on the right track again, but, unfortunately, they must always carry the very obvious mark of some one's neglect, which is so irritating to those who are keen on shape and good methods generally.

Quite independent of all this, I think that many people who have good ideas on fruit growing allow their garden trees too much latitude. A system of pruning is now largely advocated by horticultural instructor and others which might more correctly be termed thinning. Under the hand of an expert this thinning process in the place of more severe pruning may be all very well, but the average man who attempts it will usually have his trees too straggling and encumbered with thickets of small growths. Where there is ample room, as in an orchard, by all means let us have fruit trees with large, spreading, natural heads, but I contend that the kitchen garden is no place in which to develop the practice. The space for garden trees is always strictly limited. They must not encroach upon vegetable quarters by root or branch, neither should they extend over the paths. The height must also be regulated within reasonable limits.

A bush tree dealt with under the light pruning system is unconformable to my ideal in several ways. In the first place, it grows too tall, thus overshadowing more vegetable ground than is justifiable; its diameter is too great, and its roots extend too far into adjacent soil. In a word, the system leans more closely to orchard culture than is compatible with garden ideals. I am acquainted with catalogues which recommend the planting of bush trees six feet apart. Suppose a novice acted on this advice, and then attempted to cultivate on the light-pruning principle. He would have a pretty tangle in a few years. I am aware that to plant six feet asunder is cutting it rather fine, but eight and ten feet are common distances, and, in no case, should it be necessary to exceed twelve feet. To keep trees within these limits, it is by far the best plan to run up a number of straight branches in open formation around the centre, and to prune them in exactly like so many cordons. Such specimens are neat and formal as garden subjects should be, and the fruit they yield is of the very best show quality. Of course, the weight of the produce is less than the yield from the semi-natural types, but, after all, a dwarf tree will bear heavily in proportion to its capacity. If we want a large quantity of fruit it is best to plant orchards or special quarters where we may legitimately practice the extension system of pruning, but such methods are out of place in an ordinary kitchen garden.

I have heard it said that close spur-pruning and the occasional root-pruning entailed are conducive to short life in a tree, but some years of close observation have convinced me that such is not the case.

The varieties in the list given herewith do well as bush trees, the fruits being excellent both for exhibition and culinary purposes.

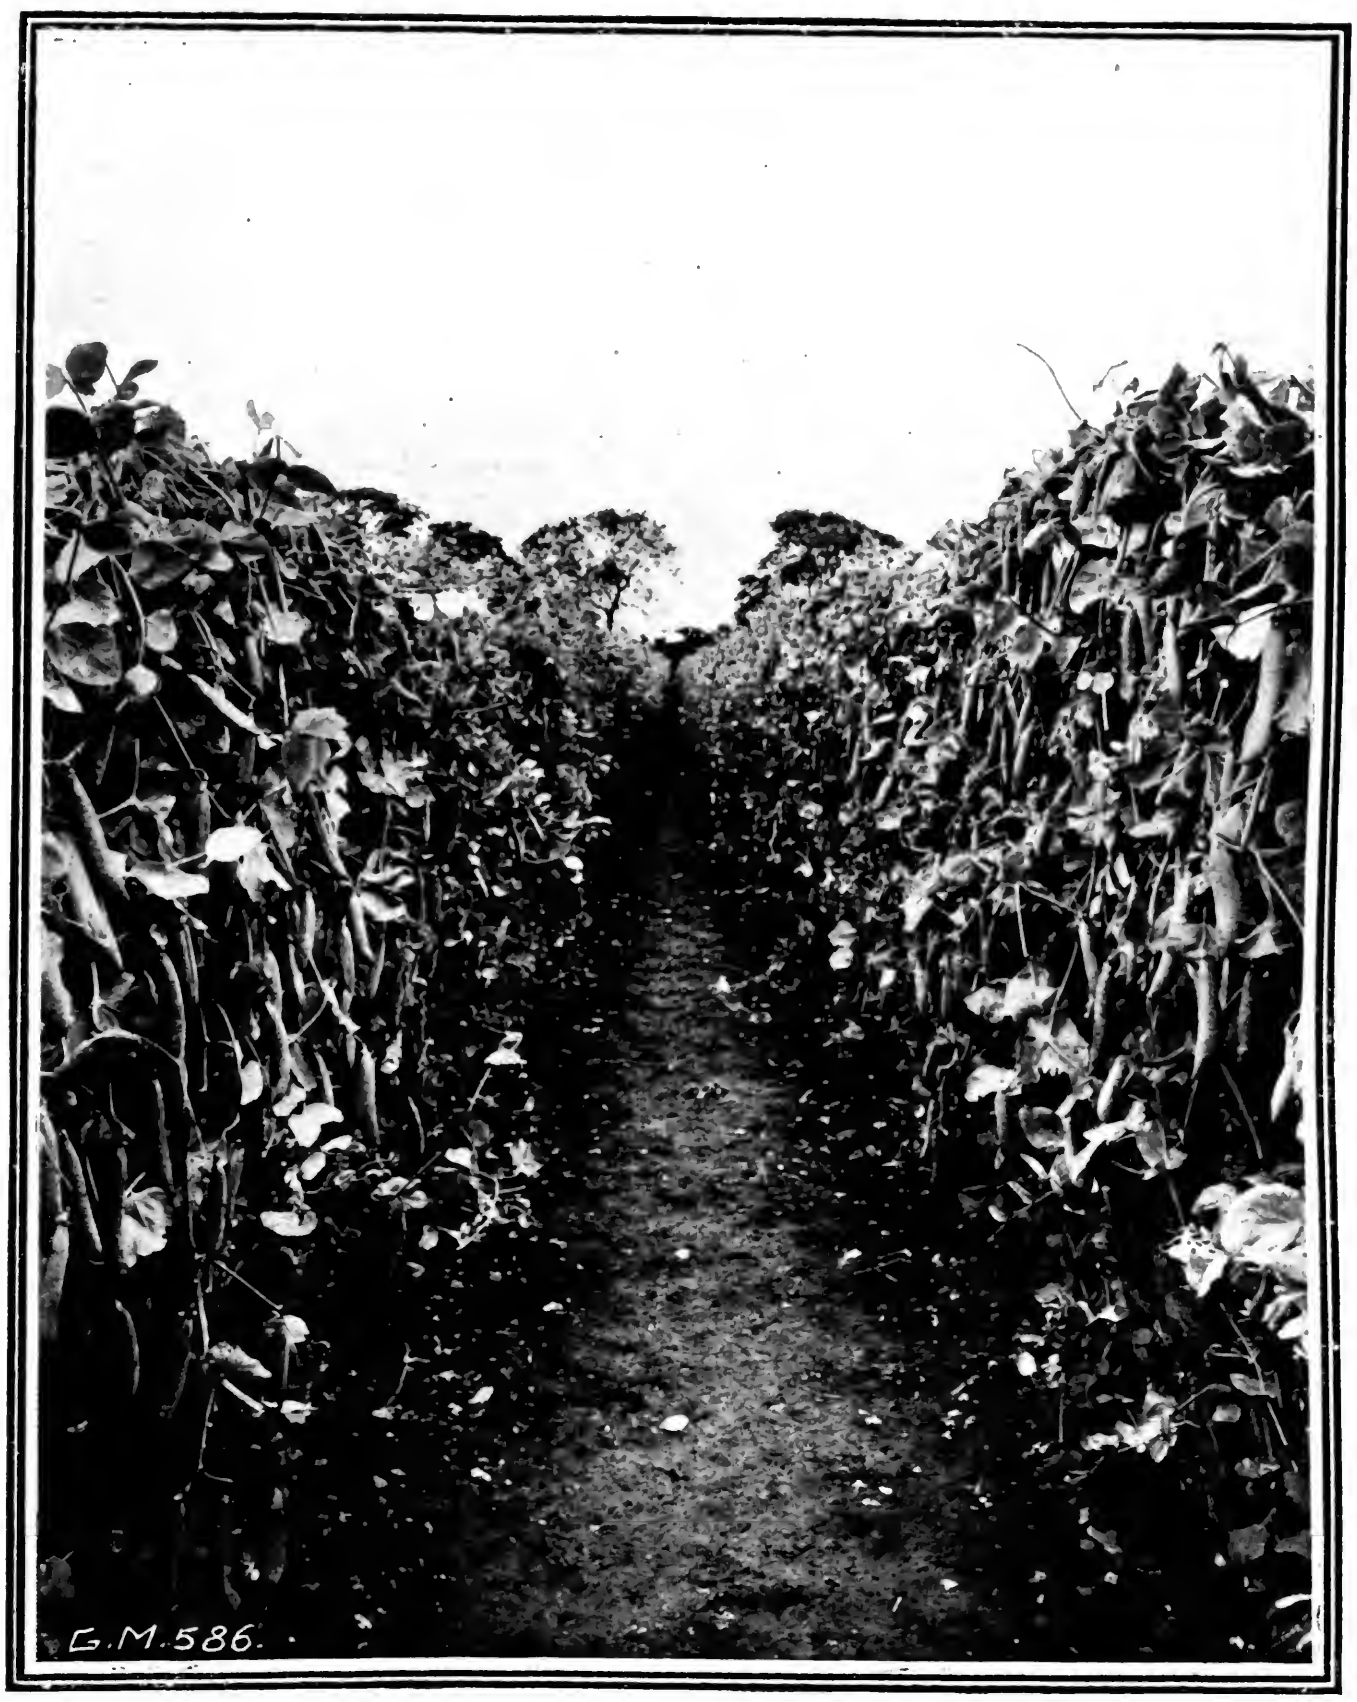
Culinary.—Peasgood's Nonsuch, Mère de Ménage, Lady Henniker, Stone's (Loddington Seedling), Bismarck, Sandringham, Lord Derby, Newton Wonder, and Lane's Prince Albert.

Dessert.—King of the Pippins, Adams' Pearmain, Allington Pippin, Beauty of Bath, James Grieve, Scarlet Nonpareil, Cox's Orange Pippin, King's Acre Pippin, Scarlet Pearmain, and Christmas Pearmain.

Ilmington. J. E. SIMMS.

NEW CULINARY PEA, BELL'S PREMIER.

For a number of years the Scottish firm of Messrs. Bell and Bieberstedt, of Leith, have paid particular attention to culinary peas, and the several varieties they have raised are all of first-rate constitution, free croppers, and of fine flavour. This season they are introducing two varieties that are altogether excellent and thoroughly well worth a trial, both in private and market gardens. Warriston Wonder is perhaps the heavier cropper of the two, but Bell's Premier is very little behind it in this particular, and it is of especially fine appearance. The pods are freely borne in pairs and usually ten peas in a pod. Bell's Premier is a second early pea, grows about 5½ft. high, and is the result of carefully selecting the best types from a cross between Gradus and The Bell. We have seen the varieties growing, and can testify to their excellence.



NEW CULINARY PEA BELL'S PREMIER.

Raised by Messrs. Bell and Bieberstedt, Leith, N.B.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

ARTIFICIAL HEAT.—A common mistake in the erection of glass structures both for fruit and plant growing purposes, lies in the neglect to provide sufficient hot-water pipes and boiler power to maintain the desired temperature without having to make the pipes excessively hot during periods of unfavourable outside conditions. Where sufficient piping is provided the temperature is naturally more readily and evenly maintained than is possible with an insufficiency of piping. Those who have these difficulties should endeavour to have every defect rectified. A great deal may be done to minimise excessive fire-heat by covering the roof of the house with a few archangel mats, waterproof covering, or even old blinds hung along the side lights and the lower portion of the roof. Where lath roller blinds are fitted to the roof, these may be let down on frosty or windy nights, and will make at least 7 to 10 degrees' difference to the inside temperature of the house. There is one thing one must be careful about in the use of lath roller blinds, and that is not to leave them down when there is a prospect of snow. Any great weight of snow is liable to break the blinds where they are jointed, and also twists them so much out of shape that they may be rendered useless for protection from sun afterwards.

ATMOSPHERIC CONDITIONS.—During the past fortnight we have been suffering from the effects of a snowy blizard, which has been followed with bitterly cold east winds and very little light. With so much fire-heat necessary, more than ordinary care has been required to keep the atmosphere in a condition to save the plants from any ill-effects. Damping the floors, staging, and surfaces below the hot-water pipes has been done as soon as the temperature commenced to rise in the morning; discretion has then had to be exercised respecting a second damping. Some portions of a house invariably become dry under ordinary conditions, and there need be no second thought over these spots, as the humidity rising from them when damped will have a tendency to equalise the moisture throughout the structures.

VENTILATION, or the admittance of fresh air to the houses is always desirable, but ventilation may easily be overdone just now. Whenever the outside conditions are favourable, air may be admitted either by the top or lower ventilators, but at no time during winter should the top and lower ventilators be opened simultaneously. It is always safest to use the bottom ventilators on the leeward side of the house, unless there is a good system of roof ventilation, for a very little aperture in the roof suffices for all purposes of ventilation at this season.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

AMARYLLIS (HIPPEASTRUM).—Bulbs intended for flowering in March and April should forthwith be removed from their resting quarters and receive a top-dressing or repotting as is considered necessary. Those selected for top-dressing should receive a thorough soaking in tepid water, and be allowed to drain, afterwards removing, with the aid of a pointed stick, as much of the surface soil as possible without damage to the roots, and adding new compost carefully made firm. Where repotting is necessary, thoroughly soak and carefully wash away all the old soil from the roots, afterwards potting firmly in well-drained pots of the same size, or, if necessary, a little larger. If the soil is in good condition no water will be required for some time, and must be given sparingly until the roots are quite active. A suitable compost is made up of loam two parts and leaf-mould one part, with a little mortar rubble and dried cow manure added.

GLOXINIAS.—A second batch may now be started into growth. Select those corms showing signs of starting, and after carefully removing the old soil, place them in pans containing sifted leaf-mould. In the humid atmosphere of the stove they will soon start sufficiently to be potted. Either 60 or 54-sized pots may be used with the view to shifting on later, or they may at once be put into their flowering pots, when 32's will be most suitable. In this case greater care will be required in watering or the soil will become sour. A suitable compost consists of two parts fibrous loam, one of peat, and one of leaf-mould, with a little sand and burnt earth.

CALADIUMS.—The remainder of these should be potted up, and started as early as possible, otherwise losses may occur. A compost similar to that used for gloxinias will be suitable; use as small pots as possible, and plunge in a hotbed. When nicely growing they may be transferred to larger pots.

ALLAMANDAS.—Where grown as trained specimens in pots allamandas, having completed their season of rest, should have their growths cut back to one or two buds, and if dry receive a watering. The free application of the syringe will soon induce them to break freely, when they may be turned out of their pots, the ball being carefully reduced, and the plants repotted. Good drainage is essential, and to ensure firm, short-jointed growth; there must be firm potting. Allamandas enjoy good fibrous loam to which has been added sufficient charcoal, mortar rubble, and sand to maintain porosity; a little bone-meal added will also be found beneficial.

PROPAGATION should be pushed on as far as possible. Cuttings of acalyphas, pandanus, Panax Victoriæ, and Dracæna Sanderiana will be found to root readily at this season.—H. PRIME, Hatfield House Gardens.

FRUITS UNDER GLASS.

POT VINES.—One-year-old vines, cut down to the lowest bud last month, will have been kept dry in a cool house; they may now be placed in a gentle heat, and gradually moistened to excite growth before being shaken out and repotted. Prevention being better than cure, a dressing of styptic should be applied to prevent bleeding, and a second dressing in some cases is advisable. When the buds have grown out from one to two inches, the strongest and most promising plants should be selected and potted. Meantime 11in. pots and compost should be got ready for use, especially the latter, as all composts in which bone-meal and other concentrated stimulants form a part are greatly improved by laying two or three weeks in a warm potting-shed or early vinery. Sound turfy loam, with lime rubble and a little bone-meal, must form the staple compost; a few handfuls of an approved vine manure may be added according to the quality of the loam. A little warm water may be given to settle the soil after potting; otherwise, when plunged in a steady bottom-heat of 75 degrees, the daily syringing will keep the vines quite moist enough until fresh roots are formed. Remove the weakest shoot where two have started; and put a light stake to the strongest to prevent accidents. Pure tepid water will suffice for a time, and good feeding later with liquid stimulants.

PEACHES.—The earliest pot and permanent trees will be swelling their fruits, and must be kept well syringed with tepid water twice daily in fine weather, and once only when cold and cloudy. As no one waters peaches during the flowering stage, a liberal supply at a temperature of 68 to 70 degrees should be given to inside borders as soon as the fruits attain the size of peas. Disbudding must be regulated by the vigour of the trees, young shoots may be removed from strong-growing trees with a liberal hand, but not so as to produce a check.

SUCCESSION HOUSES started now and the beginning of the year must be kept well supplied with atmospheric moisture, not so much by direct syringing as by damping the walls, paths, etc. A nice syringing once a day, or twice when bright, is beneficial, but keeping the trees constantly wet is detrimental. As the trees approach the flowering stage greenfly must be destroyed by one or two moderate fumigations, for if neglected it will soon mar the trees and possibly ruin the crop. A temperature of 45 to 50 degrees at night and 60 to 65 degrees by day, with little fire heat, will ensure strong perfect blooms, but to further ensure a good set the brush should be passed over the flowers daily. Later houses will set their fruits freely enough by keeping the pipes warm and the house carefully ventilated. As we cannot compel the sun to shine, we should endeavour to produce the next best conditions in our forcing houses, maintaining a brisk buoyant temperature by using warmth in the pipes and by the admission of plenty of fresh air on all favourable occasions.—F. JORDAN, Warter Priory Gardens.

THE FLOWER GARDEN.

CLIMBERS ON WALLS AND PERGOLAS, etc., which have not yet received attention with regard to thinning and tying, should be dealt with without further delay, as many of them are becoming quite active. Some of the large-flowering varieties of clematis have already made growths a few inches in length; these will require supporting to prevent them being broken off by rough winds or rain, to which they are liable at this stage. Ornamental vines which have not been pruned will, in many instances, bleed as this operation proceeds. Should this occur smear the cuts with shellac as a preventive.

WORKS OF CONSTRUCTION OR REMODELLING in the rock garden should be completed at an early date, if full advantage is to be taken of the coming season in establishing the various occupants, which are to be planted in any new positions. Preparations must be made for replanting any existing fissures or pockets which are becoming overgrown, or are in other ways unsatisfactory, by removing as much as possible of the old soil, and adding a compost most suited to the individual subjects. Rock plants intended for planting out that have had the protection of a cold pit or frame, should now be exposed as much as possible on all occasions, excepting during extremes of wet or cold, to ensure hardiness. The first opportunity during a spell of mild weather should be taken to transfer these to their permanent quarters in the rock garden. Timely planting is essential to success, as, naturally, alpine plants are most sensitive to early growth. The remainder of the rock garden should also be dealt with. All established plants must be looked over, removing any dead portions and rubbish which has accumulated. Move the surface soil between the plants in all accessible places with a small hand fork and pointed stick. Where any mossy growth is detected, it must be displaced and a top dressing of light sandy soil should afterwards be applied, which greatly benefits the plants, and also gives the whole a fresh and tidy appearance.

HOLLYHOCKS.—In districts where these cannot be successfully grown as perennials or biennials, owing to the prevalence of the disease which so often attacks them, it is advisable that they be treated as annuals, as the plants often then prove quite immune, and some very good results are obtained. Sow the seeds at once, thinly in pans, and place them in a brisk heat where they will soon germinate.—T. B. FIELD, Wych Cross Place Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE.—January 21.

Present: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair); Canon Fowler, Messrs. J. W. Odell, J. O'Brien, R. Hooper Pearson, A. Worsley, G. Wilson, A. W. Hill, G. Gordon, W. Hales, and F. J. Chittenden (hon. secretary).

DENDROBIUM FUSCESCENS. — Mr. O'Brien showed a specimen of this curious species with brown flowers from the Himalayan region. It is figured in Griffith's "Icon. Plant. Asiat.," t. cccix., and belongs to the section included by Lindley in his genus Sarcopodium (see Lindley's "Folia Orchidarum"), along with D. Cœlogyne, D. amplum, and D. rotundatum. Lindley considered the genus Sarcopodium intermediate between dendrobium and bulbophyllum, but later botanists have divided it, putting some of the species in bulbophyllum and some in dendrobium. It may be noted that the technical descriptions published of the species describe two orange spots on the column, but there are really three out of them quite low down.

APPLES WITH MANY OR NO PIPS.—Mr. Chittenden showed specimens of the apples, to which he had previously referred, having more than two seeds in the capillary cells. The variety Duchess's Favourite had, as a rule, in the past season four seeds in each cell, and the one case five had been found. This is remarkable, as the number in the wild types is practically constantly two, and that has been used as a basis of separation between the genera Pyrus and Cydonia. Like many other points of distinction between species and even genera, this would appear not to be absolute. He also showed specimens of an apple sent him by Mr. P. C. M. Veitch, of Exeter, called "No-Pip," which was reputed to form no seeds, although the apple was perfectly developed Those exhibited had only the merest rudiments of seeds, apparently no larger than the ovules had been.

GALLS ON POLYPODIUM SP. FROM THE GOLD COAST—Mr. W. H. Patterson sent specimens of the fronds of a polypodium galled along the edges of the pinnæ, and somewhat crested through the attacks of a species of Eriophyes. Mites belonging to this genus are well known as exciting the development of galls on all sorts of plants, and one, E. pteridis, and another, unnamed, are described as causing galls on the margins of fronds of Pteris aquilina in South Europe. Mr. Patterson finds the mite to spread but slowly among ferns at Aburi.

EARLY-FLOWERING ASH.—Mr. E. E. Turner sent from Coggeshall an example of an early-flowering species of Ash which had been identified as Fraxinus angustifolia. It always flowers in January, and is conspicuous by reason of the bright colouring of the flowers. Dr. Henry believes this to be the very rare variety holotricha.

Gardeners' Royal Benevolent Institution.

Punctual to the minute, the annual meeting of this charity was opened at Simpson's Restaurant, Strand, W.C., at 2.45 p.m. on Thursday, January 23. Sir Harry J. Veitch presided, and those present included: Messrs. A. W. Sutton, J. Hudson, D. Macdonald, R. H. Pearson, A. W. Paul, G. Caselton, G. Monro, L. Castle, O. Thomas, R. Cuthbert, P. Veitch, R. Ballantine, J. Rochford, W. Iceton, etc.

The minutes having been read and other formalities disposed of, the Secretary, Mr. G. J. Ingram, read the report and balance-sheet for the year 1912:

ANNUAL REPORT.

For seventy-four years the Institution has maintained the work for which it was founded with increasing benefit year by year to those deserving applicants who have been eligible for its assistance in their necessity and distress. No less a sum than £142,000 has been disbursed in relief since its foundation, and in the last year a sum of £4,413 was expended in affording permanent assistance alone, being £67 more than in any other year in the history of the Institution.

At the beginning of 1912, 252 persons—men and widows—were in receipt of life annuities of £20 and £16 a year respectively. Of their number 22 have died during the year—12 men and 10 women. Four of the men left widows, whose circumstances and needs being such as to render them eligible to succeed to the widow's allowance, were at once placed on the funds in succession to their late husbands, and without election under Rule 3, 13. Thus at the close of the year there were 234 annuitants on the funds. And to this number it is proposed to add by election this day 20 candidates from an approved list of 67 applicants—which will increase the list of beneficiaries to 254, being the largest number there will ever have been on the funds of the Institution. This further liability necessarily entails some anxiety, especially at a time when the charitable public are met with additional claims on their benevolence, but the committee feel their subscribers will justify this liberal action, and not let the Institution suffer in any way.

It is gratifying to the committee to be able to again report that the Victorian Era Fund and the Good Samaritan Fund have rendered invaluable services in helping applicants in distressed and necessitous circumstances.

Sincere thanks are also given to W. A. Bilney, Esq., J.P., the honorary solicitor, for legal services, and to Messrs. Thos. Manning, J. Willard, and Bert J. Monro, the auditors.

The committee have also again to acknowledge the kindness of the "George Monro, Lim." Concert Committee for devoting a share of the proceeds from their well-known and successful annual concert for the benefit of the funds.

The several auxiliaries have been a source of invaluable help during the past year, and have been well maintained, special and hearty thanks are tendered to the following honorary officers of the Auxiliaries for their services and kindly interest which is so much appreciated: Bristol and Bath—Col. H. Cary Batten (pres.), Mr. Geo. Harris (hon. sec.); Worcester—Rt. Hon. Earl Beauchamp, K.C.M.G. (pres.), John White, Esq. (treas.), and Mr. Percy G. White (hon. sec.); Devon and Exeter—Mr. W. Mackay (treas.), Mr. W. Mackay (hon. sec.); Wolverhampton—C. T. Mander, Esq., J.P. (pres.), Mr. Geo. Bradley (treas.), Mr. Geo. Bradley (hon. sec.); Berkshire, Reading and District—Mrs. Rowland Sperling (pres.), Arthur W. Sutton, Esq., J.P., V.M.H. (treas.), Mr. L. Castle (hon. sec.); and Liverpool Auxiliary—The Right Hon. the Early of Derby, K.G. (pres.), Mr. A. J. Crippen (treas.), and Mr. R. G. Waterman (hon. sec.).

The committee are also grateful to Messrs. Sherwood, Sutton, and Monro, who gave special contributions for unsuccessful candidates, which proved so beneficial to the recipients; they would also express their best thanks to Mr. N. N. Sherwood for his kind "Sherwood Commemoration Gift" of £500, which will be invested and form a fund to create a perpetual annuity of £20.

The committee are very glad to be able to acknowledge the distinction of knighthood bestowed upon their treasurer and chairman, and to recognise the generous donation of three hundred guineas to the funds from Sir Harry and Lady Veitch, "in recognition of the honours conferred upon horticulture."

The committee have to tender their cordial thanks to the directors of the recent great and successful Royal International Horticultural Exhibition for their kindness in voting two-thirds of the balance of the profits remaining, after all liabilities have been discharged, to the Institution. It is hoped that the funds will be considerably augmented from this source.

In concluding this brief summary of the year's work, the committee very earnestly commend this national horticultural charity—the only one of its kind in the United Kingdom to the generous consideration of all lovers of gardens and gardening, the purest of all human pleasures, for a larger measure of support to enable the Institution to extend a helping hand to those toilers in their distress and need who have given of their best for the pleasures and necessities of others.

The Chairman moved the adoption of the report and balance-sheet, and in doing so referred to the many losses the society had sustained by death during the year, and made special reference to Mr. Tillman and Mr. Garaway, who in the past had worked so well for the institution. Sir Harry urged that these losses should induce members and friends to work all the harder. Besides the amounts distributed in pensions, forty-two applicants were assisted by the Victorian Era Fund, and forty-one by the Good Samaritan Fund, making a total of 335 assisted in various ways by the institution. The Chairman made special refrence to Mr. N. N. Sherwood's generous gift of £500 to be invested, and said that Mr. Sherwood wished to nominate the first beneficiare. A goodly sum was anticipated from the Royal International Horticultural Exhibition, and Sir Harry

suggested that an extra pensioner might be elected in view of this expected gift. Kindly reference was made to the generous help received from Sir J. Colman, Bart., and to the promise Mr. Leopold de Rothschild had given to preside at the annual festival dinner on June 25 next. The work of the Auxiliaries was reviewed, and Sir Harry expressed a sincere wish that gardeners throughout the country might render more assistance than, as a body, they do at present, in carrying on the work of the Charity. He pointed out that there were five candidates coming up that day for election who had come up five successive years.

The motion was duly seconded, and carried without comment.

Mr. Arthur W. Sutton very pleasingly moved the thanks of members to Sir Harry J. Veitch, and his re-election to the office of treasurer. Mr. Ballantine seconded this, and it was very enthusiastically carried. Sir Harry returned thanks, and said this was his 27th year of office. On the motion of Mr. George Monro and Sir Harry J. Veitch Mr. G. J. Ingram was very heartily re-elected secretary, and his services were eulogised.

Mr. L. Castle moved the re-election of the retiring members of the committee, and the election of Mr. Martin Nash; this was seconded by Mr. Iceton, and carried.

Messrs. T. Manning, J. Willard, and B. J. Monro were re-elected auditors on the motion of Mr. Macdonald and Mr. P. Veitch. Arbitrators were also re-elected on the motion of Mr. Cuthbert and Mr. Rochford. Messrs. Bert J. Monro and Mr. J. White were appointed scrutineers, and the meeting was then adjourned until the declaration of the poll.

The poll was declared about 4.30. There were sixty-seven candidates, and those elected were: D. G. Chisholm (3,450), E. Morley (3,417), R. Stevens (3,394), Frances Throssell (3,253), H. Barnes (3,220), J. Page (3,144), G. Forty (3,120), Mary Smith (3,107), E. Baxter (3,014), W. Baker (2,991), H. Wright (2,935), F. Tucker (2,896), H. Witt (2,877), Fanny Stocking (2,869), Harriett Evans (2,859), W. Birse (2,826), Annie Canham (2,779), Susan Bryan (2,778), and Th. James (2,755). Under the permissive rule Martha Batten (1,376), and D. Reed (2,584) were also put on; Mr. Sherwood's nominee was R. McCombie; the International pensioner was W. E. Gaiger (2,739); and, as Mr. A. W. Sutton kindly offered a pension of £20 to a very needy unsuccessful candidate, Wm. E. Hill (2,710) was elected. This made a total of 25 placed on the funds—a record for any one election.

On the motion of Mr. Jas. Hudson, seconded by Mr. D. MacDonald, a hearty vote of thanks was accorded Sir Harry Veitch for presiding, and to the scrutineers for their services.

At the close of the day's proceedings the subscribers and friends dined together under the genial presidency of Sir Harry J. Veitch. Speeches were brief. The Chairman proposed "Success to the Institution," and referred once more to the splendid work of the Auxiliaries, and to the fact that a record number of pensioners had been placed on the funds of the institution that day. He made a strong appeal for greater help from the general body of gardeners, so that the institution might do greater good in the future. An interesting record of the progress of the institution was given in brief by Sir Harry, who stated that £4,500 a year was now needed to provide for the pensioners on the funds. The Chairman's reference to a gift of £10 from Mr. George Monro for the most necessitous unelected candidate was received with applause.

Mr. W. A. Bilney proposed thanks to the committee for able services freely rendered and to this Mr. Jas. Hudson, V.M.H., responded. Mr. Edward Sherwood very ably proposed "Our Country Friends," and in doing so emphasised the excellent work done by the several Auxiliaries: Mr. Peter C. M. Veitch (Exeter), Mr. Percy G. White (Worcester), and Mr. L. Castle (Reading) responded. "The Chairman," proposed by Mr. George Monro, V.M.H., was enthusiastically accorded musical honours. Sir Harry suitably replied. Mr. Ingram's services were eulogised, and the toast of his health was most heartily received.

A good programme of music added greatly to the pleasantness of this evening gathering.

Liverpool Horticultural Association.

This society held its 34th annual meeting on Saturday of last week in the Common Hall, Hackin's Hey, Liverpool, Mr. W. Mercer occupying the chair.

The statement of accounts submitted showed subscriptions, £255 10s. 6d. (a loss of some ten pounds); cash taken at the door for the spring exhibition, £41 2s. 11d.; summer show, £40 10s. 7d.; autumn show, £64 16s. 8d.; and special prizes, £43 13s. 6d. On the expenditure side: prize money at spring show, £74 6s. 6d.; rose and carnation show, £42 7s.; autumn show, £110 ;total, £227 13s. 6d. Hire of Corn Exchange, judges, music, staging, etc., totalled £227. The balance in hand, January 1 1912, stood at £152 9s. 9d., and on December 31 at £107 8s. 8d., a loss on the year's working of £45 1s. 1d.

The following gentlemen were elected: Patron, the Right Hon. Earl of Derby; president, the Lord Mayor of Liverpool; hon. treasurer, Loo Thomson, Esq.; sub-treasurer, Mr. G. Blackmore; and secretary, Mr. Harold Sadler, 31, North John Street, Liverpool. A cordial vote of thanks was tendered to Mr. Mercer for presiding.

Southampton Horticultural Society.

The 51st annual meeting of this society was held, by permission of the Mayor, at the Municipal Offices on January 20.

In the absence of the Mayor, detained by professional duties, Mr. R. C. W. Dixon, one of the vice-presidents, presided over a fairly representative gathering.

The Council's annual report stated that the efforts made to celebrate the jubilee of the society had resulted in two of the finest shows ever held in the South of England. It also expressed the Council's grateful thanks to the National Rose Society for assisting to secure such a fine rose show, and to all those patrons who subscribed liberally to the prize funds, but it contains regrets that the general public took little interest in the event; the attendance at the great jubilee show was less than at the ordinary summer shows for several years past, with the result that the society completed the year with a deficit of over £50. The statement of accounts shows the following results: Receipts: Rose show, £172 6s. 1d.; Jubilee show, £426 0s. 10d.; autumn show, £115 15s. 3d.; general account, £158 10s. 3d.—total, £872 12s. 5d. Expenses: Rose show, £166 4s. 10d.; Jubilee show, £459 3s. 7d.; autumn show, £134 2s. 10d.; general account, £158 11s. 3d.; new material, £8 2s. 6d. total, £926 5s. Assets (cash), £9 17s. 2d.; liabilities to treasurer, £54 1s. 7d.

The adoption of the report was proposed by Mr. E. Kemp Toogood, who took the opportunity to state that the exigencies of business would prevent him from continuing the office of chairman of the council. The president, Lord Swaythling, and the vice-presidents having been re-elected, the Chairman conveyed to Mr. Toogood the warmest thanks of the members for the way in which he had conducted the business of the society during his three years of office, and then proposed the election of Mr. Herbert E. Molyneux as chairman of the council, eulogising that gentleman's services to horticulture and to the N.R.S. especially. The election was carried by acclamation, as was also the re-election of Mr. C. S. Fuidge as secretary, a position he has held since January, 1873. The election of six members to serve on the council, and other officers concluded the business. The dates finally fixed for this year's shows are: Rose show, June 25; carnation and summer show, July 15 and 16; autumn show, October 28 and 29.

Bournemouth Gardeners'.

JANUARY 21.

The last meeting of the winter session was held on the above date. The evening was devoted to "Questions and Discussion." The questions are written on slips of paper by the members and placed in a box, then the latter is handed round and each member draws out a slip bearing a written question which he is expected to answer. Some of the queries are quickly answered, others create a lively discussion, as other members are allowed to state their opinions on each subject as well as the one who is entitled to first answer the query. This method is very popular, and so several evenings are devoted to "Questions and Discussion during the year.

The following are a few of the queries put: "What are the best manures for cinerarias?" Nitrate of potash and phosphate of potash were greatly favoured, at the rate of half an ounce to the gallon of water, as stimulants. "How can canker on Marechal Niel rose be cured?" One answer to this question was, that if a mixture of fresh cow manure and clay was put on the cankered parts a cure would result. Another reply was, the free use of fir tree oil. "Is April the best time to plant pines?" From November to April was considered to be suitable, generally, but Pinus pinaster should not be planted until new shoots commence to grow. "Should basic slag and kainit be applied to lawns in the autumn, at the same time, or should basic slag be applied in the autumn and kainit in spring?" Although some authorities favour the former, the members were unanimously in favour of the latter. "Is it advisable to propagate Primula sinensis by mossing side shoots?" The answer was No;

THE
VERY LATEST
AND BEST IN
HAND PNEUMATIC SPRAYERS.

The "Four Oaks," acknowledged by all users to be far and away the best on the market.

No separate pump. Self contained. A great advance over those kinds with separate pump. Cannot get out of order. The easiest, handiest, and most economical sprayer for greenhouse and garden work and disinfecting.

The "FOUR OAKS" Streetley Pattern.

Capacity, 2 Quarts.
Working capacity, 6 Pints.

Prices:
In Copper - 25/-
In Steel - 17/6

The copper machine is recommended where price is not a great consideration. Is **lighter, cleaner, and will not rust.**

FOR PURITY.

Because they are home grown, perfectly matured, of proved and tested germination, and selected with the skill and knowledge of experts.

FOR SATISFACTION. See the following:—From Mr J. Wilson, The Gardens, Alma Lodge, Torrington, St. Clement: "During the past three years I have won 150 prizes for vegetables and flowers, most of which have been from the produce of your seeds."

From Geo. Cater, Esq., Goodrich: "I send you another order for your renowned vegetable seeds, as I am confident from experience that their equal cannot be obtained from any other seed firm in the universe—i.e., germination, quality, and productiveness. Since I was fortunate enough to deal with your respected firm, which I contend is invincible, I have not a single failure on record. I therefore with confidence enclose postal order for a further supply."

TO-DAY IS THE DAY OF OPPORTUNITY.

Therefore send at once for our Manual of Gardening for 1913, the best Seed Book of the season, beautifully illustrated, full of valuable information, and should be consulted by all who have gardens.

When answering Advertisements please mention "Gardeners' Magazine."

because those side shoots, so rooted, would rarely bear more than one small truss of flowers. "Which are the best six Zonal Pelargoniums for winter flowering?" Snowstorm, E. Bidwell, Dryden, Souvenir de Mirande, Zelia, and Gertrude Pearson were the varieties favoured. There were many other questions, all dealing with seasonable subjects.

Ferns and narcissus were shown in pots by Messrs. Pearce, Evans, and Heath, in the "Points" competition. These exhibits were the final ones in the year's competition, and the following members are the winners, namely: Mr. C. Pearce, 56½ points out of a possible 66; he wins the silver-gilt medal. Mr. G. H. Heath, 53½ points; he wins the framed water-colour painting presented by Miss Agnes Rooper (the painter). Mr. Evans, 46½ points, wins the unframed water-colour painting presented by Miss Rooper, and painted by that lady. Mr. Pavey (who has not been able to take part in the contest at the two last meetings owing to illness), 39½ points, wins the book presented by the assistant secretary, Mr. C. Nippard.

The Chairman, Mr. Heath, was heartily thanked at the close of a very interesting meeting.

Beckenham Horticultural Society.

"Orchid Culture" was the subject of the lecture given by Mr. J. Collier, Gatton Park Gardens, Reigate, at the recent meeting. The lecture was intended for gardeners in general rather than for those who specialise, it being Mr. Collier's contention that those who can grow chrysanthemums and carnations well, can also, if they give the same amount of care and attention, succeed with many classes of orchids, and thus make them even more popular than now. The lecturer spoke of the value of the hybrids now being raised, many of which have such fine and robust constitutions. A few plants which had been raised at Gatton Park, were shown and much admired; they included an Odontioda Bradshawi, carrying 50 flowers; Odontoglossum Queen of Gatton, and Cypripedium insigne Gatton Park variety.

Broughty Ferry Horticultural Association.

The first meeting for this session was held in the Y.M.C.A. Hall, Brook Street, on the evening of the 21st ult. The President, Mr. James Bethel, occupied the chair, and there was a large attendance of members. After duly thanking those present for again re-electing him and by some encouraging remarks referring to the ensuing session, the President introduced the lecturer, Mr. A. W Brown, of Messrs. Alexander and Brown, seedsmen, Perth, who had for his subject "A Trip to the Dutch Bulb Fields." In the course of an excellent lecture, Mr. Brown led his audience from the "Fair City" to Haarlem, and with the aid of lantern slides, prepared from his own photographs, gave much interesting, educative, and amusing information on the bulb farms and the city and town life of Holland.

Of the area devoted to bulb culture the lecturer had much that was both interesting and instructive to relate, while his pictures enhanced the value of these remarks, clearly showing the methods of cultivation and manner of preparing the bulbs for market and transportation. Many new, rare, and expensive flowers of the various types of narcissus and tulips were also shown on the screen and commented upon by the lecturer, who spoke very highly of the kindness and courtesy shown him on his trip.

A short discussion ensued, after which the lecturer was accorded a cordial vote of thanks.

The monthly prize was awarded to Mr. George Reid, Invertay Gardens, for six pots of cyclamen, seventeen months old; marvellous specimens in 5in. pots.

Other exhibits were a vase of chrysanthemum flowers from Mr. D. Keillor, Seaborne Gardens; and leeks and celery from Mr. James Slater, Panmure Villa.

Dumfries Gardeners' Association.

The second meeting of this association was held in St. George's Hall, Buccleuch Street, Dumfries, on January 25, when Mr. S. Arnott, chairman, presided over a large attendance of the members, and after the usual formal business, called upon the lecturer, Mr. Croall, to give his paper on "Shows and Showing." This subject is always interesting, but it was treated by Mr. Croall in a manner which gave it special pleasure to the members. The usual practical treatment was varied by many humorous points, drawn from the author's experiences, and he discussed such questions as that of finances; the securing of influential support; that of tents or halls for the show; staging; choice of judges; judging by the eye or points; and the various details which make for the success or failure of a flower show. The head of "showing" was also well dealt with, and here, again, Mr. Croall's remarks were of a useful nature. The paper received close attention, and a capital discussion followed, taken part in by a number of the members, the subject of judging by points receiving special notice on the initiative of one of the members. Mr. Croall was heartily thanked for his paper. Mr. J. Hutchison, Terregles, exhibited a very fine begonia of the Gloire de Lorraine type, called amabilis, grown in an excellent manner.

York Florists' Society.

Alderman Agar presided over a moderate attendance on the occasion of the annual meeting of this ancient society.

Mr. W. Clack, the secretary, presented the report of the committee, from which we make the following extract: The committee again regret to have to record that the past year has not been of a satisfactory character financially. The number of members who have paid their subscriptions during the year is 453, as against 503 last year, and, in order to increase the membership the committee earnestly desire the members to try and influence their friends to join the society. The total income and receipts from all sources, inclusive of the sum of £63 14s. 6d. received from guarantors and special donations from the committee, members, and other supporters of the society amount to £374 8s. 7d., and the expenditure £365 6s. 10d., leaving a balance in favour of the society of £9 1s. 9d. The receipts at the Chrysanthemum Show amounted to £100 6s. 8d. for the two days, as compared with £157 8s. for the three days last year.

Mr. J. J. Hunt was elected president for the current year, and the following were elected members of committee: Councillor E. Allen, Messrs. J. W. Brocklebank, J. W. Clarke, E. Hagyard, J. W. Hodgson, H. S. Jubb, R. Keightley, J. Key, S. P. Kirkby, R. McIntosh, M. Murchison T. Parkin, S. Pickering, F. Raney, W. Todd, and J. Winn.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

ANSWERS TO CORRESPONDENTS.

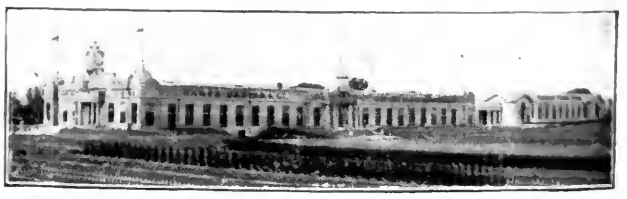
Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

AZALEA LEAVES FALLING.—A. W. B. Hounslow: Just at the time when the foliage of my azaleas should be forming a background to the coming flowers, they are falling off wholesale, owing, apparently, to a disease on the leaves themselves. I enclose a few leaves from the double white Niobe, which has suffered most, and I should be glad if you could tell me the nature of the disease, what steps can be taken for its prevention in future, and what can be done to cure it. I take considerable care in watering and syringing the plants, and at this season they receive occasional doses of liquid manure.—Insect pests, the results of dry atmospheric conditions, are largely responsible for the falling leaves. We found both thrips and red spider on the leaves, as we expected directly we saw the silvery-grey under-surfaces of the leaves sent. A dry atmosphere encourages these pests, hence the advantage of standing the plants on a good base of ashes which will hold moisture and



NEWS FROM HEADQUARTERS.

Throughout the entire year there is possibly no vegetable which creates such entire satisfaction as the first dish of Green Peas. Coming at a time when, for months past, the main supplies for culinary purposes have been a succession of those kinds familiarly known as "greens," the deliciously succulent Peas are very welcome. In company with a toothsome duckling, they form an addition to the menu which runs the traditional roast beef very close for first place in English gastronomy.

Sow two or three rows out of doors early in February if you have a very warm border, or should your garden be rather bleak, sow a few boxes in your most airy greenhouse, taking care not to coddle the plants, and plant out during April.

With only a moderate amount of care you will have the satisfaction of picking delicious peas quite early in the season, the flavour of which will be quite in advance of those forced under glass.

Carters' Early Morn, Early Duke, and Little Marvel are splendid kinds for this method of culture, and can be depended upon to give satisfactory results with a minimum of attention.

Send for our catalogue, or give us a list of your requirements, and we will gladly give any information you require.

Being our business it is no trouble to us to answer questions concerning the most suitable kinds for you to grow.

When answering Advertisements please mention "Gardeners' Magazine."

yet not keep very wet. The leaves are well formed, consequently we may presume that in spring and summer the cultural details followed were successful, and that the trouble has come since the azaleas were housed. Lay the plants on their sides and syringe them with a nicotine preparation; it will be necessary to syringe them with an insecticide two or three times at intervals of about four days. Well-grown plants of Indian azaleas do not need liquid manure, though, when well rooted, an occasional watering with clear soot water is beneficial. You may have over-dosed the plants, and this in conjunction with the weakening effects of the thrips, would readily cause the leaves to fall.

POROUS FANCY JARS FOR FERNS.—A. W. B., Hounslow: I am anxious to find out where I can procure those porous jars sometimes used to grow maidenhair ferns in. They are indifferently called Egyptian or Maltese jars.—The horticultural sundriesmen who advertise in our columns will be able to supply you with these jars.

YARROW IN LAWNS.—J. B., Kettering: We have a lawn full of yarrow or wild achillea, and I should be very glad if you would give me any advice as to the best means of removing this weed without taking up the turf. I am much afraid we cannot do much good, as the yarrow is so abundant and so deep rooted.—Probably, your best plan would be to remove the turf and lay down new clean turves or sow the lawn with the best lawn grass seed. Later on, if you decide not to returf or sow, use lawn sand, but we may say at once that if the lawn is now practically composed of yarrow then the lawn sand will leave the area very bare. All things considered, your best plan would be to remove the present turf, thoroughly dig the site, add new soil to make up the levels, and prepare for sowing.

APPLE FOR NAME.—D., Uckfield: I enclose six fruits of an apple, and should be glad if you can tell me the name of the variety. I know nothing like it, but, as the tree appears to be about sixty years of age, it may very likely be a local and unnamed seedling. It is a splendid apple, and keeps finely without any special care.—The apple is in excellent condition, and should be perpetuated. We do not recognise it. Why not put some grafts on two or three young trees that you can spare for the purpose, and then see what the variety is capable of?

PELARGONIUMS FOR EXHIBITION.—G. B., Colwyn: Could you give me particulars respecting the treatment of pelargoniums for exhibition?—Yes, and we shall be pleased to do so, but we do not gather whether show or fancy or zonal pelargoniums are under consideration; what period of the year the exhibition you have in view is being held, or whether good, useful plants or large specimens are to be grown. If you have some sturdy plants of zonal varieties, struck early last autumn and potted off singly, you may produce large plants by midsummer, if good feeding, due potting, pinching and tying are attended to, and a greenhouse or pit can be used for them. However, let us have further particulars of your intentions.

PROPAGATION OF PERPETUAL CARNATIONS.—Mr. G. Herbert Lawrence, Stratton, Godstone, Surrey, writes: As a regular reader of the GARDENERS' MAGAZINE, I hope you will allow me to cast some doubt upon Mr. Allwood's advice in your issue of January 18, given respecting the time to propagate perpetual carnations. Mr. Allwood states that, provided good cuttings are rooted in January, better plants are produced in twelve months than from those rooted in October and November. I agree with him up to a point, and that is January cuttings will produce the best flowers the following January and onwards, but I contend that if good flowers are required in November, the cuttings must be taken the preceding November. It takes fully twelve months' development, from the propagation period, to produce really good flowers. One nearly always reads in catalogues, where hints on carnation culture are given, that to obtain good blooms before Christmas cuttings should be taken in January. I maintain that this advice is erroneous and misleading, and my point is that one must not reckon on the full development of the plants, and blooms worth looking at under twelve months, therefore, if blooms are wanted in November and December, propagation should start in the corresponding months of the preceding year. However, perhaps, Mr. Allwood may have a further explanation to offer?

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

S. S., Johnston.—1, Berberis Hookeri; 2, Begonia manicata; 3, Helleborus orientalis.

O. W., Wokingham.—1, Saxifraga sancta; 2, Acantholimon glumaceum; 3, Veronica Hectori.

G. H., Kenilworth.—1, Anthericum variegatum; 2, Dieffenbachia amœna; 3, Phyllotænium Lindeni; 4, Calathea Sanderiana; 5, Selaginella cæspitosa.

D., Uckfield.—The fern is Polystichum aculeatum divisilobum; the bamboo is not in a good condition for naming, but it may possibly be Arundinaria castillonis.

W., Cheam.—1, Send when in flower; 2, Begonia Haageana; 3, probably Begonia argentea-guttata; 4, Maranta bicolor Massangeana; 5, Rhœo (or Tradescantia) discolor; 6, Carex brunnea.

FORTHCOMING ENGAGEMENTS.

MONDAY, February 3.—National Chrysanthemum Society's Annual Meeting at Carr's Restaurant, Strand, W.C., at 7 p.m.

TUESDAY, February 4.—Royal Horticultural Society; Committees meet at 12 o'clock; Lecture at 3 p.m. on "Plant Hunting in Bulgaria," by Mr. C. F. Ball; Scientific Committee at 4 o'clock.

Horticultural Club, Annual Meeting and Dinner at the Hotel Windsor, Victoria Street, Westminster.

THURSDAY, February 6.—Linnean Society.

FRIDAY, February 7.—Royal Gardeners' Orphan Fund, Annual Meeting and Election at Simpson's Restaurant, Strand, W.C., at 3 p.m.

MONDAY, February 10.—United Horticultural Benefit and Provident Society.

TUESDAY, February 11.—Royal Horticultural Society's Annual Meeting, at the Royal Horticultural Hall, at 2.30 p.m.

National Vegetable Society's Annual Meeting, at Royal Horticultural Hall.

WEDNESDAY, February 12.—Croydon Gardeners' Society, Annual Dinner at the Greyhound Hotel, Croydon, at 7.30 p.m.

FRIDAY, February 14.—Finchley Chrysanthemum Society's Annual Meeting.

MONDAY, February 17.—National Chrysanthemum Society; Floral Committee's Annual Dinner, Carr's Restaurant, W.C.

TUESDAY, February 18.—Royal Horticultural Society; Committees meet at 12 o'clock; Lecture at 3 p.m. on "Some Flowers of Eastern and Central Africa," by Miss Mason; Scientific Committee, at 4 o'clock.

WEDNESDAY, February 19.—North of England Horticultural Society's Annual Meeting and Exhibition at Leeds.

CATALOGUES RECEIVED.

JAMES CARTER AND CO., RAYNES PARK, S.W.—This catalogue is of unusual interest, because of its illustrations of the firm's new business premises and trial grounds, and the evidences they give of the great care taken to ensure seeds of the finest quality. There are nearly 300 pages, and not a dull one from beginning to end. Seeds and plants are listed, and there are numerous novelties for consideration in addition to old favourite varieties.

J. JEFFERIES AND SON, LIM., CIRENCESTER.—A carefully-arranged seed catalogue; flowers are a special feature, and collections of asters, grasses, stocks, sweet peas, etc., figure largely in the list.

The Thames Bank (Blackfriars) Iron Company, Lim.—Owing to the similarity of the name of this company and that of the Thames Iron Works and Shipbuilding Company, of Blackwall, confusion, we are informed, often arises in the public mind as to whether the two companies are not one and the same. This, however, is not the case, and we are desired to state that the Thames Bank (Blackfriars) Iron Company, Lim., are in no way connected with the Thames Iron Works and Shipbuilding Company.

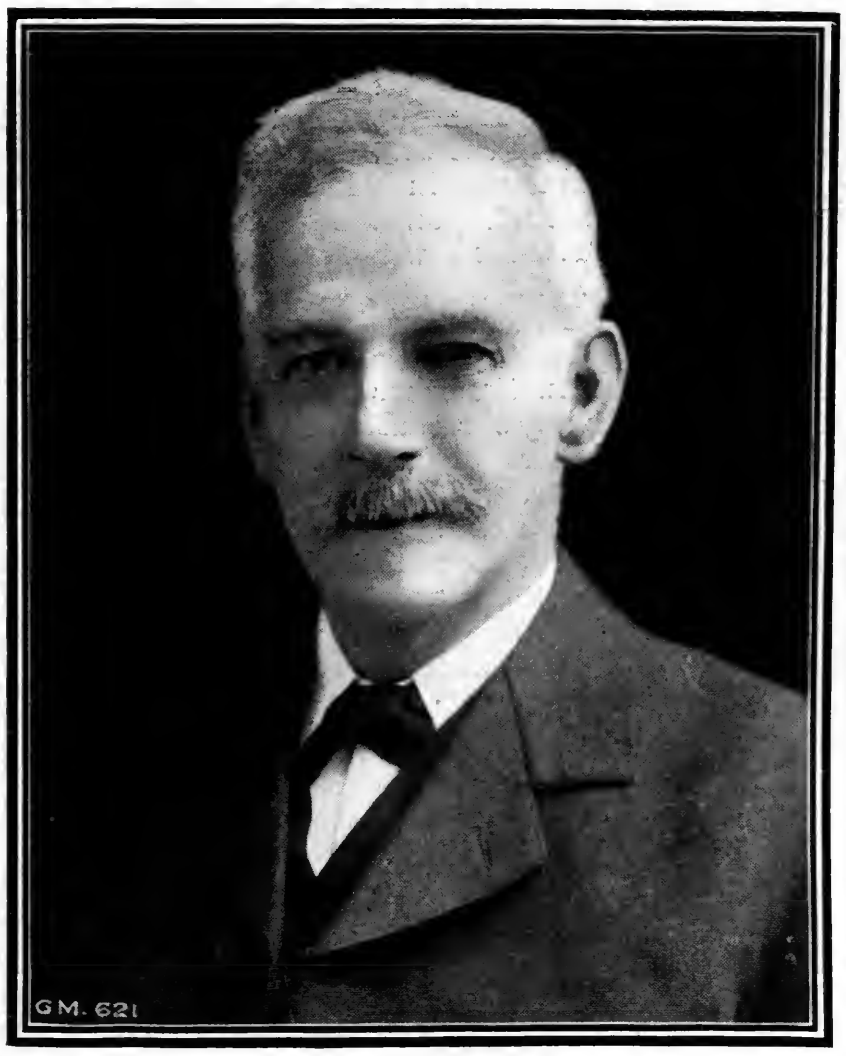
VOL. LVI.—No. 3,093. SATURDAY, FEBRUARY 8, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Progress of the Royal Horticultural Society.

Twenty-five years having elapsed since the Royal Horticultural Society vacated the gardens that it had so long occupied at South Kensington, and adopted a strictly horticultural policy, the report that will be presented by the Council to the fellows assembled in annual meeting on Tuesday next will have an importance that may be regarded as quite exceptional. Interesting as the society's annual reports have invariably been since the initiation of the present regime, the record for the past year is especially so because of the opportunity it affords of making an estimate of the society's progress, based on the results obtained during a well-defined and comparatively long period. It has been possible to obtain a very clear idea of the achievements of the society from the reports submitted to the Fellows from year to year, but a comparison of the results obtained in one year with those of the twelve months that have immediately preceded it fails to impress one in the same manner as does the institution of a comparison between the achievements of, say, 1888 and the past year. Then the society's fortunes were at so low an ebb, as a consequence of the mistakes of previous Councils, as to give rise to the gravest anxiety, and now the society is the largest, the most vigorous, and the most wealthy organisation associated with horticulture the world has ever seen. Twenty-five years is not so long a period for a society with comparatively few Fellows and a small income to increase its Fellowship to over 13,000, to establish an experimental garden on a large scale, and fully equipped in accordance with the most modern ideas, to found a School of Horticulture, to build itself an exhibition hall and offices at a cost exceeding £40,000, to invest upwards of £60,000, and, what is certainly not less, to obtain the confidence of horticulturists of all classes, not only in this country, but in all parts of the civilised world. Such achievements as these necessarily evince rare judgment and unremitting energy on the part of both members of Council and officers, and also unity in formulating and carrying out the various schemes of work. The representative character of the Council has, it may be assumed, contributed in no small degree to the success that has been achieved; and there can be no doubt that the few changes in the constitution of the Council have been a source of strength, inasmuch as they have rendered possible the continuance of the policy which has had such remarkable results. In the president and secretary there has been no change during the past twenty-five years, and fortunately so, for



MR. DAVID KING.

the occupants of these offices have evinced ability of an exceptionally high order in the discharge of their respective duties. Five years since Sir Trevor Lawrence was presented by the Fellows with his portrait as a mark of their appreciation, and at the present time it is thought by many of those closely associated with the Rev. W. Wilks in the society that the occasion should not be allowed to pass without some recognition of the splendid service he has rendered during this long period. As a consequence of this feeling a movement is on foot for the purpose of presenting him with a testimonial, and as the subscriptions are not to exceed £1 1s., a large number of Fellows and others will, it may be assumed, take advantage of the opportunity for showing their appreciation of his work. During the past year there was a considerable accession of new Fellows, and a substantial increase in the income. The total income was £27,201 17s. 3d., and of this amount the sum of £19,003 2s. was received as annual subscriptions, £2,549 18s. 6d. in dividends and interest, £961 3s. 5d. from admission to the shows and meetings, and £2,669 14s. 7d. from hall lettings. The amount received from the armissions to the exhibitions and meetings was smaller than usual, owing to there having been no Temple Show consequent on the holding of the Royal International Horticultural Exhibition, in which the society took a warm interest, and to the wet weather experienced on the occasion of the Holland House Show. The charges on the hall, including ground rent, water, gas, and electric light were £1,517 16s. 1d., the exhibitions and meetings involved an expenditure of £2,345 2s., the cost of the Wisley Gardens was £2,344 14s. 9d., and of the Laboratory at Wisley, £577. The balance on the year's work is £9,194 4s. 1d., or rather more than one-third of the income. Liberal contributions were made to the Lindley Library, which is now under the direct control and management of the Council, and a considerable number of rare works on horticulture were added, among them being Andrews' "Roses," Curtis's "Camellias," and Hooker's "Pomona Londinensis." It is, we observe, intended to publish the Journals kept by Robert Douglas of his travels on behalf of the society through North America in 1824 and the following years, and it is hoped that the MS. may be ready for the press during the current year. Those who are interested in the education of gardeners as a means of improving their status will learn with satisfaction that the Council have been successful in obtaining the power to establish an examination conducted by a Joint Committee of members, appointed by the Board of Agriculture and the Royal Horticultural Society, to determine the recipients of the diploma. This announcement should afford much satisfaction to those gardeners who desire to obtain such distinction as will show that they have full acquaintance with the practice and science of horticulture. The hope is expressed that a Degree in Horticulture may also be established by the University of London, and it well, in that case, be the aim of the Council to make the society's diploma work up towards the University degree.

Another important step onwards has been taken in the decision to establish a Parliamentary Committee, whose work it will be to advise the Council on all questions relating to legislation affecting horticulture. There will be two changes in the constitution of the Council, consequent on the retirement of the Hon. John Boscawen, owing to the great distance at which he resides from London rendering it difficult to attend the meetings with the necessary degree of regularity, and of Mr. William Marshall, who, acting under medical advice, is compelled to relinquish his seat on the Council. The vacancies thus created will be filled by the election of Mr. Arthur W. Sutton and Mr. C. G. A. Nix, both of whom are well known for their commanding ability and for their keen interest in all that relates to the advancement of horticulture.

Mr. David King, the new president of the Scottish Horticultural Association, of whom we give a portrait, is a well-known and much-esteemed member of the Edinburgh nursery and market garden trades, with which he has been closely identified for many years. Mr. King served his apprenticeship at Millfield, near Polmont, and afterwards he served in the gardens at Kinfauns Castle, Gartmore, and Brechin Castle. He commenced business on his own account at Osborne Nursery, Murrayfield, in 1874, and he has specialised in ferns, of which he grows immense quantities for market purposes. He was the first to introduce bowls filled with forced tulips and hyacinths into the Edinburgh flower and fruit market for Christmas decoration, about 35 years ago, and he does a large trade in these articles and in market plants generally. He also does a considerable amount of laying out of grounds, especially of the villa garden class. Previous to his election as President, Mr. King was convener of the Finance Committee of the Scottish Horticultural Association, and he is a member of Council of the Royal Caledonian Horticultural Society. He is also president of the Market Gardeners' Association, which position he has occupied for six years, and he is one of the co-opted members of the Scottish Chamber of Agriculture.

Conference on Dahlias.—The National Dahlia Society, in pursuance of the policy which was initiated three years since, and has proved so highly successful, has arranged to hold a conference this year. This conference will be held at Carr's Restaurant, 264, Strand, W.C., on Friday evening, February 14, commencing at 6.30 p.m. The president, Mr. George Gordon, V.M.H., will preside. The papers that will be read are as follows: "Exhibiting and Judging Dahlias," by Mr. W. C. Wyatt (Messrs. Keynes, Williams, and Co.), Salisbury; "The Future of the Dahlia," by Mr. F. G. Treseder (Messrs. W. Treseder, Lim.), Cardiff; and "Garden Dahlias," by Mr. A. J. Cobb, Duffryn Castle Gardens, Cardiff. All members are cordially invited to attend and join in the discussion which will follow the reading of each paper.

The Late Mr. Champion Jones' Pictures.—An exhibition of the late Mr. Champion Jones' pictures will be held at the Modern Gallery, 61, New Bond Street, W., from the 12th to the 25th inst. The exhibition will comprise water colours and oils of Vancouver, Holland, and England, many of the examples representing the artist at his best. The late Mr. Champion Jones, who was an exhibitor at the Royal Academy, was for many years the artist attached to the staff of the GARDENERS' MAGAZINE, and in that connection his finely-executed drawings of plants and flowers will be familiar to a very large body of our readers.

Damage to Golf Greens is the latest development of suffragist militancy, and if this is not so serious as the raid that has been made upon pillar boxes, it is sufficiently so to justify a strenuous endeavour to put a stop to it. On January 30 it was found that four golf courses in the Birmingham district had been seriously damaged. At King's Norton three greens were much injured, and on each of these the words "Votes for women" had been cut into the turf in large letters, and an acid had been poured into the ground, destroying the grass. At the Walmley course at Erdington, six or seven miles away, six of the greens were damaged. Here the words "Votes for women" were outlined in the grass, and fluid acid sprinkled about. At the Robin Hood (Hall Green) and Edgbaston courses much damage was also done.

Exhibition of Garden Dahlias.

An exhibition of dahlias especially adapted for beautifying the garden and decorative purposes generally will be held conjointly by the Royal Horticultural Society and the National Dahlia Society at the Horticultural Hall on September 23. Two competitive classes will be provided, one for displays of dahlias open to trade growers only, in which the premier award will be a challenge cup of the value of seventy-five guineas, presented by Reginald Cory, Esq., and the other for displays open only to amateurs, in which the Veitch Memorial Medal, presented by the Veitch Memorial Trustees, will be offered as the first prizes. In the first of the two classes the Royal Horticultural Society's medals will be awarded as the second and third prizes, and in the other class the National Dahlia Society's medals will be awarded in a similar manner. In addition R.H.S. medals will be awarded to collections of garden dahlias that have not been shown in the competitive classes, but are of sufficient merit to warrant an award. The awards will be made by judges appointed in equal numbers by the two societies.

Shrubs for Winter Effect.—Mr. George Bunyard, V.M.H., writes, from Maidstone: "An article in the GARDENERS' MAGAZINE of January 25 draws attention to some useful shrubs for winter effect. May I be allowed to extend the list by naming, among the red and brown stems, the forsythias, Raspberry Bath's Perfection, Salix Brityensis, Spiræa Watereri and weigelas. Then there are the green stems of Euonymus europæus, Erica codonodes, Kerria japonica, and Tamarix gallica. In white and grey we have the Silver Birch, Populus alba, and Salix cærulea, while of brighter hue is the bark of the weeping yellow-barked Babylonian willow."

Building in Regent's Park.—The Parks Committee of the London County Council have recommended the Council to pass the following resolution: "That the Council, realising with anxiety the effect of the building operations recently undertaken on Crown lands at Regent's Park, earnestly trusts that upon the expiration of the existing Crown leases the remaining grounds which are now in private possession will be dedicated to the use of the public for general recreation, and asks that effective steps may be taken to prevent at any future time the granting of any fresh leases of the lands in question." In their recommendation the committee direct attention to the fact that with regard to St. John's Lodge and St. Katharine's Lodge, proposals are under consideration for reletting the property until 1973, although the existing leases do not expire until 1916 and 1929 respectively. It therefore considered that no time should be lost in endeavouring to secure for the use of the general public, not only these particular enclosures, but also some of the other enclosures in the park as opportunities arise. Whatever may have been the condition of the surrounding districts when the original leases were granted, the committee consider that it will be generally admitted that, to meet the requirements of the present-day population, every effort should be made, not only to preserve intact such lands as have not been built upon, but also to have them thrown open as part of the park, thereby rendering it of greater utility and benefit to the general community.

Kew Gardeners' Social Gathering.—The sixteenth annual social of the gardeners of the Royal Gardens, Kew, was held at the Boat House last month. The party numbered about a hundred and forty, including a good muster of old Kewites. The programme contained twenty-four dances, and Mr. Symons was M.C. Between the dances songs were rendered by Miss Denny, Messrs. Gardner, Glover, Richli, Southgate, and James, and Mr. C. Harding recited "On Strike."

Wolverhampton Floral Fete.—This year will be the twenty-fifth anniversary of the floral fête which has obtained for Wolverhampton a prominent position among the great industrial centres in which horticulture receives special encouragement. In view of this fact, an endeavour will be made to render the exhibition to be held on July 8, 9, 10, additionally attractive. Among the new classes is one for a display of bedding plants arranged in the form of a flower garden, with flower beds, walks, pergolas, or roses, as the exhibitors may select. The superficial area of the space allotted for each garden will be 30ft. by 20ft. There will also be special classes for carnations and roses.

Improvements in Epping Forest.—According to the annual report of the Epping Forest Committee of the Corporation, they continued last year to improve the forest by removing superfluous and non-indigenous trees with the object of encouraging the growth of the best specimens of forest trees, and they had also opened up further glades so as to make the forest more accessible to the public. Adjoining the northern boundary of the forest there are three small unenclosed strips, and as the owner was about to enclose those strips, the committee purchased them with the object of retaining access from the road to the forest by the general public and the commoners' cattle. The expenditure on the forest last year was £7,016, towards which £2,964 was contributed by the Corporation.

The Guernsey Growers' Association are making strenuous endeavours to improve some of the methods of culture that find favour among the growers of garden produce in the island. They have arranged a series of lectures on the scientific and practical aspects of the cultivation of fruit, tomatoes, and flowers under glass. The association is desirous of extending the knowledge of the most successful methods among the members, in view of the competition of foreign growers in the English markets. While immense quantities of produce of high quality are exported by the Guernsey growers, considerable quantities reach our markets in a condition that shows there is, in the case of some of the producers room for considerable improvement.

THE MADWORTS.

The Madwort family includes some of the most attractive and useful of the spring and early summer-flowering plants. Most of them are of dwarf and neat habit, and, with few exceptions, are good perennials. To fully appreciate the beauty of the free-blooming A. saxatile it must be planted in a good-sized group, hence it is most valuable for the purpose of spring bedding. Single plants, however, growing in the joints of a wall, and hanging down over its face, are very effective and beautiful when in flower. The stronger kinds may be used with advantage planted in groups in the front rows of the herbaceous border, but the smaller-growing species are more at home in the rock garden on sunny ledges.

Generally speaking, all the Madworts will grow in any well-drained soil, and they may be considered as amongst the easiest of plants to raise from seed. Cuttings also afford a ready means of increase, and these may be made from the young shoots two to three inches in length in summer, as soon as they have made sufficient growth after flowering. It is necessary to insert them in sandy loam, and keep them in a close, shady place till they are rooted.

There are many small, dwarf-growing species that are very much alike in habit and in flower, and though they may be desirable, from a collector's point of view, a few of the more distinct kinds will suffice to provide a very attractive display. Some of the best are:

Alyssum alpestre.—This is somewhat prostrate in growth and is found growing on high exposed rocks in the Nicolaithal in Valais a canton of Switzerland. It has a shrubby base and is freely branching, with greyish leaves, and numerous corymbs of rich yellow flowers. This madwort is best adapted for a sunny corner in the rock garden, planted on a ledge or sloping stony bank.

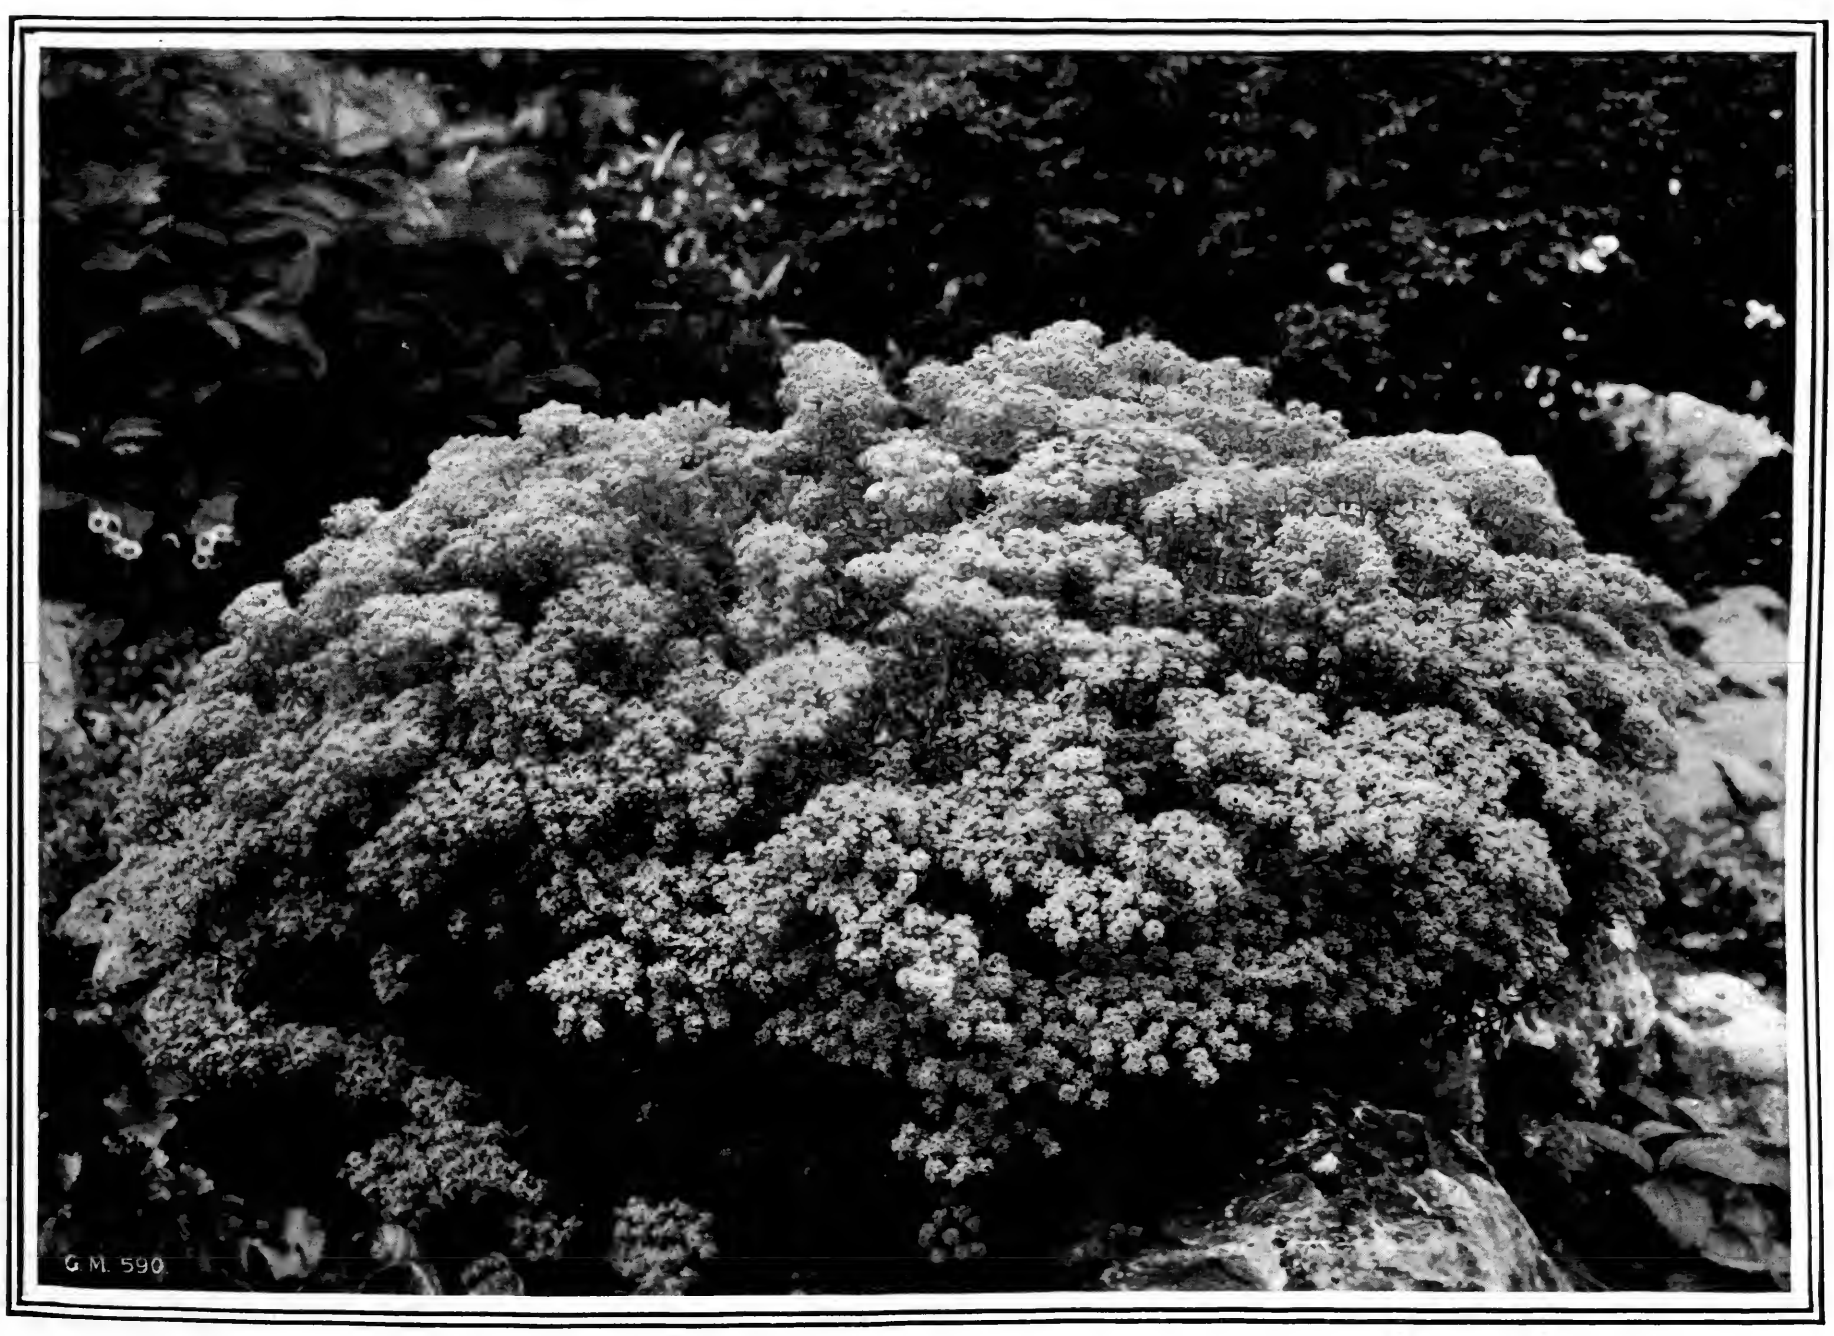
A. argenteum.—Some idea of the very effective appearance of this species may be gathered from the illustration. It makes a bold, bushy plant, from one foot to eighteen inches high, and often two feet or more through, with a shrubby base. The silvery-grey foliage is very attractive even when not surmounted by its corymbs of bright yellow flowers. Large isolated plants form an attractive feature in the rock garden when planted on prominent knolls, and as it is practically evergreen, provides a furnishing for the winter months.

A. saxatile.—Few plants are better known or more valued in the garden than this madwort. Its brilliant flowers, produced in a dense mass, and its dwarf habit of growth, render it particularly useful for the rock garden, or for planting in the crevices of old walls. Its earliness also makes it valuable for other spring decoration. As this species is naturally found growing on the open hills in Southern Europe, it should be planted in positions fully exposed to the sun. Bits of broken limestone or old mortar rubbish may with advantage be mixed with the soil when planting. The lemon-coloured variety, citrinum, is a charming companion for the above, with its masses of pale yellow flowers. It is of the same habit, and quite as hardy, and is very beautiful growing on the face of a wall. There is a dwarf form of this known as var. compactum, or Tom Thumb; it is compact in habit. The double-flowered variety is not so floriferous as the type, but the flowers are large, and rich yellow.

A. spinosum.—A South European species, which forms dense bushes of spiny, woody branches, clothed with small hoary leaves. Planted in the rock garden so that it may grow over a protecting stone, it will make a striking object, growing in a compact hummock about one foot high and two or three feet through. The flowers vary from white to pink, and they are produced freely throughout the summer months. Seeds are produced very freely, and seedlings come up in great numbers round about the old plants.

The best of the smaller species is the sweet-scented A. montanum, only an inch or high, with prostrate branches, hoary leaves, and rich yellow flowers. It is an excellent plant for a sunny bay in the rock garden, and should be planted in very gritty soil, otherwise it damps off in winter.

W. I.



ALYSSUM ARGENTEUM.

A bold-growing and highly attractive madwort, with silvery leaves and bright yellow flowers.

SOME CHOICE ALPINE FLOWERS.

Shortia uniflora grandiflora.

The wonderfully beautiful Shortia galacifolia has a rival of no mean pretensions in its own family, the lovely Shortia uniflora, charming everybody with its delightful foliage of green, passing to a wonderfully good purple in winter, and having exfavoured rival in the plant called Shortia quisite flowers of pink. It, again, has a uniflora grandiflora, the handsome evergreen leaves of which also become purple, and the flowers, which are larger and more ornamental than those of S. uniflora itsself, being of a delightful shade of rose, passing off to pink. This is a charming plant for a cool house, or for one set apart for alpines, but it may also be cultivated in a frame. It is equally at home in the rock garden, where, in a moist spot, rather shaded, and in peat and sand, it will thrive well. It requires little after-attention when in the rock garden, but it must have occasional top-dressings of peat and sand. This shortia is one of the gems, which, although comparatively expensive, are worth many commoner and cheaper plants. Propagation is effected by careful division.

Saxifraga lilacina.

Some day the Royal Horticultural or the National Hardy Plant Society (unless by that time we have a National Saxifrage Society!) will have to take in hand the saxifrages and give us a list of "too much alike varieties." At the present time nurseries and gardens are being flooded with new saxifrages, some of them species, but many of them varieties, differing little from some of their neighbours. Yet there stand out some species which, for many years, are not likely to be bracketed with others as "too much alike," and one of these is the almost new, and very distinct, Saxifraga lilacina, one of the Kabschia set—a set best known to many by such species as S. Burseriana. S. lilacina is very distinct in its colour, which is pretty fairly described by the name. The tint may be called a good lavender-lilac. The plant makes a dense, low group of a pretty silvery colour, bearing on its stems of rather more than an inch high its handsome flowers, which are carried singly on the stems. It is a striking little saxifraga, hailing, I believe, from the Himalayas.

Unfortunately we are yet groping our way with regard to its cultivation, and, probably, a good many plants will be lost in the endeavour to discover its proper diet. Whether it will flourish more happily in the moraine or on a stony rockery is yet undecided, but it seems as if it would thrive in either, although it looks as if it preferred a certain amount of shade to full sun. A compost of loam, grit, some sharp sand, and a little leaf-soil, evidently answers well enough, provided that plenty of stones are among the soil. Some chips nicely tucked in about the plant will help to keep it cool. The cool moraine is recommended by some, and it must be said that this is an excellent situation for most of its class.

Patrinia palmata.

Not many of the patrinias are to be met with in the alpine gardens of to-day, and some of them are not, to say the least, of the most attractive character. They form a small genus, some of which come from Japan, and others from California. They belong to the same natural order as the valerians, and give umbels of small flowers in considerable numbers. P. palmata is among the best and most pleasing of the various species, and is one of the flowers which have been coming in increasing numbers from Japan to give us pleasure in our gardens. It has been seen on a few occasions during the past year, and has been much appreciated. It forms a dwarf plant only a few inches high, having neat, small palmate leaves, and from these rise little stems carrying large umbels of small yellow fragrant flowers.

Like others of the race, P. palmata does not give any special trouble if planted on a sunny rockery, which, although not parched with drought, is yet so freely drained that moisture does not stand about the roots. I am now trying it in a moraine, but it does not require this, and can be cultivated in loam, sand, and grit, with the addition of peat or leaf-soil. Its price is still high, but as it increases rather easily by division or seeds, it should soon be within the reach of the many.

Phyteuma comosum.

It must be many years ago since the writer was attracted to the curious Phyteuma comosum by an illustration in the catalogue of one of the leading firms of alpine plant nurserymen in the kingdom. There was something extremely fascinating in the well-grown plant, in between the rocks, and giving an abundance of its curiously-formed flowers. This was in the days when we had fewer photographic illustrations of alpines, and with added experience one has acquired doubts as to whether this picture was overdrawn or no. Yet the plant was so distinct and so quaint that it had to be purchased. Purchased it was, and flower it did, then when the rains of autumn came the enemy crept on it in the night and only the sorry remains of a once healthy plant remained. "Ichabod," was our lament, for the phyteuma was no more. The enemy was the slug, which a dry summer had prevented from emerging to devour its choice morsels until the rains came. The lesson is that whether the plant be easy to cultivate or not, it must be cherished, and kept safe from the slugs. They will scent it from afar, will flock to it, and regale themselves; and then we are left lamenting.

One wants to put this lesson and warning in the forefront, but still Phyteuma comosum is not difficult in other respects. Pack it among stones, limestone by preference, and if you haven't got that put some old mortar among the soil; give it a well-drained spot in good loam, with some grit in it, and you have every chance of securing its curious, quaintly-shaped flowers of deep, dull blue above its leathery leaves. But, above all things, beware of the slugs!

S. ARNOTT.

Erlangea tomentosa.—Where a greenhouse has to be kept gay at all seasons, this profuse flowering composite of comparatively recent introduction from Central Africa well merits attention. It is of a free branching habit of growth, and the flower heads, which are freely borne in loose corymbs, are of a deep lavender or lilac tint. The general aspect of the plant is that of a coloured eupatorium.—W.

Clerodendron speciosum. — Of the warm-house species of clerodendron that are naturally of a climbing habit, this is one of the most desirable, and for clothing the roof of a stove or intermediate house it can be well recommended. It is of garden origin, the parents being the deep scarlet or bright crimson-coloured Clerodendron splendens, a native of tropical Africa, and the well-known C. Thomsonæ. In C. speciosum the flowers, which are borne in loose corymbs, are very richly coloured, and it is less particular in its requirements than C. splendens.—S. W.

DAPHNES.

The daphnes are among the most delightful early-flowering shrubs of lowly growth. They are not difficult to cultivate; some are suitable for the rock garden, and others for the front of a choice collection of shrubs. Daphne mezereum and D. laureola succeed in ordinary garden soil, but the other kinds should have a compost containing sandy peat, or leaf-soil and sand incorporated. A well-drained position is essential, and when planting it is necessary to press the soil very firmly around the roots, as these shrubs resent a loose rooting medium.

Daphne Blagayana.

This is a charming evergreen that commences to flower early in spring, but this year its fragrant ivory-white blossoms were expanding in January. Everyone does not succeed with this species. It should be given a fairly open position in the rock garden, and planted in loam and sandy peat. It is an advantage to place stones among the branches when they are large enough, as if for layering. This helps to maintain a uniform moisture at the roots during the summer months, and the plants certainly thrive under these conditions.

Daphne cneorum.

In this plant, which is known as the garland flower, we have one of the most beautiful of all the daphnes. Its attractive, rich, rose-pink blossoms are produced during April and May, and sometimes also in the autumn. The dark evergreen foliage forms a good setting for the clusters of bloom at the ends of the growth. The flowers are deliciously scented, and continue in a fresh condition for several weeks. It succeeds under similar conditions to those suggested for D. Blagayana, and is benefited by an occasional top-dressing of compost similar to that in which it is growing.

Daphne mezereum.

This is a popular winter-flowering shrub, and one that succeeds under ordinary conditions in a mixed shrubbery. It commences to produce its fragrant blossoms on the leafless branches at the end of January, and usually continues to flower until April. The purplish-red blossoms literally cover the branches. Under favourable conditions the shrub will attain a height of five feet. There is also a white-flowered form which is worth growing.

Daphne alpina and D. Genkwa.

The first is a deciduous species, with beautiful white flowers, produced during the spring. It is not a vigorous grower but is of branching habit, and sometimes attains a height of two feet. D. Genkwa bears fragrant lilac-coloured blossoms in the spring before the leaves unfold. This species is not quite hardy in cold districts, and should be planted against a wall except in favoured localities. D. striata is a trailing kind, suitable for the rock garden. It bears sweetly-scented rosy-purple blossoms in June and July.

Daphne indica and D. laureola.

Perhaps this is the most tender of all the daphnes, and it is certainly one of the most fragrant. It can be grown out of doors, on walls, near the west coast of Ireland and Scotland, and in similar warm localities. In cold districts it is worth the protection of a greenhouse.

D. laureola is an evergreen species that produces its yellowish-green flowers early in the year, and, in common with some of the other kinds, succeeds well in partial shade. D. pontica is another evergreen, bearing yellowish flowers in April and May, and is quite hardy. J. GARDNER.

THE MARK OF SUPREMACY

"Give thy CLAY
To FERTILIZE the Soil."—
Byron.

INCLUDE THIS
STANDARD PLANT FOOD
IN YOUR SEED ORDER.

Used in the Royal Gardens, throughout the grounds of the Royal International H rticultural Exhibition, 1912, by Local and Municipal Authorities, and by Horticulturists universally.

We offer all the choicest stocks of **Vegetable and Flower Seeds** at the **Lowest Profitable Prices.** We feel confident that many amateurs now paying from 25 to 50 per cent. more than we charge would, if they gave us a trial, find the results equally good, and they would have the surplus to spend in other directions. We quote below a few specialities.

Many of our friends and customers having told us that *ounces* of seed were often far more than they required, we have lately, for the convenience of those with small gardens, put up packets at **2d.** and **3d** for their convenience. We also offer nearly all the Hardy Annual Flowers in (liberal) **2d.** packets.

Fully Illustrated Catalogue Free on Application.

PEAS.

Gradus 1/-, Thos. Laxton 1/2, Reading Wonder 1/-, Triumph 8d., Prince of Wales 8d., Autocrat 9d., Prizewinner 1/-, Capt. Cuttle 1/-, Little Marvel 1/-, The Gladstone 1/-. ALL PER PINT.

All the best **BEETS** from **6d.** to **1/-** per oz.

„ **CABBAGES 6d.** to **8d.** per oz., **2d.** per pkt.

„ **LETTUCES** from **6d.** to **1/-** per oz., **2d.** and **3d.** per pkt.

Nearly all the best **ONIONS 6d.** to **1/8** per oz.

RADISHES 2d. to **3d.** per oz.

The BEST TOMATOES.

Best of All (Sutton), the best exhibition variety, **6d.** and **1/-** per packet.

Sunrise (Carter's), the heaviest cropper in cultivation: fruit perfect in shape and excellent in flavour, **3d.** and **6d.** per packet.

Smith's Ruby Cluster, an extremely free cropper; colour, shape and flavour excellent, **3d.** and **6d.** per packet.

Up-to-Date, very short jointed in habit, and extremely prolific. Fruit smooth, medium size, excellent quality, **3d.** and **6d.** per packet.

Kondine Red (Holmes), a wonderful cropper, **6d.** and **1/-** per packet.

ALL THE ABOVE ARE SAVED FROM SELECTED FRUITS.

CHOICE PRIMULAS.

We have a magnificent strain of these. The seed is saved in our own houses, with the utmost care. All seed is 1912 crop, and *certain* to grow if it has a fair chance. Large flowered varieties—**Brilliant King**, intense crimson; **Cannell's Pink**, gigantic flower, peach blossom colour; **Brilliant King**, deep velvety crimson; **Mrs. Robt. Cannell**, lovely white with deep red stems; **Pink Perfection**, pure light pink; **The Duchess**, white, with centre of rosy carmine and yellow eye; lovely **White Perfection**, fern leaved, the largest white. All these in separate packets, at **1/-** per packet. Also mixed, from above varieties, **1/-** per packet. **Stellata Mont Blanc**, and finest mixed, **1/-** per packet. The packets contain about 120 seeds.

A Fine Selection of Seed Potatoes—Scotch Grown.

J. R. PEARSON & SONS, "THE NURSERIES,"

LOWDHAM, NOTTS.

Established 1782.

CLEMATIS HERACLEÆFOLIA VAR. DAVIDIANA.

This showy clematis belongs to a small group of late summer and autumn-flowering kinds, which are characterised by a sub-shrubby habit, large, rather coarse, and usually three-parted leaves and small tubular flowers of a bluish colour. Some botanists accept but one species, and include the four or five named kinds as varieties of C. heracleæfolia, whilst others give three sorts specific rank. By the intercrossing of the various kinds a number of hybrids have been raised, some of which are superior to the parents in colour of flowers and floriferousness.

C. heracleæfolia and all its forms are similar, so far as habit is concerned, and all require similar treatment. Growing from 2 to 3ft. in height, the upper half of each young shoot is transformed into a large inflorescence, the small, tubular, bluish flowers being in clusters from short axillary growths and also in panicles from the ends of the branches. After flowering the whole of the portion which has produced flowers dies, therefore it is necessary to prune all the shoots to within a few buds of the base each spring. If desired, the plants can be staked, and the branches kept in an upright position, but a group is more pleasing when the branches are allowed to arrange themselves naturally, as in the accompanying illustration.

Providing good loamy soil is given, no difficulty need be experienced in the cultivation of any member of the group, while propagation may be effected by division of the clumps in spring or by grafting dormant eyes upon strong roots of C. Vitalba.

C. heracleæfolia var. Davidiana is, like the type, a native of China, and one of the most ornamental of the older kinds, the growth being more vigorous and the flowers deeper coloured than is the case with either C. heracleæfolia, or its varieties Hookeri and Stans. The variety Lavellei is, however, more floriferous, and brighter-coloured than Davidiana, and should always be selected when one form only is required.

The various hybrids raised by the late M. Lemoine, of Nancy, are all showy, and include such kinds as Azur, with large panicles of clear blue flowers; Columbine, with very large, violet-coloured blooms; Hybrida, having compact trusses of large pale blue flowers; and Iris, with deep blue flowers, borne in great profusion.

Although none of the kinds grow much more than three feet in height in the open ground, they may be grown considerably taller against a fence or wall, providing care be taken in the pruning to prune no lower than the highest well-developed bud, and to ensure good, deep loamy soil in the first instance, with an occasional surface dressing of well-rotted manure afterwards, for all are rank feeders, and quickly deteriorate if the soil becomes impoverished.

Kew. W. DALLIMORE.

SALPIGLOSSIS.

A bed of these plants, when in full flower, forms one of the most beautiful features in a garden from the early part of July to the middle of September. Experienced cultivators know well how to raise strong examples that will prove satisfactory, but the inexperienced may fail to grow good plants. Although they are not difficult to manage, much care is necessary if the best results are to be secured.

Many batches of plants are spoiled when they are in the seedling stage. If allowed to remain in an over-crowded state too long, or not transplanted while very small, even when they have ample space to grow in, the plants soon begin to flower and the stems harden. Afterwards, it is a difficult matter to get them to grow freely, branch out, and bear large finely-coloured flowers.

The seeds should be sown thinly in pots or pans not later than the middle of March. If placed in a warm structure the seedlings will soon appear, and, in due course, they must be pricked out in boxes 4in. deep. The next move must be to a bed in a cool frame. A fair quantity of sweet leaf-soil and well-rotted manure should be passed through an inch-mesh sieve, and added to the loam in the frame. Use coarse sand with the compost, but also put some on the surface of the bed.

Slugs are very fond of these plants, and must be guarded against, as they will soon destroy tiny specimens. It is important that they be grown sturdily and transplanted with good balls of soil adhering to the roots.

A somewhat sheltered border, with a background of shrubs, but open to the sun and very light, is an ideal position for salpiglossis to blossom in.

GEO. GARNER.

CLEMATIS HERACLEÆFOLIA DAVIDIANA.

A sub-shrubby plant, with an abundance of small, tubular, blue flowers.

Giant Groundsels.—Among what may be regarded as giant members of the great Groundsel family must be included the two Mexican species—Senecio grandifolius and Senecio Petasites, both of which bloom during winter and early spring. Almost a tree in stature, although it will flower freely when but a few feet in height, S. grandifolius has large, coarsely-toothed leaves, and massive, densely-packed heads of yellow flowers. Senecio Petasites is less sturdy in growth, and the flowers are disposed in a loose, terminal panicle. The leaves, too, are lobed, hence it has been given the specific name of S. platanifolius, while S. grandifolius is also known as S. Ghiesbreghti.—W.

GRAPE MRS. PEARSON.

An amber-coloured grape of good appearance and of great excellence is the variety named Mrs. Pearson. It derives its origin from the same parents as Golden Queen, that is to say, it was obtained by crossing Alicante with the small-berried and deliciously-flavoured variety Ferdinand de Lesseps. The latter is the result of crossing Royal Muscadine with the Strawberry Grape, and was raised, like Mrs. Pearson, by Mr. John Pearson, of Chilwell, Notts. Both Mrs. Pearson and Ferdinand de Lesseps have secured a First Class Certificate from the Royal Horticultural Society, the former in 1874, and the latter in 1870.

The variety Mrs. Pearson is not very largely grown, but where it is cultivated it being of robust constitution and vigorous growth. The bunches are large and well-shouldered, and the berries, of roundish, oval form, are about an inch long. When the variety is very well finished there is a pink tinge on the amber skin. Mr. T. Pateman, gardener to C. Cain, Esq., The Node, Welwyn, grows this grape well; and the bunches illustrated represent those he exhibited at the great fruit show held in the Royal Horticultural Hall, Westminster, in October last, and with which he won the first prize in the any "other white" class. Curiously enough, the two other competitors in the class also showed Mrs. Pearson grape, and both of them exhibited clusters of good size and remarkable for rich finish. of good size and remarkable for rich finish.

NOTES FROM SCOTLAND.

The present winter, so far, has not been of a type, in regard to weather, that gardeners may view complacently. Throughout the south-west of Scotland the unusually severe frost in the closing days of November, though of short duration, wrought much harm, and, in some cases, destruction to green crops, broccoli especially suffering very severely, while even such hardy subjects as cabbages, savoys, and Brussels sprouts did not pass unscathed. This was probably due to the immature condition of the vegetable tissues after the almost sunless summer and heavy rainfall last year. Following closely upon this, the excessive rainfall of December precluded scarcely any advance being made with ground work, hence this in general is greatly in arrears, and many garden plots are foul with weeds and grasses that it was almost impossible to keep under control at the customary time and manner.

The New Year commenced more favourably, but on January 11 the greatest snowstorm experienced for nearly twenty years occurred, and, being accompanied by a piercing wind and frost, drifting to an unusual extent took place. The remnant of this storm still (January 28) remains, and wreaths of snow formed in hollows, several feet in thickness have, owing to alternate changes of rain and frost, been rendered so hard upon the surface that one may pass over them with ease and safety.

This of itself would not be a serious matter at this season, but, on the other hand, the damage done to trees and shrubs on many estates, owing to the amount of snow finding a lodgment upon the branches and becoming frozen thereto, thus producing a weight greater than they could bear, is truly appalling. Large and sturdy trees of the cedar tribe, that have successfully withstood the storms of many years are now much broken, and will be sadly disfigured for a long time to come. Many others with more yielding branches had these weighted down to the stems, or the lowermost to the ground line, and although relieved of their unwonted burden they still remain in much the same position, but will doubtless regain their former attitude in due course.

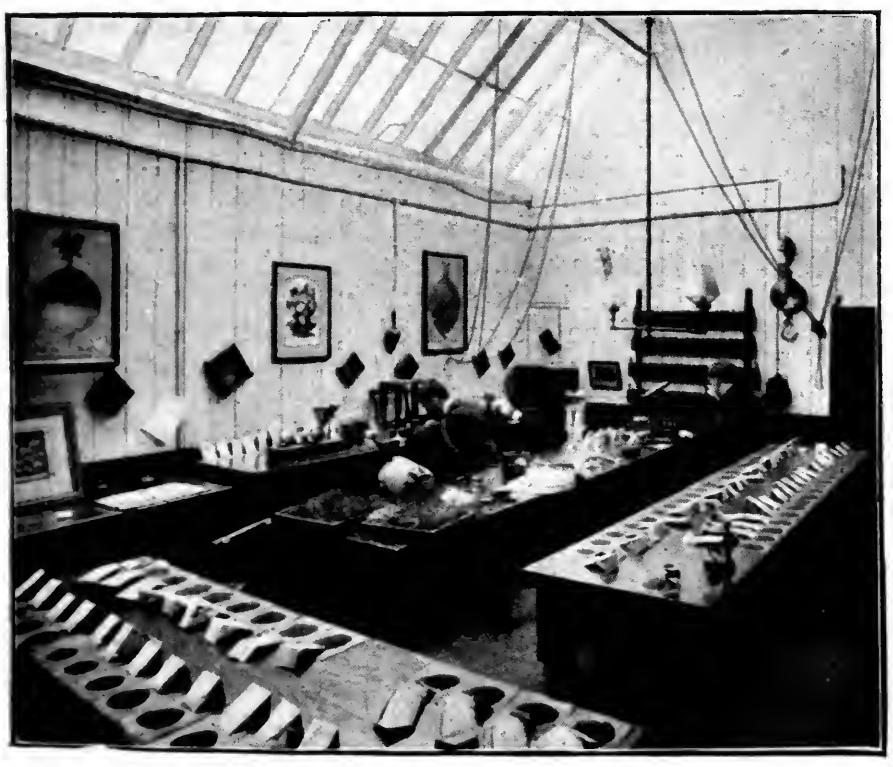
Shrubs of most kinds had at first a most dejected appearance, being opened out on every side, but while some of the more rigid branches are broken, others will probably gradually assume their former positions, so that, in the end, less damage may have accrued to these than was at first anticipated. With a continuance of the present wintry conditions a scarcity of green vegetables in the near future may be expected, as growth for a long time past has been at a standstill. JAMES DAY.

MR. T. PATEMAN'S PRIZE BUNCHES OF MRS. PEARSON GRAPE.
Exhibited at the Royal Horticultural Hall in October, 1912.

Ruellia amœna.—This acanthaceous plant is remarkably free flowering, and, what is more, very brightly coloured. Neat little bushy plants grown in five-inch pots are very useful for various decorative purposes. The flowers are shorter than those of most of the ruellias, and have a particularly inflated tube.—T.

THE SEED INDUSTRY OF THE UNITED KINGDOM.

To the average man who makes his garden a hobby, and who annually spends a few pounds or shillings on seeds, there probably appears to be little of interest to write about under the title of "The Seed Industry of the United Kingdom." The practical gardener knows well enough that conducting a business as a seedsman involves more than putting seeds into packets



A CORNER OF A SEEDMAN'S LABORATORY.

and finding a sale for them by publishing catalogues and advertisements. But it is doubtful whether we fully realise, when we unpack our parcels of seeds, the immense amount of care, skill, and labour that has been expended upon those seeds, or that we give a thought to the vastness and importance of the seed industry in all its ramifications, not only in the warehouses of the leading firms, but on the markets and exchanges, and also on the farms and trial grounds where the seeds are grown and proved.

Even from the point of view of economics the amount of capital invested, and employment entailed, places the seed industry among the important businesses of the country.

Imports.

Much of our seed is, of course, imported, and, according to the returns of the Board of Agriculture, there were imported during the year 1911 2,581,567 lbs. of garden seeds, the value of which amounted to £112,637. In addition to this there were 1,676,049 cwts. of seeds unenumerated, valued at £558,682. Bird seeds are included in the latter class, but there must also be a considerable proportion of flower and other seeds in small consignments which are not deemed of sufficient importance for separate classification. Clover and grass seeds are entered separately, the returns for 1911 being 11,681 tons, costing £550,071. This was the smallest importation of clover and grass seeds for a period of at least eleven years. In 1910 the quantity was 14,349 tons, worth £664,170, while in 1903 the figures were 22,902 tons, representing £1,008,772.

In addition to all this it may be mentioned that a considerable portion of the grain imported is, of course, used for seed, although it is not statistically separated from grain for food. The same may be said of peas and beans, and, to a certain extent of potatoes. Probably in future years, now that a new horticultural department of the Board of Agriculture is in course of formation, more detailed returns will be available, but even the foregoing conveys some idea of the vast quantities of garden and farm seeds that are imported into this country. It may be thought that the sums quoted as being the value of these seeds are extremely low, but it must be remembered that they indicate only first cost in bulk, and, as will be shown later, there is, in addition to carriage, a large amount of labour and expense involved before these seeds can be handed over to the customer. Turning to another Board of Agriculture publication, which deals with the extent of

Home Cultivation,

we learn that "a considerable area is devoted to the growth of crops for seed." Clover, vetches, trefoil, mangolds, turnips, and swedes are mentioned as being cultivated for the purpose on the largest scale. In 1908 nearly 13,700 acres produced 5,400 tons of seeds of these crops alone, the value being £132,000. The report mentions beans, beetroot, broccoli, cabbage, kale, kohl rabi, onions, parsley, parsnips, radish, rape, rye, rye glass, sainfoin, and timothy, all as recorded seed crops, but no figures are given as to the quantity of land they occupy, or of seed harvested. We know well enough, however, that quite a number of firms exist who conduct on very extensive lines the business of seed growers, and in many instances their seed farms occupy from 300 to 500 acres. Again we know many a private estate where the head gardener grows special types and varieties of both flowers and vegetables for seed on contract for the trade, and in this connection it is interesting to note that one of the most successful growers of high-class wheats for seed is a prominent gardener whose name and writings are well known to readers of the GARDENERS' MAGAZINE.

It remains only to remind readers of the extent and importance of the seed potato trade, of the wonderful increase during the past few years in the quantity of home-grown sweet pea seeds produced and sold by specialists, and of the large area of glass-house accommodation that is devoted to the production of seed of cucumbers and tomatoes, as well as of begonias, primulas, cinerarias, and hosts of other flowers, to show that if complete returns were available the seed harvest of this country would represent no mean sum, while its production must provide either the sole or partial means of livelihood for a large number of both male and female workers.

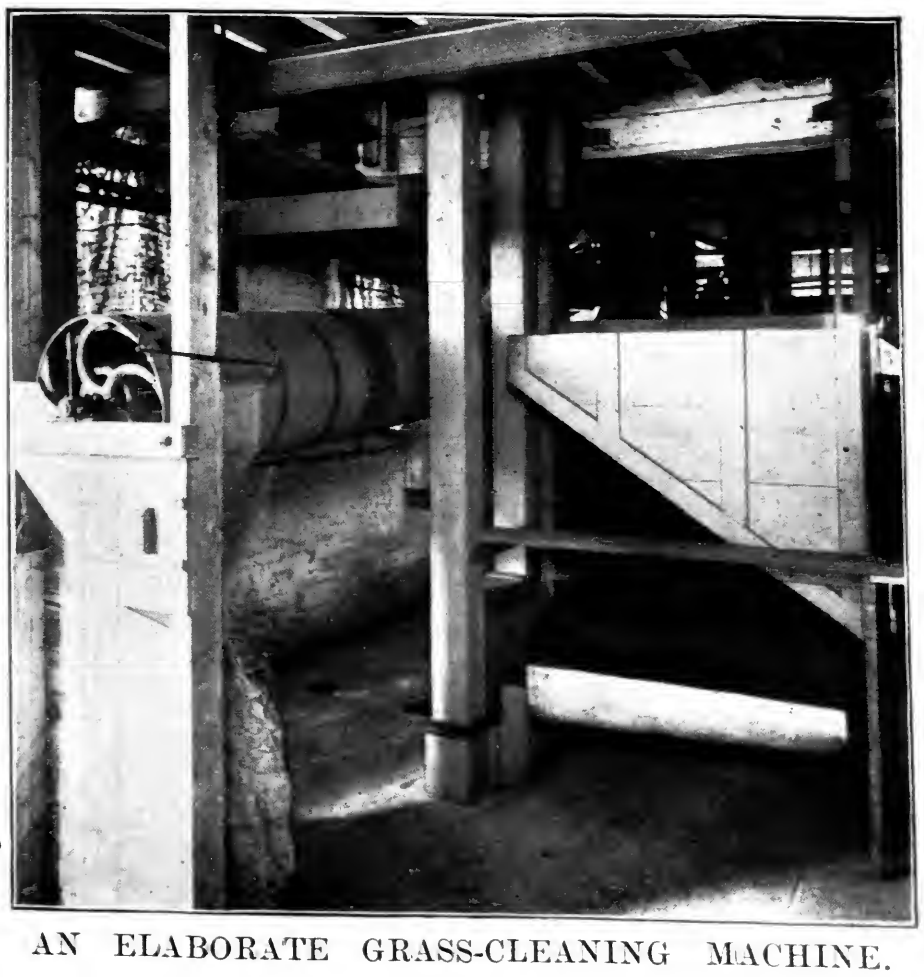
The Warehouse and Laboratory.

Apart, however, from consideration of bulk and extent of production, there is no lack of interest to be found in the contemplation of the seedsman's calling. The interior of a modern seed warehouse consists of much more than drawers and bins, weights, and measures. It has its laboratory, furnished with scientific instruments of varied uses, its testing chamber, and its cleaning room, wherein will be found cleverly designed and constructed machines that accomplish many tasks impossible of achievement by hand and eye. By courtesy of Messrs. Sutton and Sons, Reading, an illustration is given of a corner of their laboratory, where, as is shown, experts are engaged among innumerable samples of seeds that are subjected to careful examination through powerful microscopes, and submitted to experiments with the object of discovering the slightest blemish.

Seed Cleaning.

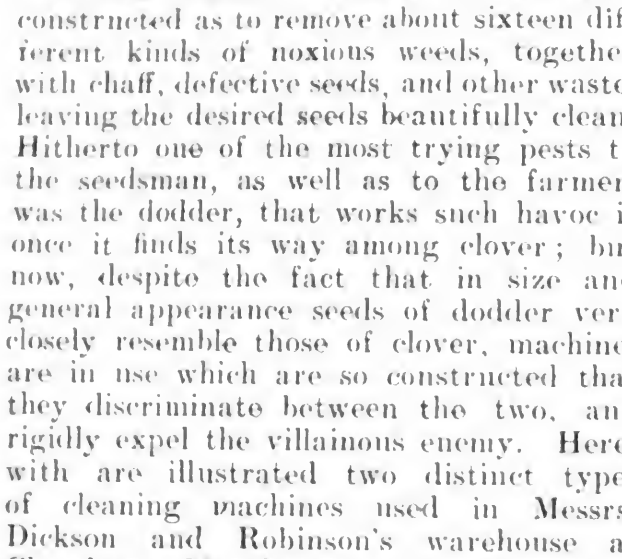
We are accustomed, when we order an ounce of seed, to receive an ounce of seed, unmixed with chaff, dirt, or stalks, but many devices are brought into use to get rid of impurities previous to packeting. It is impossible, when harvesting seeds in bulk, such as corn, clover, peas, and many other crops, to avoid gathering also a considerable quantity of undesirable seeds of weeds, and these must all be extracted before the seed is saleable.

The poet may express in flowing rhyme his admiration of the poppies among the corn; the artist may paint the golden charlock and the downy thistle, but the seedsman must sink capital in wonderful machinery for the purpose of ousting from



AN ELABORATE GRASS-CLEANING MACHINE.

his stock the seeds which would otherwise bedeck many another field, but spoil the farmers' crops. Quite recently was seen at work one of the most up-to-date of these machines in action. This machine was so constructed as to remove about sixteen different kinds of noxious weeds, together with chaff, defective seeds, and other waste, leaving the desired seeds beautifully clean. Hitherto one of the most trying pests to the seedsman, as well as to the farmer, was the dodder, that works such havoc if once it finds its way among clover; but now, despite the fact that in size and general appearance seeds of dodder very closely resemble those of clover, machines are in use which are so constructed that they discriminate between the two, and rigidly expel the villainous enemy. Herewith are illustrated two distinct types of cleaning machines used in Messrs. Dickson and Robinson's warehouse at Cheetham, Manchester. The grass machine is one of the largest and most useful machines yet invented. Its intricate mechanism cannot be shown in a photograph, but suffice it to say that the seed as harvested is fed from a huge hopper on a floor above into the machine, and passes over fine screens, and through the revolving cylinders, ultimately being passed down a shute into bags on the floor beneath absolutely freed from seeds of dock, rib grass, field madder and other extraneous rubbish that may have been present. The other illustration shows a quite different type of machine, which is used for what may be termed hard seeds, such as clover, turnip, rape, etc., whilst mangold,



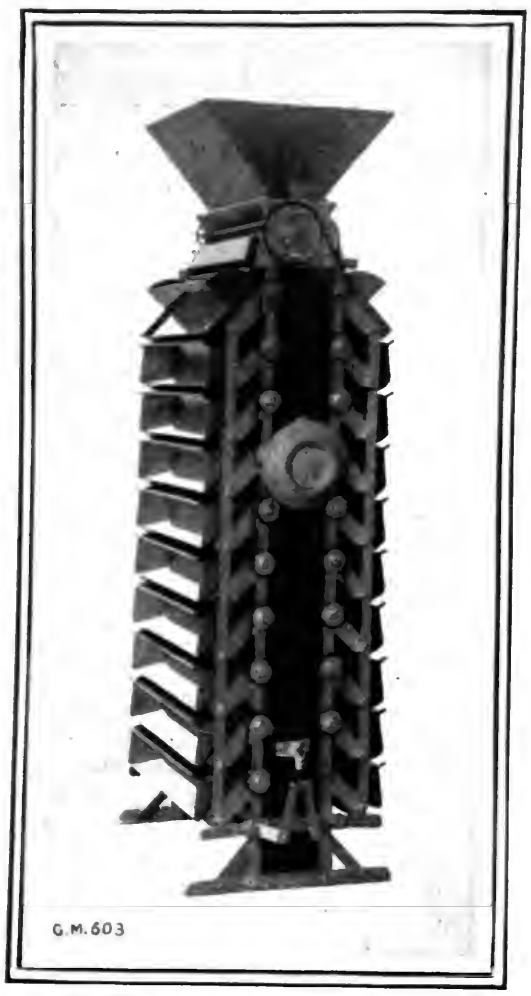
GERMINATED ONION SEEDS.

pea, cabbage, and other seeds necessitate the use of equally clever machinery of various patterns.

It is worthy of note that many seeds of weeds are strictly forbidden admission into our colonies and foreign countries. The Government of Canada have a list of twenty-four weeds which may easily accompany carelessly handled farm seeds, and the importation into the Dominion of farm seeds containing seeds of these weeds is prohibited on pain of heavy penalties. Notwithstanding this fact, our leading growers are able to export to Canada, as well as other countries, considerable quantities of the finest pedigree wheats, barleys, and other grains, the purity of their stocks being unsurpassed.

Testing Seeds.

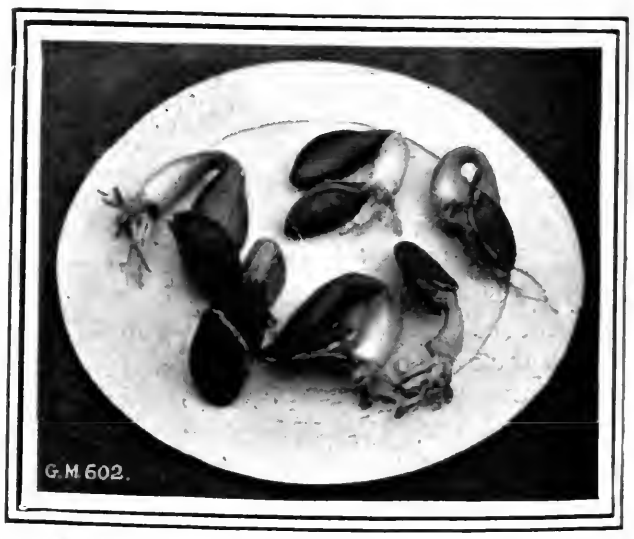
It is, of course, the custom with all the leading firms to test the germinating power of every batch of seed handled. The buyers attached to the large wholesale houses resort to various methods of estimating the worth of the various samples offered them; an experienced man can tell much by aid of eye and hand alone, but in a good many instances it is necessary to seek assistance from microscope, electric light, etc. At



A MODERN SEED CLEANER.

least one of the large firms in this country has installed in a special room a remarkable electric apparatus, which gives nothing short of an artificial daylight. Immediately under the ceiling are a series of large glass tubes. By some mysterious combination of electric current and chemical vapours these tubes can be flooded with a perfect light, so that on the dullest day, or the darkest night, the firm's expert may have all the advantage of clear daylight for the purpose of examining the many samples of clover and other seeds that of necessity pass through his hands. Some day, doubtless, some such system of lighting will become general in our shops and dwellings, if not, indeed, in our streets, but to the enterprise of our seed trade will belong the honour of leading the way in regard to the use of a perfect artificial light, so pure that the slightest variations in colour may be detected. It matters not, however, how certain the most expert buyer may be that his seed is right, there is still a thorough test to be made of its germinating power. Time was, we are sometimes reminded, when seedsmen were not particularly careful as to the age, or soundness, of the seed they sold. We have heard and read how unscrupulous firms, once upon a time, made huge profits by actually buying dead seed at trifling cost to mix with new, with the result, of course, that one might sow thickly, but obtain a very thin crop. To-day, however, and be it known the change is due to the painstaking efforts of seedsmen of repute, we may, if we will but do business with firms having a good reputation, buy our seeds with the confident expectation of obtaining very close upon a hundred per cent. germination.

It is not so many years ago since testing meant simply sowing a pinch of seed in a shallow tray of soil, and watching results when placed in a warm house. Moist flannel soon took the place of the trays of soil, germination thus being hastened, but step by step the methods of testing have been improved, until to-day what may virtually be called seed incubators are in general use in all up-to-date establishments. An illustration given herewith shows one of the most modern seed germinators filled with the samples of seeds on small discs of blotting paper. To Messrs. James Carter and Co., Raynes Park, belong the credit of the improvements in this over older patterns, many of these excellent germinators being in constant use in their large testing room, from whence the illustration was obtained. A definite number of seeds are evenly distributed over the surface of each disc, so that by counting after germination the exact percentage can be ascertained. The tank of water in the base of the incubator is kept at an even temperature by the use of a gas jet or lamp, and by closing the glazed front sufficient moisture to promote rapid



GERMINATED VEGETABLE MARROW SEEDS.

germination is retained. Other illustrations from the same firm show two discs on which are seeds after a day or two's growth, and it will be seen that very few seeds have failed.

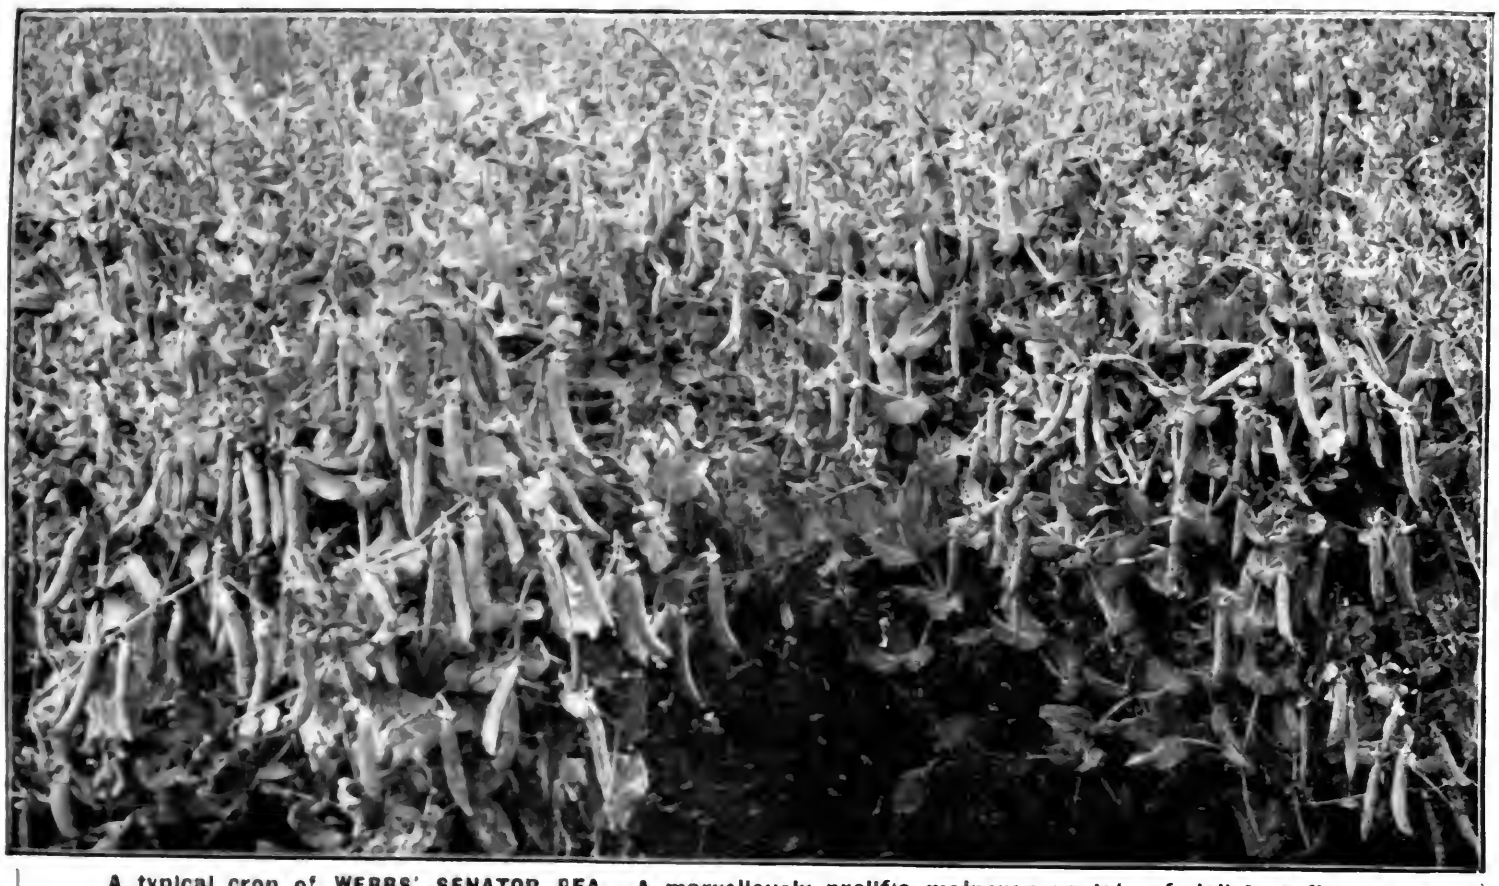
WEBBS' PERFECT PEAS.



A typical crop of WEBBS' SENATOR PEA. A marvellously prolific maincrop variety of delicious flavour.
Awarded R.H.S. First-Class Certificate. **1/9** per pint; **3/-** per quart, post free.
BEST CULINARY PEAS IN 1912.—"Senator gave by far the heaviest crop I have ever seen it carry and that is saying a good deal, for this grand Pea is one of the most prolific varieties I know. It ought to be found in every garden where a big return of high-class Peas is required." C. BLAIR, Preston House Gardens, Linlithgow. (*The Gardener*, Dec. 28, 1912.)

Seedsmen to *H.M. The King*

WEBBS' EARLY FAVOURITE.
First Early.
2/- per pint, **3/6** per quart.
MR. A. TUMMEY, Head Gardener to SIR THOMAS BARCLAY, writes:—"Early Favourite is a very heavy cropper of excellent flavour. The best early dwarf pea I have ever grown."

WEBBS' STOURBRIDGE MARROW
Second Early.
2/- per pint, **3/6** per quart.
MR. H. KEEP, of Aldermaston, writes:—"I won First Prize at Reading Show for the third time in succession with Stourbridge Marrow Pea. It was the best row of peas I have ever seen."

WEBBS' NEW "KING GEORGE."
Main Crop.
1/- per packet, **2/6** per pint.
MR. A. R. SEARLE, Head Gardener to THE MARQUIS OF NORTHAMPTON, writes:—"I grew 'King George' Pea for exhibition and it was the finest we had. The pods measured 7¼ inches in length and were well filled."

WEBBS' SELECTED GLADSTONE.
Late Crop.
2/- per pint, **3/6** per quart.
Winner of First Prize at Shrewsbury Floral Fete, 1912, open to the Kingdom.

Illustrated Catalogue for 1913, Gratis and Post Free.

SURETY SEEDS.

The very finest strains of Vegetable and Flower Seeds.

The life, vitality, and germinating power of "Surety" Seeds are thoroughly tested before we send to you. Buy "Surety" Seeds, and there is no uncertainty about the growth. It's **bound** to come.

To-day is better than any other time to write for a free Catalogue:

JAMES BACKHOUSE & SON, Ltd.,
The Nurseries, YORK.

TO ENSURE SUCCESS

Only seeds of good pedigree and selection should be entertained. The following are stocks that have been repeatedly selected, tested, and approved, and can be recommended with every confidence.

Harrison's Lord Leicester Pea produces an abundance of exhibition pods, well filled with peas of rich flavour. Height, 4ft. ... ... Per quart, **2 8**
"Your Lord Leicester were a great success."—T. C. HEDGES, Esq.
"I have grown peas for 20 years, but this is the masterpiece."
—J. SHEPPARD, Esq., Bristol.

Harrisons' Little Wonder Cabbage, for spring sowing. The most perfect and quickest cabbage. See illustration in our Catalogue—free. Per packet, **1/-**
"Your Little Wonder is the quickest growing that I have tried. Planted at the same time as another well-known variety; it was fit to cut at least a fortnight earlier."—Mr. W. GIBSON, Head Gardener to R. W. KAYE, Esq.

Harrisons' Improved Eclipse Cauliflower. For illustration see Catalogue. Per packet, **1/-**
"An excellent type of a first-class cauliflower, producing heads of solid whiteness, capital for the dining table."
—Mr. D. ROBERTS, Head Gardener to HUSSEY PACKE, Esq.

Harrisons' Royal Malta Lettuce. A.M., R.H.S. Quite distinct. Per ounce, **1/6.**
"It is the best I have ever grown. It is quite distinct, large, and crisp. I intend to grow it as my principal crop."
—Mr. THOS. OLDHAM, The Gardens, Stoughton.

Harrisons' Leicester Globe Onion, Beds Champion type. Per ounce, **1/-**

Harrisons' Leicester Keeping Onion, pale straw colour, Per ounce, **1/-**

Harrisons' Banbury Cross Onion, a famous strain. Per ounce, **1/-**

Harrisons' Ailsa Craig Onion, unrivalled stock. Per ounce, **1/6.**

Harrisons' Icicle Radish, delicate flavour, crisp and refreshing; greatly appreciated by all. Per ounce, **4d.**

The above and many others of excellent value are in Harrisons' New Catalogue, which fits the pocket. It is free, and contains cultural directions and many hints of value to the lover of gardening. Orders value 10s. and over, carriage free.

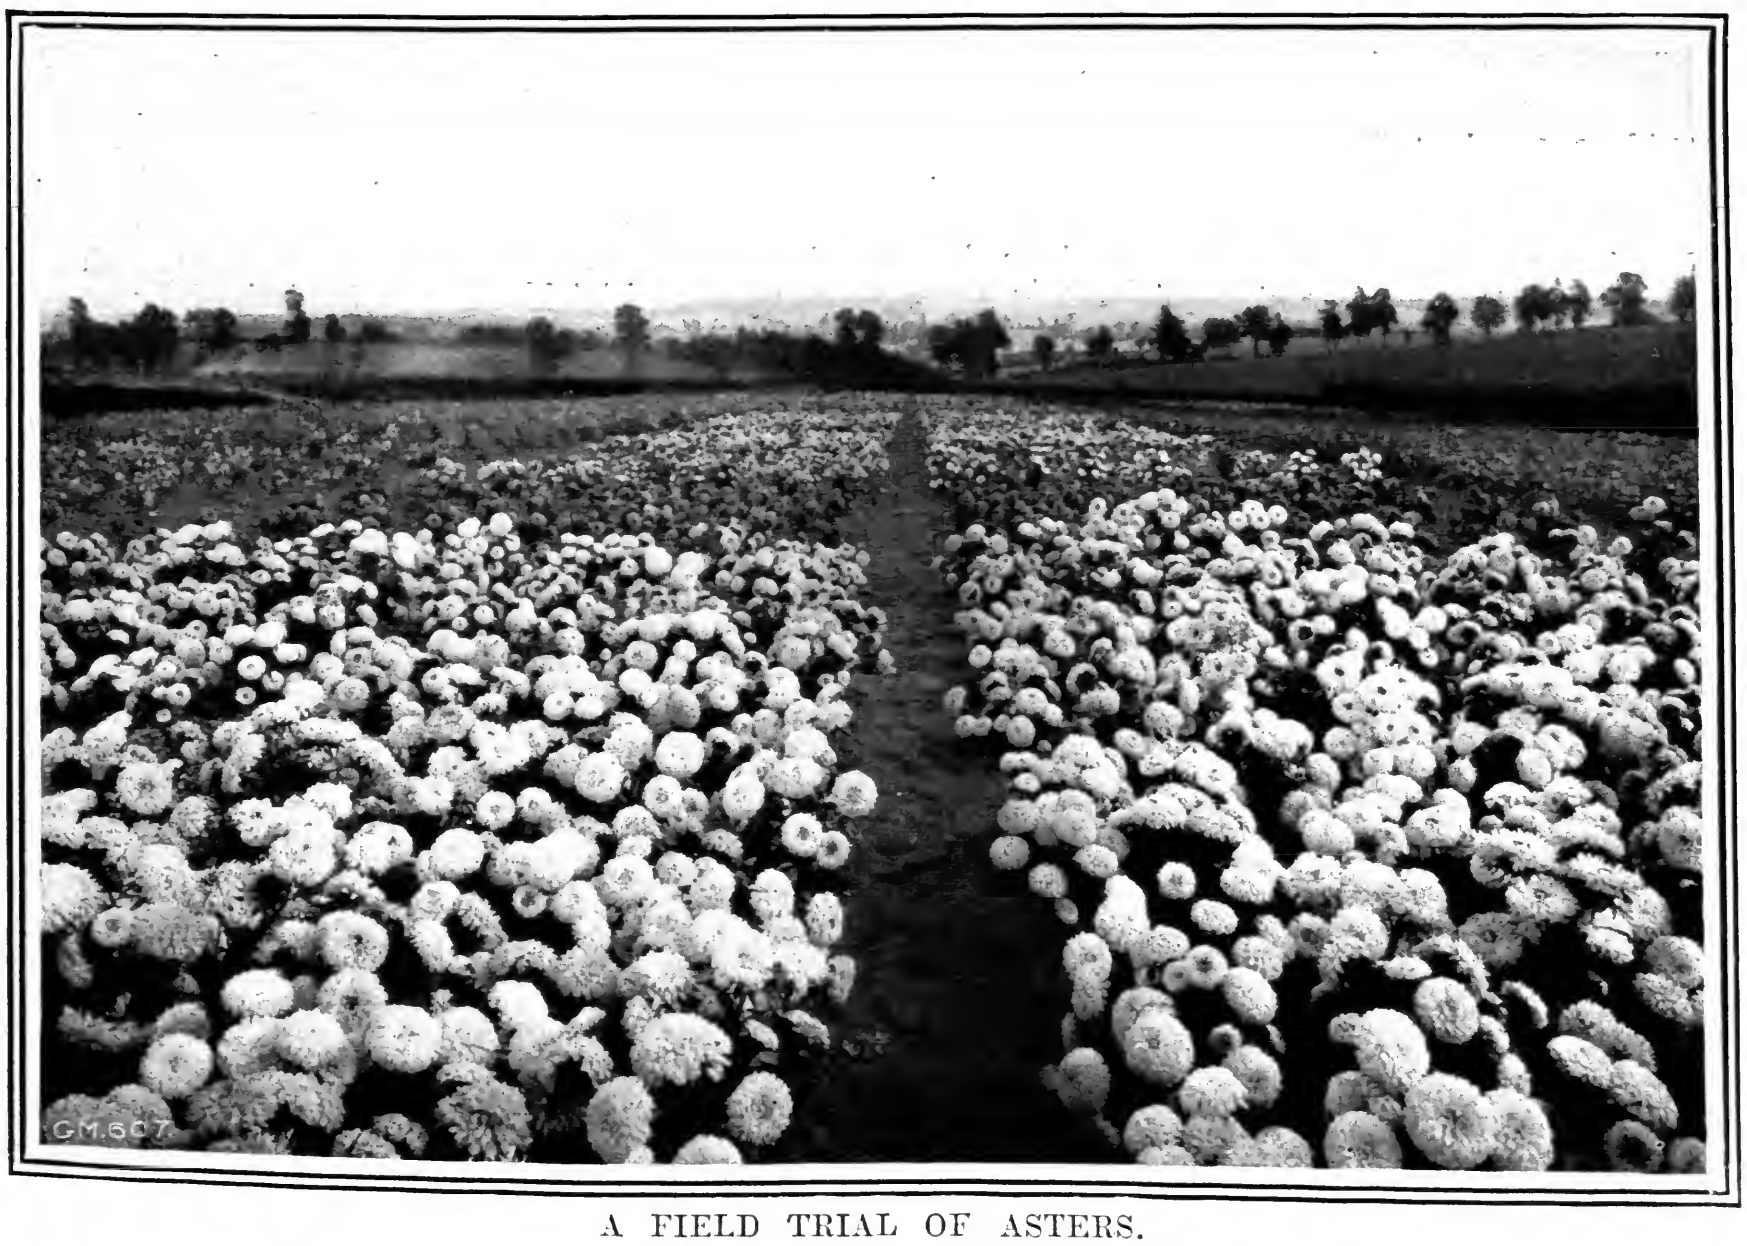
HARRISON & SONS (ESTD. 1764), Royal Midland Seed Warehouse, LEICESTER.

Harking back to seed grain, it is a matter of immense importance that any vestige of fungoid disease or injurious germs shall be detected, and this involves extreme care. It is not sufficient even to examine through a powerful microscope, for, in some cases, the mycelium or the germ is the same colour as the outer skin of the grain. The most interesting method adopted is to place a few grains, with a little distilled water, in a funnel-shapel glass tube. The tubes are fixed to a little apparatus, which, by electric current, is driven by centrifugal force at such a speed that the water is practically dried up, but any germs or spores are left adhering to the glass, and are then detected by the aid of magnifying glasses. Needless to say, samples upon which deleterious germs are found are discarded as unsatisfactory for seed. Other apparatus exist for ascertaining the quality of roots, such as sugar beet, mangolds, or swedes. One machine cuts out a cube from the centre of the root. This cube is placed in a combined still and oven, which first evaporates and then distils all the water from the pulp. It is then possible by analysis to determine the proportion of sugar in a beet, and the feeding value of a mangold or a swede, the object, of course, being to ensure selection of the most valuable to be retained for producing next year's crop of seed.

POLLINATING PRIMULAS.

The Trial Grounds.

The greater part of the work of selection and proving of quality must, of necessity, be done in a more natural way by growing under natural conditions, and the reader may now with advantage be taken to the trial grounds, which are another important feature of a seed grower's or merchant's



A FIELD TRIAL OF ASTERS.

establishment. It is not sufficient to know that one's seeds are clean, nor even that they will grow. It must be determined that the stock is true to name, and fully up to standard of type, strain, or variety. Hence the importance of the trials conducted by experts qualified to decide what is, and what is not, true and genuine. Every gardener is well aware that among plants like does not always produce like. Reversion to type, fertilisation by insects, and other forces are constantly at work to undo what, from Nature's point of view, is the artificial or spurious development in our improved types and strains. We breed an onion, a pea, or a cabbage which, from the cook's or the exhibitor's standpoint, is far in advance of older favourites, but left to itself and simply seeded and sown year after year, it will not long retain its distinctive merits. Even an unfavourable season will work havoc among our choicest flowers and vegetables if extreme care is not exercised, because trying weather punishes the highly-developed specimens more than the rest even of the same batch, because the smaller ones more nearly resemble the original types. The consequence is there is a danger of saving seed from just those specimens that will readily throw back, or revert to the inferior type from which the variety was bred. Hence it is that every seed grower must constantly prove his stocks, weed out every individual that shows the slightest sign of deterioration, and retain for seed only the very best. Some faint idea of the labour entailed by these trials will be gained by a glance at the accompanying illustration, which depicts the trial of asters at Messrs. E. Webb and Sons' trial grounds at Kinver. When it is borne in mind that every subject of which seed is offered is subjected to trial in similar manner to that here shown, and that in the case of the large firms the trial grounds alone cover many acres of ground, one may realise that genuine seed is worth its price.

Passing reference has already been made to

Seed Production under Glass,

and in this department material might be found for a lengthy article. In the case of many subjects, such as primulas, begonias, and others of our favourite greenhouse flowers, each flower is carefully pollinated by hand, for only thus can a satisfactory crop be ensured. The illustration of one of Messrs. Sutton and Sons' houses of primulas portrays men engaged in this delicate operation, which occupies them day by day throughout the whole flowering period. It is to this hand pollination, combined with constant re-selection, that is due the possibility of obtaining true seed of special colours in primulas, gloxinias, cyclamen, etc. The work of the hybridist, too, is worthy of remark. Crossing and intercrossing of species and varieties of all classes of plants is carried on unceasingly with a view to the production of new and improved sorts, that add increased charm to the pursuit of gardening. The novelties we see and admire represent, in most cases, the careful and scientific labour of years, but only those who have themselves been plant breeders know how small is the proportion of that labour that can be shown to the world. Many crosses must be made, and many seedlings raised, but few shall be the gems among them.

The Actual Seed Farming

or production of seeds in bulk is, of course, entirely distinct from the trials to which reference has been made. The conditions most desirable for seed growing are a fairly light, well-drained soil, and a dry atmosphere. The county of Essex has attracted many growers, both soil and climate being particularly well adapted for the purpose. Anyone travelling on the main line of the Great Eastern Railway between London and Ipswich, or, better still, by motor along the roads in Essex and Suffolk, during the summer months will see great fields aglow with a great variety of annuals, and also vegetable crops for seed. Of late years sweet peas have been largely grown for seed in Essex, and this county has also for many years produced a large proportion of the seeds of scarlet runner and kidney beans. In Suffolk and Norfolk also much swede and mangold seed is grown, as well as oats and barley. Lincolnshire and Cambridge, as is well known, are great potato-producing counties, although Scotch and Irish-grown seed potatoes are held in highest esteem. Perthshire and the Lothians are centres of the potato industry, the growers from these districts annually coming down in strong force to Smithfield Show, where buyers of seed potatoes are wont to foregather to inspect the samples and place their season's orders. The moist climate of Ireland militates against the ripening of many seeds, and, consequently, potatoes constitute her chief output in this direction, although a quantity of linseed is produced in connection with the cultivation of flax for the linen industry.

For many years Oxfordshire was famous for onion seed, but, apart from a few private gardens and farms where seed is still grown on contract, the growth of onion seed seems to have drifted away, partly to Leicestershire, and partly to the South of England. The excellent illustration of a field of onions growing for seed, kindly supplied by Messrs. Harrison and Sons, Leicester, shows a remarkably fine crop, and it may be remarked that many an equally productive field of garden peas for seed has been seen in this county. There are well-known seed farms around Wordsley, Worcestershire, and even as far north as Carlisle and Darlington, whilst sweet peas have for many years been extensively grown for seed at Wem, in Shropshire, and in Somerset also a good deal is done in this way. The exact spot likely to be suitable for a seed farm depends, not upon the fertility of the soil, so much as dryness. What is necessary is a short season of rapid growth, resulting in early maturity, for if growth is maintained until late summer there is small chance of ripening a satisfactory crop of seed.

Of the routine work of weighing, measuring, packeting, and packing orders it is unnecessary to write, except to remark that in the case of seeds to be sent to distant lands, especially those that cross the Equator, special precautions have to be taken to ensure safe transit. The seeds are first treated in a heated chamber, in order that moisture, which during transit through tropical climates would set up germination, may be removed. Tinfoil packets and hermetically sealed cases are used to ensure safe transit.

My concluding word is to youths embarking on a horticultural career. It is, in my opinion, highly desirable that anyone whose ambition it is to make his mark in horticulture should spend a year or two in a really good seed establishment, and, notwithstanding the oft-made assertion that horticulture affords meagre return for much study and labour, the belief is held by myself that there is plenty of room and possibilities, especially in this branch of the profession, for men of enterprise and ability. A. J. MACSELF.

A FIELD OF ONIONS PRODUCING A FINE CROP OF SEEDS.

GARRYA ELLIPTICA.

This handsome Californian shrub is parcularly attractive in the dark days of the year, the male plant, with its long greyish-white catkins, being especially effective. Though a native of California, it may be treated as practically a hardy shrub, since it succeeds without protection in bush form as far north as Edinburgh, Stirling, and Kirkcudbright. In the colder districts it is often to be seen trained against a wall, but such protection is quite unnecessary, as it will form a fine and symmetrical shrub in the open ground.

Unfortunately, the mania for training subjects of non-scandent growth to walls has led to many beautiful things in the way of flowering shrubs, that are perfectly capable of enduring our winters in the open, being deprived of the free and natural loveliness that they display when permitted to assume their rightful proportions and habit of growth. However, where there is ample wall space in the colder localities there is no reason why the garrya should not be afforded a portion of the wall surface, as it is a striking subject and quite unique from the usual occupants of walls. When pruning is required this should be taken in hand immediately the flowering is past.

In the south-west it attains large dimensions, sometimes reaching a height of 15ft. and a like diameter. Large bushes, when thickly set with innumerable catkins, many of which are over a foot in length, form in the winter season objects of remarkable beauty and retain their attractiveness for many months. A valuable characteristic of this shrub is that it will accommodate itself to almost every description of soil and environment, and will produce its catkins as freely on a steep bank of rubble that is dust-dry in the summer, as on a level surface of rich, prepared soil, though its growth will naturally not be so vigorous. In partially-shaded positions it will also succeed, and in such may be seen bearing numerous tassels, so that there are few situations for which it is unsuited. For seaside gardens it is also very useful. Even in that death-trap for tender subjects, the mixed shrubbery, it will hold its own better than most things.

Intending planters should not therefore be deterred by any doubt concerning the hardiness of Garrya elliptica from planting it in such positions as they may have at their disposal, for as a decorative, evergreen shrub it is one that, from its hardihood and ornamental qualities, can hold its own with any of the more decorative denizens of the pleasure-ground.

WYNDHAM FITZHERBERT.

Clarkias. — The clarkias, especially Elegans, Scarlet Beauty, Double Salmon, and Delicate Pink, are quite as beautiful, and probably more useful, than the schizanthuses for pot culture. They are valuable for cutting, and are highly esteemed in the dwelling. They require much the same treatment as the schizanthuses, except that they will need "stopping" once or twice to encourage a bushy habit. A light fumigation with a nicotine compound occasionally will keep them clear of aphis.—E. HARRISS.

Cotoneaster rotundifolia.—In the bright colour of its berries and the profusion in which they are borne, this cotoneaster stands in the very front rank of the members of this highly ornamental genus of hardy shrubs. It also possesses another very desirable quality, and that is the berries are far less attractive to birds than some of the others, so that they retain their ornamental feature over a lengthened period. —W.

SOPHRONITIS GRANDIFLORA.

This is a lovely little orchid that resembles a very diminutive cattleya in appearance, and was at one time called Cattleya coccinea. The plant blooms during the winter, and is the finest species of the genus, the flowers lasting six weeks or more in perfection, and are so large, compared with the tiny pseudo-bulbs, that one wonders how these could possibly produce and carry them for so long.

The amount of bloom produced by healthy specimens of this orchid is truly remarkable, and the glowing scarlet colour never fails to excite admiration.

This little epiphyte thrives best in shallow pans or baskets suspended from the roof rafters, and succeeds well under cool treatment. It should be afforded a light position, but never be exposed to bright sunshine. The plants grow freely in a compost consisting of equal parts of osmunda fibre, polypodium fibre, and sphagnum moss, putting in plenty of drainage beneath it, and fixing the roots firmly in the material.

SOPHRONITIS GRANDIFLORA.

A finely-flowered specimen of this handsome scarlet-flowered species in the Westonbirt collection.

Repotting, when necessary, should be done soon after the flowering period, as new roots are then being produced from the partially developed growths. In the matter of watering, especial care is very necessary, as the small, growing roots are easily injured by drought or excess of moisture.

H. G. ALEXANDER.

Westonbirt Gardens.

Propagation of Seakale.—To obtain crowns for next season's supply, it is an advantage to prepare the thongs at an early date. For this purpose select strong and quite clean root thongs, any showing signs of black rot should be burnt. The sets should be six to seven inches long. Cut the top square and the base diagonally, this prevents confusion as to which is the growing end. Tie up in bundles, and stand them upright thickly together in boxes, and work finely-sifted soil amongst them, water them in, and place in a structure where frost is excluded.—W. MESSENGER.

INDIAN AZALEAS.

We have seen several changes in the popularity of different plants within the last twenty years or so, but Indian azaleas are still largely grown. True, the large, stiffly-trained specimens have practically disappeared, and the smaller pyramids are not met with to any great extent. On the other hand, standard plants are a good deal in vogue, not the stiff, formal standards, but plants in which the head is, to a great extent, allowed to assume its natural habit. Most of the plants are, however, as of old, grafted on to stems six to nine inches in height, in which way they form useful specimens for placing in vases and for other like purposes. Of late years quite an extensive business has been done among the small-flowered kinds grown as neat bushy little plants on their own roots and confined to small pots.

A notable feature of the azaleas of the present day is the increased popularity of the different varieties in which the flowers are of some shade of salmon-rose, with a light centre and margin, and for the most part with the edges of the petals crisped. Many of these are of a semi-double character. Among varieties of this class may be mentioned Haerensiana, Sir J. T. D. Llewelyn, President Oswald de Kerchove, Professor Wolters, Schryveriana, and Vervæneana. Two old and for many years popular varieties—Madame Camille Van Langenhove and Madame Van der Cruyssen—are now, comparatively speaking, very little grown. The magenta tinge in the rose-coloured blossoms of the last-named is not at all fashionable.

Of white-flowered kinds, the semi-double Deutsche Perle, for early blooming, and Niobe, for late, still remain about the best. Self scarlets or reds are always in demand, among the best of these being Apollo, Spitfire, and Vuystekeana.

Whatever effect the wet summer of 1912 had on some classes of plants, it would appear to have been particularly favourable for azaleas; at all events, the plants that are being sold in such large numbers are in a very good condition, and well set with flower buds.

W. T.

CAN BLACK CURRANTS BE SAVED?

I ask the above question quite seriously, because, as many other people must have done, I have watched the steady march of the demon mite or big bud for the past twenty years until now it has found its way into every country, every parish, and nearly every garden in the country. I recall the days when big bud was almost unknown, when meetings were held in currant-growing districts to discuss it, and when practical fruit growers put down the swelling of the buds to mild climatic conditions and fondly thought that these abnormal specimens were going to give them good bunches of fruit. That period of ignorance has passed away; there are few growers who do not know to their cost the meaning of the swollen buds, and one thinks with regret of the many acres of once profitable bushes that have been grubbed up and burnt owing to the ravages of the pest in question.

There is no gainsaying the fact that the black currant is a popular fruit, and, on the whole, barring the big bud, it is a lucrative crop to grow, but the time has arrived for looking facts in regard to it straight in the face, and, though I do not wish to take a too pessimistic view, I think there are good grounds for asserting that the future of the black currant as a commercial crop is threatened, and the possibility of it going out of cultivation as such certainly exists. We can see what has been done, how many acres of land, once under black currants, are now devoted to other crops, and the wholesome fear that growers have about planting this fruit, in the first place because they do not know where they can buy clean bushes, and secondly, because even if they were fortunate in this respect, they do not know how long they will remain free from the pest after they have planted them.

And while the big bud has been spreading, spreading, spreading, what has been done in the matter of prevention or eradication? Very little, I am afraid; and while the scientist has been able to render very little assistance to the practical man, the distribution of infested bushes has gone on unchecked, and the puny efforts that have been made to deal with the trouble have led to nothing very definite. Whether the position now is one of locking the stable door after the horse is stolen is an open question, but if there is a possibility of saving the black currant from sheer destruction, surely the time has come to set about it. Money is now being distributed from the Development Fund to assist horticulture. Research stations are being established for dealing with the knotty problems of the fruit-grower: pathologists, mycologists, and other "ists" are being appointed, and let us hope that among them they will be able to discover some practical scheme for eradicating or checking this scourge, and providing means by which growers may plant black currants without fear and trembling.

Are there any means open to that end? I put the question, and add another: Is there any variety of black currant immune from big bud? We are reminded here of varieties that have been sent out with that reputation, Boskoop Giant to wit, which when it first appeared was bought and planted in the hope that it would grow free from big bud, but, of course, in this respect it has proved a hopeless failure. It has been observed that black currants which produce hard red buds do not suffer so badly through mite as those which bear soft green buds, and many of us know old-fashioned black currants growing in cottage gardens where they have stood for years, and a big bud is never seen on them, though bushes of better varieties in point of the size and character of the fruit, planted close at hand, are absolutely infested with the pest Surely it is better to grow a variety that is not so fine if it is proof against big bud, than plant the very best in cultivation if it is practically certain that in a few years the bushes will have to be consigned to the fire heap.

Why not test this point thoroughly, and in order to do it, I am inclined to think that one big central national fruit station, managed, say, under the auspices of the horticultural section of the Board of Agriculture, would be better than giving grants for placing more or less miniature places in different parts of the country, for after all, what may be described as microscopic experiments are not of much commercial value. This problem of the black currant is one of national importance: then why not devote public money to it, by collecting every known variety of black currant and growing them together, not an odd bush or two of each, but in sufficient quantity to prove once and for all which, if any, are proof against the bud mite. These statements that are made to the effect that such and such a variety is not so liable, and another is immune, are not good enough; we want proofs, definite proofs, and these can only be obtained by experiments on a comprehensive scale.

And while varieties were being tested, could not other means be tried on a sufficiently large scale to demonstrate to growers whether or not the big bud can be eradicated and prevented from spreading further? We have had remedies suggested that were of quite an unpractical character, we have others before us that, on the other hand, are thoroughly practical if they are reliable, but few people seem to try them because there seems to be a rooted conviction in the minds of many growers that the case is hopeless, and there is no cure for big bud. Surely the thing might be tested on a big scale by disinterested persons for the benefit of fruit growers as a whole.

A few years ago Professor W. E. Collinge suggested a remedy in the shape of dusting the bushes with lime and sulphur, but one does not see many people using it, and I am afraid, in the matter of fruit pests, that the tendency is to drift from one remedy to another without sticking long enough to any single means of eradication. While the conviction seems to be growing that there is no remedy for big bud we have Messrs. J. R. Pearson and Sons, of Lowdham, Notts, openly stating in their catalogue that it can be easily eradicated by simply spraying the bushes with soft soap and quassia solution. I hold no brief for the Messrs. Pearson, but they are admitted authorities on fruit culture; they have a reputation to lose, but nothing to gain in the matter, as soft soap and quassia is not a proprietary insecticide, and it is not likely that the firm would make the statement in public unless they were prepared to substantiate it. Considering that the solution is about as cheap an insecticide as anyone could get, and that the labour is the only real item of expense, the wonder is, on the face of the evidence, that every black currant grower in the country does not try it. They cannot, of course, be made to do it, but the remedy might be tested at an official experimental station, the results could be published, and if thoroughly satisfactory the question might then be considered of making the spraying of infested black currants compulsory with a view to wiping out the pest.

This is no new idea of Messrs. J. R. Pearson and Sons; they have been at it for years, they are convinced about it, and it is all so simple, for in respect of severe attacks the firm says that the bushes should be sprayed at intervals of a week or ten days from the end of March to the first week in June; even then it may not be possible to kill every mite the first season, but a second season should make the plantation free. It is further advised that after spraying, as recommended above, the bushes should be looked over after the leaves have fallen. Any big buds that may be seen should be picked off, and a top-dressing of manure be given.

There you have the whole thing in a nutshell, and the moment is opportune for mentioning it, because March will soon be here. I need hardly say that any who adopt this simple remedy should give it a fair trial; do it thoroughly and consistently, not spray the bushes twice and forget all about it, but carry out the instructions to the letter.

Perhaps I began this article somewhat pessimistically, but the general state of affairs round about is my excuse for doing so, but if we accept Messrs. Pearson's evidence, and I know of no reason why we should not, then it will be a standing disgrace to the fruit growers of this country, both commercial and amateur, if black currants are allowed to drop further out of cultivation than is the case at present, while there is a simple and available remedy within the reach of everybody. H.

Rhododendron parvifolium.—This hardy rhododendron is related to the better known R. dauricum, and, like that species, it flowers in mid-winter. It is of a dwarf, freely-branched habit of growth, clothed with small pointed leaves; while the flowers, which are of a rosy-purple colour, are borne in compact clusters. Though quite hardy, the expanded blossoms are liable to be cut by sharp frosts, hence it should, if possible, be planted in a sheltered spot.—K.

Tetratheca thymifolia. — The tetrathecas are a very pretty class of free-flowering shrubs, natives of Australia. They are all of a dwarf twiggy habit of growth, and are sometimes known by the generic name of Tremandra. Being what are popularly termed New Holland or hard-wooded plants, they require practically the same treatment as the greenhouse heaths, epacris, and others of this class. The tetrathecas often flower in spring and early summer, and, though this species is in the "Dictionary of Gardening" said to flower in July, it has been in bloom during the whole of the present winter. It forms a dense, bushy, little specimen, about a foot in height, and the small mauve-purple flowers, with dark-coloured anthers, are borne in great profusion.—T.

ANEMONE-FLOWERED CHRYSANTHEMUM.

During the past few years, say, from ten to fifteen, the anemone chrysanthemums have been looked upon more or less in the light of things that are past; this, I presume, being owing to the ever-increasing numbers and the popularity of the single varieties. Within the past two seasons there has been a decided tendency in certain quarters (particularly among the older members of the National Chrysanthemum Society) to try and resuscitate them somewhat, not because they are more beautiful than the singles, but more likely to prevent any section or type of the flower going entirely out of cultivation. For this reason it is commendable, for it must be borne in mind that the anemone-flowered chrysanthemum some twenty years ago was quite popular as an exhibition flower.

I can hardly think that they will ever become so popular again, for the few boards that are occasionally seen at the shows are, as a rule, rough and unfinished, and in such a state there is nothing to recommend them, but, as decorative subjects, there is still hope, and probably room, for them: and, although it is a long time ago now, I have still in my mind some very fine plants grown for decorative purposes, pot plants, not with a few straggly flowers, but from which one could cut a good sheaf of bloom from each plant.

Unfortunately, among this section there were a good many varieties that were of rather an undecided shade of colour, and, as these were not pretty, they very quickly fell into disrepute. A few of the better varieties that I remember were Madame Chas. Leboscqz, yellow; Fleur de Marie, white (fine for decorative purposes); Lady Margaret, white; Descartes, bright crimson; Junon, pink; Thorpe, Jun., yellow; W. W. Astor, pink; Delaware, cream; and Mrs. Harry Eland, lilac. These, if exhibited in good form, say, five or six blooms in a vase similar to the one illustrated, could not fail to be much more attractive than the older method of showing them flat on boards, and in this way they might easily hold their own against some of the singles. The above-mentioned are termed the Japanese anemones from their larger size and longer florets, but the smaller, and, to my mind, more effective Pompon anemone varieties are the ones that are more likely to prove useful, and for table decoration and small vase work generally they provide a very nice change to the more regular-petalled singles and Japanese. Antonius, Emily Rowbottom, and Marie Stuart are three varieties that all lovers of chrysanthemums might grow with advantage.

Kathleen May, introduced by Mr. H. J. Jones some three or four years ago, proved the forerunner of a new type of anemone single, which may become popular. This variety—crimson petals with yellow cushion—is among the best of our late decorative varieties, and, although a somewhat tall grower, it carries a good crop of bloom, which lasts well over Christmas. Following on this we have Godfrey's Perfection, a white variety, much shorter in growth, and for this reason makes a very nice pot plant. A still later introduction is Snow Queen, from Messrs. Cragg, Harrison, and Cragg, and, as its name denotes, it is a most beautiful flower of snowy whiteness which will be in much demand, so that, if our friends are not able to rejuvenate the old type of anemone, there is every likelihood of this newer type finding a place in popular favour.

THOMAS STEVENSON.

IXORA SALICIFOLIA.

One of the most graceful of all ixoras, and one not often met with, is I. salicifolia: its willow-like foliage and free habit of growth should go far to make it a favourite. The greatest recommendation is its beautiful trusses of flower, in colour a soft shade of orange-scarlet. The complaint is sometimes made that the flower trusses of an ixora are too formal, and perhaps in these days of cut flower and floral decoration there is some ground for this complaint, but formality either of habit or flower cannot be urged against the species under notice, for the flowers are much more thinly arranged in the trusses than in any other ixora, and consequently possess much grace, while the habit of the plant is light, as the specific name implies. This species succeeds better when grafted than on its own roots, the best stock being I. Duffi, although both I. coccinea and I. javanica answer the purpose very well; the grafts, as a rule, "take" very easily, and will soon make nice plants.

There is no doubt that Ixora salicifolia requires rather different treatment to the majority of ixoras; like I. Duffi, it grows very freely and quickly, and thus some difficulty is experienced in obtaining flower trusses. It should be kept growing through the autumn and winter months, but for a few weeks during the early part of the spring, commencing at the end of February or the beginning of March, it should be rested, to use a more or less analogous term. It must not be "rested" in the ordinary sense of the term, but must receive just enough water to keep it growing and no more, thus causing the growths to "harden," and to set their flower trusses. Previous to this the growths will have been thinned out, leaving the stronger ones.

This species will not submit to hard pruning, but when the plants have finished flowering the shoots may be shortened back a very little, or in some cases just pinching out the decayed trusses of bloom will be sufficient to induce the plants to "break" and produce new shoots. As is the case with some other ixoras, I. salicifolia prefers a higher temperature than the majority of the species, and it has been found to thrive when treated identically with I. Duffi and I. coccinea, these two being undeniably partial to more heat than the other members of the genus. A winter temperature of 70 degrees, rising in the day to 75 or 80 degrees, will not be too high, while in the summer the night temperature should not fall below 75 degrees with a rise on sunny days to 85 degrees, and even 90 degrees; a still higher temperature will not be detrimental to success.

Cheltenham RALPH E. ARNOLD.

CHRYSANTHEMUM MRS. H. ELAND.

A distinct and beautiful large-flowered anemone, of a pleasing lilac colour.

ANTIRRHINUMS IN 1913.

Horticulturists generally are expecting much from the year 1913. The general idea is that great progress will be made, and progress at a more rapid rate than ever before. The year 1912 was one of all-round progress, with the great International Exhibition as its outstanding feature.

The race for novelties still continues, and many groups of plants have come into greater prominence than ever they have achieved before. This is partly due to the splendid enthusiasm that horticulturists put into their work. The raising of new varieties, the careful selection of stocks, and the pushful advertising of specialities, all show the keen interest that the modern grower takes in his work.

Among popular subjects antirrhinums now rank as one of the foremost groups of plants for garden decoration, and, in my opinion, 1913 will be a great antirrhinum year. Many things point to this. There is the wealth of splendid new varieties which the specialists are offering. There are the coming antirrhinum trials at Wisley. There are the memory pictures of antirrhinum displays in some of the larger gardens during 1911 and 1912, and at some exhibitions. Lastly, there is the prominence which writers are beginning to bestow upon antirrhinum subjects.

From seeds sown in February and March plants can be raised which will flower from June until November. A host of sterling varieties are procurable from the seedsmen, and a careful selection of these will give the finest results. Varieties that are not quite fixed, or which one has but little stock of, can be easily propagated from cuttings. These can be rooted at almost any period, provided one can obtain the necessary soft side growths (not flower growths).

Seedlings raised from seeds sown late in February or quite early in March should be grown steadily for a time in an airy, comparatively cool house, and then hardened in the cold frames. Any coddling or overcrowding militates against success. The question of soil is not a pressing one, but I find that ofttimes the flowering season is prolonged when the antirrhinums are in a heavy retentive soil. Any manuring should be done when digging the ground some time previous to planting. Moderation should be the stern rule, and the use of artificials to "stimulate" growth I have hitherto found quite unnecessary.

It will be borne in mind that antirrhinums are usually divided into three sections, namely, the dwarf, or Tom Thumb varieties, the tall varieties, and the intermediate group, which, coming between the other two, is easily the most valuable of the three for general garden decoration.

Of these Flame is one of the latest comers, a bright orange-scarlet, which will prove very telling as a contrasting colour. Vesuvius is a bright orange, very attractive en masse, a variety with plenty of fire in it. Beacon, which the raisers describe as a cinnabar-scarlet, must also be reckoned with, and should be noted by all who are making large plantings.

Of the whites, The Bride, an absolutely pure snowy white, and Queen of the North, white with a sulphur lip to the blossoms, are about the best in commerce. Northern Lights comes midway between the two, and has an especially good habit.

Pink antirrhinums are a favourite section with me, and many good forms should soon come to light, which will carry them far in public estimation. Several are already in commerce. Venus is good, but belongs to the tall section, making it essentially a back-row plant. Rose Dorée is a soft salmon-rose, a decided acquisition, and Cottage Maid is a pale pink with white throat. Daphne gives a coral-rose shade relieved by white. Newer still is a selection of bushy narrow-foliaged forms, which are very light and graceful in habit. Marjorie, with tiny reddish-green leaves, and hosts of pale pink flowers, is a coming plant. Inspiration gives a lovely shade of rosy-pink, clear and effective. Iris is a shade paler, a soft delicate pink, otherwise very near to Inspiration in growth and foliage.

Some of the carmine and coral-red shades are worthy of note. Brilliant and Carmine Queen are but two out of several, but they are sufficient to show the value attaching to these shades.

Scarlet King, very near to scarlet, as antirrhinum colourings go; and King Alfred, a variety with deep orange and rose blossoms, are rich in hue, and with Defiance complete a trio which lovers of rich colours would do well to note.

Again, among the orange, salmon, and apricot hues, one obtains some warm, brilliant touches of colour which are a delight in the garden, especially when the days are on the wane. Bonfire and Orange King are among the number, both good attractive forms.

Yellows and crimsons we have had galore, and though such old-time colours one cannot omit them from the garden. Selected and perpetuated varieties are readily obtainable, and are usually absolutely true from seed. My list of varieties may seem lengthy, but only a tithe of them are given.

In conclusion I wish to say a word about position. It is usually stated that a sunny position is desirable, but this is not necessary, as the antirrhinums do exceedingly well in shady spots, provided they are not overhung by heavy trees. Try them in moderately good soil on a shady bank. The effect will surprise you, and the blossoms last longer than in full sunshine.

Many old favourites will doubtless be partially displaced this year—the Year of the Antirrhinum. P. S. HAYWARD.

Sweet Cherries.—Good varieties will be found in Elton Heart, Rivers' Early, Napoleon Bigarreau, Kentish Bigarreau, Waterloo Heart, Black Tartarian, May Duke, and Noble. When planting sweet cherries, see that the stations are thoroughly drained, and use good fibrous loam with plenty of lime rubble, burnt earth, and a little sweet, thoroughly decayed manure. Make the foundation on which to set the roots firm, trim the ends of all injured roots, keep the stems a reasonable distance from the walls to allow for swelling, and, after planting is finished, lay a little strawy manure over the roots, but do not nail or prune for a few weeks until the soil has settled.—H. MARKHAM.

ARE COLOUR SCHEMES A SUCCESS?

Advanced ideas regarding the arrangement of plants in such a way as to produce certain colour effects are not always successful, and usefulness is often lost sight of. Besides, Nature, to which we look for all our lessons, avoids the extremes sometimes aimed at, and teaches us to keep, as far as we can, from the mathematical blending of colours now so often advocated. Although this freak of fashion is even applied to trees and shrubs, it is chiefly with herbaceous plants that colour schemes for certain periods are essayed. In no instance have I known of a single success. The reason for this is not difficult to find, as all herbaceous plants cannot be induced to bloom at the same time.

A lady I met some time ago was anxious to secure a great display of bloom in her herbaceous borders during the month of July, but would only have them blended from white through all the colours to red, and then back to white again. The borders were about fifteen feet wide and although there was no difficulty in attaining the desired, but still artificial, effect in the front of the border with violas and other low-growing plants, few things were available for the back rows. In spite of this drawback the borders were planted in accordance with the owner's ideas, and the result was one nobody seemed anxious to copy.

Another colour scheme I saw some years ago, in a border about half the width of the one I have just referred to, proved such a failure in effect, and disappointment in quality of bloom for cutting purposes, that the whole of the plants, to the value of £13, were dug up and put on the rubbish heap. The border was then replanted in groups arranged with regard to colour, size, and time of flowering, so that a succession of bloom was maintained all over the border throughout the summer months. The plants employed in this instance were admirably adapted for supplying cut bloom for house decoration.

Since then my doubts about "colour schemes" being a success have induced me to go far, observe closely, and learn all I could, in order that I might see for myself the effects of various attempts, but so far I have not met with anything I would care to reproduce. I am now convinced that a really fine effect from a blended colour scheme is outside possibility on anything like a large scale, as the plants are not in existence for such a purpose.

The nearest attainment to anything like success was one in which annuals, biennials, and bedding plants formed a large part, and in this case some of the annuals were lost among the taller-growing things, giving the border a rather untidy appearance.

So far as herbaceous plants are concerned, the best effects can only be secured by arranging them in good-sized groups, with the taller-growing ones at the back, and the dwarfer ones at the front, of the border, and in the order of flowering, so that a succession of bloom is equally distributed over the border from early spring till late autumn. PEDESTRIAN.

Eupatorium vernale.—Compared with most of the greenhouse eupatoriums, this is of dwarf habit, hence it is well suited for growing in comparatively small pots. Good bushy examples in pots five or six inches in diameter, are very effective; and, what is more, they retain their beauty a considerable time. Being so easily propagated is another point in its favour.—W. T.

HANDSOME DECORATIVE PLANTS FROM SEED.—II.

Dracænas.

Cordyline (Dracæna) indivisa, one of our most useful green and bronze foliage plants, is of fairly rapid growth, making useful plants within eight or nine months from the time of sowing the seeds. The potting compost should consist of about two parts fibrous loam to one of peat, adding sufficient sharp gritty sand to keep the soil porous. When the plants are growing freely, and the pots becoming filled with roots, an abundance of water should be given. An intermediate or greenhouse temperature will meet their requirements.

Clerodendrons.

Clerodendron fallax is a very pretty and showy stove plant, of dwarf, erect habit, bearing terminal panicles of intense scarlet flowers all through the autumn and early winter months. Seeds should be sown early in the year in well-drained pots or pans containing a light rich soil; plunged in a hotbed, germination quickly follows, but care should be taken to keep the soil uniformly moist during that period, otherwise the seeds will germinate irregularly. Grow the young plants in a brisk heat with plenty of atmospheric moisture, but subsequently they may be gradually inured to a much lower temperature, and be given plenty of air during favourable weather; this treatment—not always followed—will ripen the growths, and the plants will produce much larger spikes of flowers than if given stove treatment the whole season through. After flowering the plants may be rested by withholding regular supplies of water, and by keeping them in a temperature of about 55 degrees until they are again started into growth for use the following season.

Exacums.

Exacum affine is a pretty dwarf greenhouse annual, producing numerous sweet-scented pale blue flowers, the plants remaining in bloom for a very considerable time. Growing singly in three-inch pots, or three plants in a five-inch pot, is the most serviceable method of culture. Over-potting must be scrupulously avoided. The growths may be stopped two or three times during their early stages of growth at each second joint, that is if dwarf and very compact specimens are required.

E. macranthum—a stove biennial—produces flowers considerably larger than E. affine, and of a very deep purple colour, with bright yellow stamens. Seeds of this should be sown as early in the year as possible, using a light rich peaty compost, and afterwards growing the young plants in a brisk moist heat.

The drainage for E. macranthum must be perfect, and the too frequent use of the water-pot avoided—both very essential matters if good healthy specimens are to be grown. A sharp look-out must be kept for insect pests, thrips and red spider especially, for if once the plants become unhealthy from their attacks they quickly succumb.

While the exacums are in flower a lower temperature may be allowed with impunity, so long as they are not over-watered. To have a group of E. macranthum in full bloom is an ample reward for the care necessary to grow it to perfection.

Gerberas.

Gerbera hybrids are plants of easy cultivation, and if grown in pots they make pleasing specimens for the greenhouse or conservatory. In warm localities, growing in a light rich soil, they make excellent plants for the outside borders, and flower freely, but as pot plants they are, in most instances, seen at their best. The plants produce numerous daisy-like flowers, borne on long wiry stalks, well above the foliage, which, by the way, is dwarf. Used as cut flowers they are highly decorative, and produce a light and pleasing effect.

The seeds should be sown in slight heat, and the plants grown in a temperature of about 60 degrees, allowing them plenty of light and sun. To in any way coddle the plants is to court failure, and should on no account be attempted. When fully established in their flowering pots they will withstand a very considerable amount of drought at the roots with impunity, and during the winter—or resting time—little or no water should be given.

Rehmannias.

Rehmannia angulata will flower freely within eight or nine months from the time the seed is sown. This plant is very decorative, and should be grown more frequently than it is, its cultivation being extremely simple. The flowers, rosy-purple in colour, with a yellow throat, spotted with purple, are from three to four inches in diameter, growing on a stem twenty-four to thirty-six inches in height, the latter varying according to the strength of the plant. As soon as the seedlings are in rough leaf ordinary greenhouse treatment may be given them. During the summer months, that is as soon as the plants are placed in their final pots, cool-frame treatment will be all that is necessary, exposing the plants on all favourable occasions to the full sunlight. As the flower spikes advance in growth remove to a cool greenhouse or conservatory.

R. Pink Perfection is a variety producing flowers of a clear bright pink colour, with a paler throat, and by some growers this is preferred to the type.

W. Hedley Warren.

Aston Clinton Gardens, Tring.

DIANTHUS HEDDEWIGI.

This is sometimes spoken of as a species, with the English name of Japanese pink, and sometimes as a variety of Dianthus chinensis (syn. sinensis), the latter being known as the Indian pink. The varieties of both are often classed under the latter term, and for the purposes of these notes we may regard Dianthus Heddewigi in its numerous forms as those most worth growing of this class of pinks. They are near relatives of the carnation (Dianthus caryophyllus) and the sweet william (D. barbatus), and most of the members of the family are plants of the heath, dry meadow, cliff, or alp. The Indian pink, like its relatives just mentioned, will not thrive in a soil which is too rich or too damp, unless accompanied by all the sunshine possible, showing its dislike to excess of moisture and deficiency of sun and air by rotting off near the base, or becoming very straggling and untidy.

These pinks are usually described as hardy annuals, though on dry soils they will sometimes last two or three years if the winters are not too severe. They may be sown in June or in the early spring, according as they are treated as biennials or annuals. In the former case, unless the soil and situation are very favourable, they should be grown in pots and kept in a cold frame or house during the winter, taking care to give plenty of air to prevent them damping off. Planted out in well-cultivated soil in late March or early April, blossom may be obtained early in June, and large clumps will be produced a foot or more in diameter, flowering continuing right through the summer if the dead flowers are picked off occasionally.

The main advantage of treating these pinks as biennials is earlier flowering, but they will not be much later in coming into bloom if seed is sown in gentle heat in February, and the seedlings treated like tender bedding annuals. They should be kept near the glass, and given plenty of air as they are not capable of enduring much coddling, and as soon after the middle of May as weather conditions permit they should be hardened off by being put in a cold house or frame. They may not be thought worth the trouble of potting off, but the results pay for it, the unchecked plants producing finer flowers and making stronger clumps, with less tendency to that straggling and weedy kind of growth which is rather characteristic to these pinks. Sturdiness and compactness of growth are encouraged by the soil being made firm before planting, and for this reason, too, no fresh manure should be added to the soil when the bed for them is prepared. Mortar rubbish, chalk, slaked lime, and basic slag are all good to mix with the soil if it is deficient in lime, or is of a very tenacious nature.

As bedding subjects, either for beds or borders, they are capable of very effective use, and offer considerable scope for the taste of the planter, both in the choice of colour and in the use to which they are put. At the same time, in an adverse season a bed devoted to them may be the one that suffers most, as they not only sustain more damage in rough weather than most things, but, as before mentioned, dampness spoils their habit of growth. Some object to the flatness presented by a bed of Dianthus Heddewigi, and those who do so will find them well adapted for use as a surfacing amongst those of taller growth, not just to fill up bare places amongst a bed of taller plants, or to cover the ground between greedy perennials on the borders, but to form the main part of a bed with tall plants set among them at a fair distance apart.

Some varieties grow a foot and a half high, but a good selection of both single and double forms may be obtained, which in a normal season will not exceed a foot in height. The colours range from white, through pink, salmon, and scarlet, to crimson, maroon, and brown, while some are laced and striped, flaked and mottled. If seed of a distinct colour is bought the grower must be prepared for some sports amongst them, and from seed of double varieties a certain percentage of singles, according to the quality of the seed. Some of the most dwarf varieties make good pot plants, but if cut flowers are desired the taller kinds should be grown. The flower stalks are thin and the flowers very light and graceful, which makes them especially valuable for small glasses on the dinner-table.

Alger Petts.

Salvia azurea grandiflora.—This is a most useful plant for late autumn flowering. Its long spikes of deep blue flowers make a striking contrast amongst chrysanthemums, which predominate in the conservatory during the late autumn months. When there are sufficient cuttings on the old plants (which are at present wintering in cold frames) they may be inserted in 4½in. pots, in a compost of two parts loam and one part leaf-soil, with a liberal sprinkling of coarse sand. Place five or six cuttings in each pot, and when the pots are full of roots shift them into 7in. pots in a rich soil. Some of the old plants may be shaken out and repotted if sufficient new stock cannot be obtained from cuttings.—E. Harriss.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

IMPORTED DENDROBIUMS. — Several species of deciduous dendrobiums have recently been distributed from importations reaching this country through the usual sources. For years I have drawn attention to the desirability of procuring plants of D. Wardianum in particular as early as possible in the season, as this gives them an opportunity of becoming plump and producing their new roots before the season becomes too far advanced. Our usual short summer seasons are not suitable for late importations. Dendrobiums are sun-loving plants, and we are enabled to obtain better results when growth can be so treated that it reaches maturity before the end of September. Once the deciduous dendrobiums lose their normal vigour it often takes a long time before they regain strength but more often than not they deteriorate. I have referred more especially to D. Wardianum above, because for private gardens there is none more useful. It is frequently subjected to the barbarous treatment of having the bulbs cut off at the base, when producing their flowers. This must naturally cause deterioration, because the new growth must depend largely for its sustenance on such bulbs, and one cannot expect to produce even a normal growth the next season. But even with rational treatment it will generally be found that the plants gradually lose some of their vigour after being grown under artificial conditions for a few years.

POTTING.—There are different ways of treating the plants after they reach us, and each may be carried out with equal prospects of success; but the first thing is to go carefully over the plants, cut away all dead and decaying matter about the pseudo-bulbs and roots, and carefully search for any insects pests that may have secreted themselves. After carefully cleaning them the plants may be either potted or placed in pans or baskets; afford plenty of drainage and a small amount of potting material. Place in a moist position in an intermediate house. No water need be given, but a little later the plants may have a slight spraying overhead on bright days. As soon as the new growths advance, and the young roots make their appearance, liberal treatment may be afforded. Some growers prefer, after cleaning the plants, to lay them out on a bed of ashes or sphagnum moss until such new growths appear; others will suspend them with the roots uppermost for a time, and, by syringing on favourable occasions, induce them to start before fixing them in pots. Personally, I believe in potting the plants as soon as they are received.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREEN-HOUSE.

SALVIA SPLENDENS.—Old plants which were placed in a light warm house after flowering should now be furnished with plenty of strong, healthy cuttings. These must now be taken off, and inserted in large 60-sized pots, in a light, sandy compost, placing about four cuttings in each pot. When rooted place them on a shelf near the glass in a moderately warm temperature until they are fit for potting. They may then be potted singly into large 60's, using a compost of loam, leaf-soil, and sand, and given the same position as before. This salvia is very subject to attacks of red-spider, but this can usually be kept in check by syringing them twice a day with tepid rain water. Should this pest obtain a footing dip the plants in an insecticide.

HUMEA ELEGANS.—These must be kept growing in a cool house near to the glass on a cool ash bottom. When the pots are full of roots they must be given their final shift into 8in. pots. Hastening the plants by forcing must not be attempted, as this would cause many of them to fail. Humeas require cool treatment at all times after the seedlings are once established in pots. Pot them fairly firm in a compost of fibrous loam, leaf-soil, lime-rubble, or charcoal, and coarse sand. They must be very carefully watered, and syringing at this stage should not be practised.

HYDRANGEA HORTENSIS. — Plants which were rooted last autumn from strong, well-ripened cuttings may now be started into growth with a reasonable chance of flowering. If they are not already in their flowering pots they must be potted at once; 48's will be large enough to flower them in. They require a fairly rich compost.

PRIMULAS.—Except when these are doing duty in the dwelling, they must be liberally watered with stimulants. With careful treatment they may be encouraged to flower for some time. During bright spells of sunshine the blinds on the house should be lowered.

CYCLAMEN.—Plants which are flowering may be given much the same treatment as primulas. Be careful when applying water not to wet the top of the crowns. Remove dead flowers by pulling them out from the base. Plants which are required for producing seed should be removed to a shelf near the glass. When the seeds are developing plenty of stimulants must be given. Young plants raised from seed in the autumn must be kept growing steadily in a temperature of 60 or 65 degrees. They will be the better if the pots are plunged in ashes or cocoanut-fibre. Apply water carefully and syringe them two or three times a day with tepid rain water.—E. HARRISS, Lockinge Gardens.

HARDY FRUITS.

PEACH AND NECTARINE TREES.—The pruning and training of these may now be taken in hand and pushed forward, so that the work is made complete before the buds become too advanced. In some gardens the branches are removed from the walls entirely for several weeks, so as to retard the buds as much as possible, and the training is left until very late in the season. I like to get all this work finished as early in the present month as the weather will allow. Where large trees have been carefully attended to during the growing season, not much pruning will be required, with the exception of removing shoots that have borne fruits, and are not required for further extension. Aim as far as possible at keeping the walls clothed from the bottom to the top with healthy, well-matured wood. It is not necessary to take down the whole of the trees annually, but a careful examination should be made of all ties and shreds lest any have become too tight to allow of swelling. If the main branches are infested with scale wash them well with a solution of nicotine or some other approved insecticide. Having put the trees in order, give every particle of wood and shoots (some fine morning) a good syringing with soap-suds and sulphur, Abol, or some other safe insecticide, not strong enough to injure the buds. Young and late planted trees may be left for some time to allow the new soil to sink. Any further planting to be done may be successfully carried on till the end of March; but see that the drainage is perfect, and use a sweet, moderately heavy, fibrous loam, with old mortar, charred earth, and a little thoroughly decayed manure added, and keep the main stems about four inches away from the walls to allow for thickening, and do not bury the roots too deeply.

GOOSEBERRIES.—If these have not been already pruned the work should be proceeded with; thin the heads to avoid overcrowding, and to secure good size of the individual berries. Shorten all long growths if required, and spur the inner growths back to a couple of buds. After pruning clear away the pieces, and rake some of the old soil from beneath the bushes, take it away to the rubbish heap, then dress the trees well with lime and soot, and top-dress with sweet loam and manure to encourage strong, fruitful growth and heavy crops of large berries. If birds prove destructive to the buds, place a few light stakes along the side of the beds, and amongst the bushes, and string black cotton from the stakes at different heights.

PROTECTION, ETC.—See that all protecting materials are ready for use, so that everything can be put up and the blossom and buds made safe when frosty weather comes. Apricots are amongst the first fruits to bloom, and should receive early attention, as the buds are frequently damaged before they show signs of bursting open.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

RHUBARB.—To maintain a continuous supply it may be necessary to lift and place in the mushroom house or other suitable quarters a batch of rhubarb roots. From now, by covering the crowns with tubs or boxes, and covering these with fermenting material, which should be so composed that a steady, mild heat is maintained, a successional crop will be secured. For further continuation it is a good plan to place ordinary hurdles on either side of the rows, and cover them with bracken or clean straw. A portion of the stock of roots should be replanted each year, and if it be deemed advisable the position of the bed should be altered; the crowns of forced roots can be used for this purpose, failing these lift the required number of stools, and divide them from the beds. The ground should be well manured and trenched; plant the pieces, each with a good bud, four feet apart for such varieties as Champagne, while later and stronger growing sorts should be five feet apart. The Sutton is a very fine variety, and is generally esteemed. If not already done, apply a good coating of well-rotted manure to established plantations and point it in.

PARSNIPS.—Towards the end of the present month a sowing of seed should be made, providing the ground is in a suitable condition. The site selected is usually one previously occupied by celery, and no better quarters may be wished for; if well roughed up as the celery is lifted it will only be necessary to fork over the ground, level inequalities, and work in a good dressing of soot. Sow a small pinch of seed in patches a foot apart, allowing fifteen inches between the rows for the Student type.

MINT, TARRAGON, AND CHIVES.—Continue to lift roots and place them in pots or boxes in gentle heat. If the stock of tarragon is short, by taking cuttings from the stools when about two inches long and inserting them in light, sandy compost in boxes or small 60-size pots, the stock may be readily increased. Afford gentle heat until the cuttings are rooted.

SEAKALE.—Where forcing operations are carried out on open quarters (a method I consider preferable to lifting and placing the roots in heat), care must be exercised that the fermenting materials do not become too hot; it only requires a very gentle heat to excite the crowns into growth. As the cutting proceeds remove the pots to fresh crowns, and cover as before, adding, if necessary, a little fresh material to start fermentation.—W. MESSENGER, Woolverstone Park Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The meeting held at Vincent Square on Tuesday, was, on the whole, an interesting one. The hall was well filled, and the attendance was good. Forced shrubs were a good feature, and early spring flowers were prominent. Many of the exhibits of hardy plants were, however, monotonous; indeed, one wonders why some of them were brought, as they could not have done any good to the firms they represented. Orchids, carnations, greenhouse plants, apples, and vegetables were all on view. Novelties were fewer than usual, even among the orchids.

FLORAL COMMITTEE.

Messrs. Allwood Brothers, Wivelsfield, Haywards Heath, contributed stands of capital blooms of Mary Allwood, Wivelsfield White, Le Rayonnante, Scarlet Glow, and Mrs. Crook perpetual carnations. A bold group of perpetual carnations from Messrs. William Cutbush and Son, Highgate, was well arranged, the cut flowers being disposed in large vases and stands around a small group of flowering plants in pots. Mrs. L. Mackinnon, White Enchantress, King Manuel (salmon-pink), Mrs. Tatton, and R. F. Felton were the most prominent varieties exhibited.

Perpetual carnations were displayed in quantity by Messrs. Stuart Low and Co., but the exhibit was scarcely so pretty as usual, the foreground being somewhat bare. The most important varieties were Rose Enchantress, St. Nicholas, Cinnabar, Baroness de Brienen, Fairmount, Carola, and Fire Glow. The same firm exhibited fine strains of cyclamen. Mr. C. Engelmann, Saffron Walden, set up a very fine exhibit of perpetual carnations included good flowers of Scarlet asparagus sprays; Sunstar, Mrs. C. W. Ward, Carola, Lady Northcliffe, Elektra, Rosette, and Fanny were finely represented.

Messrs. W. Wells and Co.'s perpetual carnations included good flowers of Scarlet Glow, Triumph, Northport, and Benora. Messrs. Young and Co., Cheltenham, brought up carnations, and their leading varieties were May Day, Mrs. C. W. Ward, Scarlet Glow, Mrs. Greswolde Williams, Duchess of Devonshire, and Hon. Lady Neild.

Mr. H. Burnett brought over some fine carnations from Guernsey, and of exceptional size and colour were the vases of Benora, R. F. Felton, Lady Northcliffe, Marmion, Triumph, Mrs. C. F. Raphael, White Chief, and Scarlet Glow.

Hardy flowers were very largely shown. Messrs. G. and A. Clark, Dover, presented batches of coloured primroses, a few hardy cyclamen, and small junipers, yews, and cupressus, suitable for rock gardens. Messrs. Whitelegg and Page, Chislehurst, brought up a few alpines, scillas, early narcissi, and Iris reticulata. Mr. G. Reuthe, Keston, displayed a collection of saxifragas, Iris reticulata, I. r. Krelagei, early rhododendrons, hepaticas, crocuses, hardy heaths, snowdrops, cyclamens, and many other interesting and beautiful things. Mr. Clarence Elliott, Six Hills Nursery, Stevenage, arranged a little rock garden, with pigmy abies, junipers, and retinosporus, and little colonies of Morisia hypogæa, Saxifraga sancta, S. Burseriana, and Eranthis cilicicus, the latter very pretty.

A very bright exhibit from Mr. Maurice Prichard, Christchurch, contained a very beautiful lot of Primula denticulata, P. d. rosea, and P. d. alba, oriental hellebores, Anemone fulgens, Soldanella alpina, Erica carnea, Saxifraga sancta, S. oppositifolia, etc., etc. Messrs. J. Piper and Son, Bayswater and Barnes, put up a quite substantial rock garden, and filled it with pigmy shrubs, double hepaticas, Morisia hypogæa, Saxifraga scardica, S. Burseriana, Primula Winteri, etc.

A charming arrangement of early spring flowers from Messrs. Barr and Sons, Covent Garden, attracted considerable attention. Associated with a little rockwork the firm had grouped Crocus Imperati, C. Cloth of Silver, C. Korolkowi, C. Sieberi, Cyclamen Coum, C. ibericum, Narcissus cyclamineus, snowdrops, gentians, etc. In pots the same firm displayed a few early daffodils and tulips, and gerbera flowers. Messrs. Wallace and Co., Colchester, had a quite pretty group of choice early flowers, backed by Prunus triloba, and Rhododendron præcox, Iris orchioides cærulea, I. reticulata, I. r. Krelagei, Crocus Susianus, C. Sieberi, C. aureus, C. biflorus, Fritillaria Chitralensis, F. citrina, and Erica mediterranea were a few of the leading subjects displayed.

Messrs. T. S. Ware, Feltham, contributed alpine plants and early flowers, but the most conspicuous feature of their display was the batch of fringed hydrangeas, the varieties Madame Emile Mouillere, and Mdlle. Renee Gaillard being represented by fine heads of bloom.

Messrs. J. Peed and Sons, West Norwood, contributed alpines, and the Wargrave Plant Farm, Lim., The Arcade, Liverpool Street, E.C., made up a little rock garden with a pleasing collection of alpines. Messrs. Thomson and Charman, Bushey, had a small rock garden, and Mr. James Box, Haywards Heath, filled one corner of the hall with a rock garden, furnished with groups of crocuses, primroses, Primula malacoides, P. denticulata, hellebores, Iris reticulata, etc., and a backing of flowering azaleas and spiræas.

A fairly large rock garden exhibit from Messrs. J. Cheal and Sons, Crawley, included a selection of evergreen and flowering shrubs of lowly growth, and colonies of Primula denticulata alba, Gentiana acaulis, Iris reticulata, erythroniums, hepaticas, saxifragas, primroses, etc. Mr. L. R. Russell, Richmond, submitted flowering shrubs in some quantity, showing Indian and mollis azaleas freely, with spiræas, wistarias, lilacs, and pyruses.

Camellias from Messrs. Wm. Paul and Son, Waltham Cross, attracted attention, and the single varieties—Tricolor, Waltham Glory, Mars, Juno, Minerva, and The Swan—were the chief attraction. A dozen or two bushes of the double white-flowered peach filled the centre of the group. Mr. J. Macdonald, Harpenden, showed grasses suitable for lawn making on various soils, and also exhibited lawn grass growing on prepared canvas in such a way that it could be laid down to form a lawn, and provide a good sward in a very short time.

Adiantums, davallias, nephrolepis, and a lovely lot of exquisitely beautiful filmy ferns, with their translucent fronds, were grouped with Polypodium irioides pendulum grandiceps (F.C.C.), selaginellas, etc., by Messrs. H. B. May and Sons, Edmonton. Forced viburnums, mollis azaleas, magnolias, Prunus triloba, choisyas, etc., were displayed by Messrs. W. Cutbush and Son, Highgate, and with these were associated beautiful groups of Iris reticulata, I. r. Krelagei, I. Danfordiæ, hepaticas, saxifragas, hellebores, etc.

Messrs. Rogers and Son, Southampton, had the carmine-red flowered fuchsia Benita on view; the flowers are rather small, but very freely produced. Messrs. H. Cannell and Sons, Swanley, were represented by cinerarias and cyclamens. A beautiful lot of blooms of Richmond roses, of lovely form and colour, were very greatly admired; these were shown by Messrs. J. Mount and Sons, Canterbury.

Coral Pink primula and Coral Pink Star primula, both shown by Messrs. Sutton and Sons, were much admired, as in each case the delicate salmon-pink tinting of the flowers was very charming.

A large and exceptionally bright group of forced flowering shrubs, arranged by Messrs. R. and G. Cuthbert, Southgate, attracted a great deal of attention. The centre was filled with Magnolia speciosa and M. s. alba, flanked by fine masses of orange, yellow, and pink mollis azaleas, standards of Prunus triloba, Forsythia suspensa, wistarias, and lilacs. The latter were freely used, with Pyrus malus atrosanguinea and P. Scheideckeri in dwarf form at either end of the group. Japanese maples, grevillias, and an edging of euryas and ferns lent the necessary greenery to the brilliant colouring of the flowers. Messrs. R. Gill and Sons, Falmouth, brought up a collection of Himalayan rhododendrons the trusses very full and bright; the new Primula Winteri was well shown.

A large group of greenhouse-flowering plants from Messrs. Jas. Veitch and Sons, Chelsea, contained fine batches of Indian azaleas, freesias, cyclamen, the white-flowered Kalanchoe Dyeri, Otaheite oranges, and lily of the valley.

ORCHID COMMITTEE.

From Messrs. Sander and Sons, St. Albans, came Pleurothallis cardiothallis, with anthurium-like leaves, the pale green Gomeza planifolia, Brasso-cattleya Mdme. Jules Hye, Odontioda Bradshawiæ, Cypripedium Priam, C. Minos Youngi, C. Caractacus, the miniature Lælia Lundi, and many other interesting and beautiful orchids. Messrs. Charlesworth and Co., Hayward's Heath, put up a very effective group of orchids, containing fine spikes of Odontoglossum armainvilliersense, O. Lambeauianum, O. percultum, Odontioda Cassiope, O. Bradshawiæ, O. Keighleyense, Phalænopsis Schilleriana, P. Stuartiana, Lælia anceps Sanderiana, and good specimens of Oncidioda Cooksoniæ (A.M.), Brasso-cattleya Queen Alexandra, Cattleya Suzanne Hye, the free-flowering Brasso-lælio-cattleya Cooksoni, L.-c. Bella alba, and B.-c.-l. Joan, rich orange-yellow, with golden throat to the lip.

Messrs. Stuart Low and Co., Enfield, exhibited a large plant of Platyclinus glumacea with its chain-like racemes of silvery-white flowers, a very dark Vanda cærulea, Dendrobium Wardianum, odontiodas, and cypripediums. Odontoglossum Lady Roxburgh, with two branching spikes of graceful, white, purple, and red-brown flowers; another plant of the same hybrid, but with lighter flowers; and Cymbidium Golden Queen (F.C.C.), with greenish-yellow flowers, were all shown by Mr. J. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate; the three plants were capitally grown.

Messrs. Hassall and Co., Southgate, had a small exhibit of Lælio-cattleya Callistoglossa, L.-c. Orieus, with yellow flowers, the handsome Cattleya Empress Frederick, Cypripedium Venus Orchidhurst var., etc. Calanthe Bryan (eight spikes) and Dendrobium Wardianum formed a background for Spathoglottis Colmani aurea, Cypripedium aureum virginale, C. aureum Surprise, C. Boltoni, and spikes of Phalænopsis Schilleriana, and R. Stuartiana, in the group of orchids from Messrs. J. Cypher and Sons.

The very handsome Odontoglossum ardentissimum Ebor var. (F.C.C.) was finely shown by Mr. Shill, gardener to Baron Bruno Schroder, The Dell, Egham; the spike carried twenty-two flowers and buds, and the blooms were white, rose tinted, and heavily marked with brilliant chocolate-red. Mr. H. Alexander, grower to Lieut.-Colonel Sir George Holford, Westonbirt, Tetbury, Gloucester brought up Cypripedium Constantine, a very large green, white, and rose-coloured flower; Lælio-cattleya Dorothy with buff-pink sepals and petals, and Cymbidium Gottsianum Dawn and C. G. The Pearl, two lovely white varieties of a C. insigne hybrid.

Messrs. Jas. Veitch and Son's group of orchids included Odontoglossum Lambeauianum, the curious brown-lipped Oncidium fuscatum, the pretty small-flowered crimson Odontioda Devossiana, the rare Oncidium anthrocrene, Cypripedium aureum virginale, C. Actæus Langleyense, C. Thomsonianum, and Cattleya Trianæ Cortauldiana—a fine form. J. Gurney Fowler, Esq., Glebelands, South Woodford, exhibited a fine plant of

Cymbidium Jas. Davis (A.M.), with pink flowers; this carried a 4ft. spike and a dozen or so of large blooms. Mr. W. A. Manda, St. Albans, sent up varieties of Cattleya Trianæ, C. labiata, and C. Percivaliana, grouped with Polypodium Mandaianum.

Mr. C. J. Phillips, Sevenoaks, and M. de Barri Crawshay, Sevenoaks, exhibited odontoglossums, and the former gained an A.M. for O. amandum.

FRUIT AND VEGETABLE COMMITTEE.

Messrs. J. Carter and Co., Raynes Park, exhibited potatoes in good style, presenting very clean tubers of Sir John Llewelyn, Carter's Monarch, Carter's Early Favourite, Long Keeper, King Edward VII., Royalty, Emperor, and other varieties. Messrs. Barr and Sons, Covent Garden, had a group of particularly brilliant forms of the coloured kales.

In continuation of their displays of seasonable vegetables, Messrs. Sutton and Sons, Reading, exhibited a very handsome lot of curled and coloured kales, Prizetaker leeks, Tender and True parsnips, Superb Early White broccoli, Early Snowball turnips, chicory, seakale, artichokes, Batavian endive, and some excellent potatoes. Apples in great variety were staged admirably by Messrs. W. Seabrook and Sons, Chelmsford. Newton Wonder, The Queen, Allington Pippin, Beauty of Wilts, Cox's Orange Pippin, Lord Derby, and Bismarck were notably good varieties and represented by baskets of large brilliant fruits.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Polypodium irioides pendulum grandiceps, from Messrs. H. B. May and Sons, Edmonton; to Cymbidium Lady Colman var. Golden Queen, from Sir Jeremiah Colman, Bart. (gardener, Mr. Collier), Gatton Park, Reigate; to Odontoglossum ardentissimum Ebor variety, from Baron Bruno Schroder (gardener, Mr. Shill), The Dell, Egham.

Award of Merit.—To Odontoglossum Amandum, from Mr. C. J. Phillips, Sevenoaks; to Oncidioda Cooksoniæ, from Messrs. Charlesworth and Co., Hayward's Heath; to Cymbidium Jas. Davis, from J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), Glebelands, South Woodford; to Crocus chrysanthus var. E. A. Bowles, from Messrs. Barr and Sons, Covent Garden.

MEDALS.

Gold.—To Messrs. R. and G. Cuthbert, Southgate, for forced flowering shrubs.

Silver-gilt Flora.—To Messrs. H. B. May and Sons, Edmonton, for filmy ferns, etc.

Silver-gilt Banksian.—To Messrs. James Carter and Sons, Raynes Park, for potatoes.

Silver Flora.—To Mr. H. Burnett, Guernsey, for carnations; to Messrs. Charlesworth and Co., Hayward's Heath, for orchids; to Messrs. W. Cutbush and Son, Highgate, for forced shrubs and carnations; to Messrs. Wm. Paul and Son, Waltham Cross, for camellias; to Mr. L. R. Russell, Richmond, for forced shrubs; to Messrs. Jas. Veitch and Sons, Chelsea, for greenhouse plants.

Silver Knightian.—To Messrs. Sutton and Sons, Reading, for vegetables; to Messrs. W. Seabrook and Sons, Chelmsford, for apples.

Silver Banksian.—To Messrs. Allwood Bros., Hayward's Heath, for carnations; to Messrs. Barr and Sons, Covent Garden, for early flowers; to Messrs. Cheal and Sons, Crawley, for rock garden; to Mr. C. Elliott, Stevenage, for rock plants; to Mr. C. Engelmann, Saffron Walden, for carnations; to Messrs. S. Low and Co., Enfield, one for orchids and one for carnations, etc.; to Mr. J. Macdonald, Harpenden, for grasses; to Messrs. J. Piper and Sons, Barnes, for hardy plants; to Mr. Maurice Prichard, Christchurch, for hardy flowers; to Mr. G. Renthe, Keston, for rhododendron, etc.; to Mr. Jas. Veitch and Sons, for orchids; to Messrs. J. Cypher and Sons, Cheltenham; for orchids; to Messrs. Mansell and Hatcher, Leeds, for orchids; to Mr. W. A. Manda, St. Albans, for orchids.

Bronze Banksian.—To Messrs. Hassall and Co., Southgate, for orchids; to Messrs. G. and A. Clark, Dover, for hardy flowers; to Wargrave Plant Farm, Lim., Liverpool Street, for alpines.

National Chrysanthemum Society.

Under the presidency of Sir Albert K. Rollit, the annual general meeting of the above society was held in Essex Hall, Essex Street, Strand, at 7 p.m. on Monday, February 3.

There was a moderate attendance of members.

After the usual preliminaries, the President moved the adoption of the report and balance-sheet, as printed and circulated. In doing so, he referred to the promising state of affairs in the society, and spoke highly of the splendid trade exhibits at the November show; of the success of the conference, and the consequent literature which the society is now issuing. The society took its part in connection with the great International Horticultural Exhibition, through its many members. In financial matters the society was now in a good position, and this, the President considered, was a good index of progress. Forty new members were added in 1912, and there were good hopes that more than this number would be added during the year 1913. Mr. T. Bevan seconded the motion, and this was adopted without further comment.

REPORT OF THE COMMITTEE FOR THE YEAR 1912.

The Executive Committee have pleasure in submitting to the members their annual report for the year 1912, a year which has been notable for the progress made in every branch of the society's work.

Sir Albert Rollit, D.C.L., LL.D., was unanimously re-elected president at the annual meeting held in February last. The president was unfortunately prevented from atteding the annual dinner in consequence of indisposition, but he has nevertheless continued his many activities in furtherance of the general work and reputation of the society. The president is using his best endeavours towards obtaining new members, and would like to feel that he is being more generally supported in this direction by other members of the society.

The Publications Committee have arranged for a detailed description of the grand autumn show to be published in the "Transactions" of the society, which will be issued in the early spring, and it is therefore unnecessary to dwell in further detail on the matter in this report.

The annual conference was held at Essex Hall, on November 20, when Dr. Russell gave a lecture, illustrated by lime-light views, on "Soil Sterilisation." By arrangement with some of the leading growers Dr. Russell was able to study the effects of partial soil sterilisation on various chrysanthemum plants, and the results were exhibited at the conference, and partly formed the text for a lecture which was certainly one of the most interesting which has been delivered before this society.

Nine meetings of the Floral Committee were held during the year, when 249 new varieties were considered, as compared with 227 during the previous year. The following awards were made, viz.: 48 First Class Certificates, 18 Commendations, and 4 Awards for Colour.

The table given below sets forth the sections to which First Class Certificates have been awarded during the past five years. The absence of the decorative section in 1912 is due to the fact that under the new classification decorative varieties are not treated as a separate section in themselves, but are allocated to their proper places in the Japanese, Incurved, or Single sections.

	1908.	1909.	1910.	1911.	1912.
Japanese	23	8	19	8	27
Japanese Incurved	—	—	—	—	2
Incurved	3	3	2	2	3
Singles	13	7	12	21	16
Decorative	8	8	21	7	—
Total	47	26	54	38	48

CLASSIFICATION.

The report of the Floral Committee in connection with the new classification was published in the 1911 "Transactions," but it does not appear to have attracted as much attention as was anticipated. Members are requested to make themselves fully acquainted with the new classification, which will assist materially in preventing the confusion which was arising under the old system.

At a special meeting of the Floral Committee held on December 16 the question of granting special market certificates was considered, and after a full discussion it was decided to issue special certificates to varieties which were particularly suitable for market purposes.

At the same meeting it was decided to charge in future a registration fee of 1s. for every variety entered for consideration by the Floral Committee. The Floral Committee are anxious that every good novelty should come under their notice, but they feel it necessary to take some steps to prevent the staging of varieties which are unworthy of consideration and which only serve to waste time.

At the Royal International Horticultural Exhibition held in May last there were only two entries in the class for chrysanthemums, and the society's special gold medal was awarded to Messrs. W. Wells and Co., Lim., of Merstham.

It will be remembered that in the last annual report attention was drawn to the fact that certain types of chrysanthemums did not appear to be receiving the attention they deserved. As a result of this clause in the last report increased attention was paid to these varieties, and the displays which appeared at the 1912 shows were amongst the best that have been seen in the past few years. Attention is again drawn to the fact that special prizes are being offered this year for seedling plants of pompon, anemone pompon, and anemone chrysanthemums.

Your committee desire to express once more their sincere gratitude to the donors of special prizes. During the year a further sum of £25 was placed to the reserve fund which now amounts to £75. The position must be considered very satisfactory having regard to the fact that the society has carried out a very full programme during the past year, in addition to publishing a special volume of "Transactions."

The elections then followed, and Sir Albert Rollit was heartily re-elected as president on the motion of Messrs. Bevan and C. Harman Payne. Mr. John Green was re-elected treasurer; Mr. Thomas Bevan as chairman; Mr. E. F. Hawes, as vice-chairman; Mr. C. Harman Payne, as foreign corresponding secretary; and Mr. Richard A. Witty as general secretary. Mr. C. Harman Payne said that he had now been corresponding secretary for twenty-six years. Mons. Georges Truffaut was very heartily elected as honorary foreign member.

Without the bother of a ballot Messrs. H. A. Farmer, W. Howe, F. W. Ladds, J. B. Linford, J. W. Moorman, J. Rogers, J. I. Simpson, E. F. Such, W. Wells, jun., J. H. Witty, R. W. Leach, and H. Hyatt were elected members of committee.

A very hearty vote of thanks to the president brought the pleasant proceedings to a close within half an hour.

Horticultural Club.

At the annual meeting of this club, held at the Hotel Windsor on Tuesday afternoon, February 4, and presided over by Sir Frank Crisp, Bart., a most encouraging report was presented of the year's work. This showed that the lectures had been well attended, and that membership had doubled during the past two years, and now stood at 192. The financial position of the club is excellent, and a balance of about £170 is carried forward. Reference was made to the generosity of Sir Frank Crisp in providing a cup for the International Horticultural Exhibition; and Sir Harry and Lady Veitch were thanked for their kindness on the occasion of the annual outing.

Thanks were accorded the officers of the society, and these, with the committee were re-elected, and special thanks were given to Mr. R. Hooper Pearson for his services as hon. secretary

At half-past six the annual dinner was held at the Hotel Windsor, and the large dining hall was requisitioned for the occasion owing to the record attendance. Sir Frank Crisp presided, and there were about 110 members and ladies present, including Sir Harry and Lady Veitch, Sir Daniel Morris, and Sir Pieter and Lady Bam.

The programme was a long one, and the musical part of it was arranged and provided by the President. There were the usual loyal toasts and "The Horticultural Club" was proposed by Mr. W. A. Bilney, who reviewed the work of the club, spoke of the honours the King had conferred upon Sir Frank Crisp and Sir Harry J. Veitch, and said that the club had secured a larger room in the Hotel Windsor, and that a billiard table had been provided by the generosity of the President. Ladies had attended the meetings and dinners during the year, and he wondered whether ladies might not be admitted to membership. The President acknowledged this toast, and made kindly reference to the work of Sir Harry Veitch, the treasurer; and Mr. R. Hooper Pearson, the hon. secetary.

The Club took advantage of this occasion to invite the Rev. W. Wilks as its guest; Mr. Wilks will next week have completed twenty-five years of service as secretary of the Royal Horticultural Society. Sir Harry J. Veitch proposed "The Rev. W. Wilks," and in doing so spoke of his long connection with him, of the great services Mr. Wilks had rendered to horticulture, of his zeal and organising ability, and of the phenomenal advances of the R.H.S. from 1,100 members in 1888 to 13,000 members in 1913. The Club wished to show its appreciation of Mr. Wilks' services, and did so by asking him to be present as the guest of the evening. The Rev. W. Wilks was very heartily received, and said that his many friends on the Horticultural Press had not permitted him to be unaware of the fact that there was a proposal on foot to honour him on the conclusion of 25 years' service as secretary of the R.H.S. He reminded those present of the noble work done in the past on behalf of the society, of the splendid work of the present council, and expressed a hope that those who would succeed them might be imbued with the same spirit of devotion to the cause of horticulture. He claimed but a small part in the phenomenal success of the R.H.S., but he was glad to remember that Sir Trevor Lawrence, as president, and Sir Daniel Morris as treasurer, had stood with him in the Society's dark days. He was induced to accept nomination as secretary at a meeting of the Horticultural Club held at an hotel in Covent Garden in 1887, therefore it was not altogether out of place that he should be present at the Club meeting twenty-five years later. Only once, said Mr. Wilks, had there been any division in the Council during those twenty-five years, and it was because of its unity and devotion that the Society had progressed so wonderfully.

The Rev. J. H. Pemberton proposed "The Visitors," and to this toast Sir Daniel Morris responded, and was able to add some interesting points to those already given of Sir Harry Veitch and the Rev. W. Wilks. He said that probably Mr. Wilks had an even wider reputation as the raiser of the Shirley poppies, than as secretary of the R.H.S. Mr. Rogers, who is at the head of the new Department of Horticulture of the Board of Agriculture, also responded, and said he was glad to be brought into touch with so many leading horticulturists, and he hoped that twenty-five years hence the head of the Department would be able to look back on as fine a record of good work as that of the R.H.S. Sir Pieter Bam also responded with a breezy imperialistic speech.

Sir Frank Crisp cut out the toast of "The President," moved a vote of thanks to Messrs. J. Veitch and Sons for so beautifully decorating the tables, and humorously thanked Mr. H. B. May (who should have proposed his health) for the kind words he would have said, thus bringing a very pleasant evening to a close soon after ten o'clock.

ROYAL HORTICULTURAL SOCIETY'S REPORT.

The report that will be submitted by the Council of the Royal Horticultural Society to the annual meeting on Tuesday next is somewhat fuller than usual, and contains much that is of interest. The following extracts are especially deserving of attention:

Wisley Rock Garden and Alpine House.

The planting of the rock garden is proceeding as rapidly as possible, having regard to the desirability of the plants used. It is exceedingly easy to cover a rock garden in a few months with what may be called, more or less, "floral weeds," but such plants will, in twelve months, smother their smaller, slower-growing, and more valuable brethren, so that to obtain a well-planted rock garden it is of all things necessary to have patience, and hasten slowly.

During the past year an Alpine Plant House has been erected above the rock garden, chiefly for the purpose of growing those rock plants to perfection which blossom too early to withstand our wet winters and spring frosts. In this house Fellows will be able to see such plants in flower from February onwards.

Nomenclature of Cape Pelargoniums.

The work of naming and collating the many synonyms of the Cape or Scented-leaved Pelargoniums sent to Wisley for that purpose has been carefully pursued, the task having been entrusted to Mr. John Fraser, of Kew. The list will appear as soon as possible in the "Journal," but it will be necessary to continue the work in 1913, and those having collections are requested to send cuttings to Wisley in February, if they have not already done so, that they may be grown for comparison of both plant and name with those already examined, and their true names established.

Douglas' Journal.

In the early part of the year an application was received from the Department of Agriculture of the United States Government, requesting the loan of the journals kept by Robert Douglas of his travels on behalf of the society through North America in 1824 and the following years, together with permission to publish them if the Department thought fit. Whilst greatly desiring to comply with the request of the U.S.A. Government, which has done so much for horticulture all the world over, the Council hesitated to risk the consignment of the manuscript to such a distance, especially as it has always ranked with those rare and valuable books which are never allowed to be taken out of the library. It was therefore thought better that the society should itself publish this valuable and interesting journal. The secretary was accordingly requested to undertake the task of editing it and preparing it for the press. The work is unavoidably a long one as the writing is often very indistinct, and has faded in places, and it has also been found necessary to refer the identification and nomenclature of villages, rivers, etc., to the U.S.A. Department of Agriculture, but it is hoped that it may be ready for press during the coming year.

Money Deposit with Entries of Exhibitors.

On several occasions great inconvenience has been experienced, especially at the great May and July shows, owing to exhibitors applying for and obtaining an allotment of space, and at the last moment failing to utilise it, thus causing not only unsightly gaps in the staging, but making exhibitors, who have not obtained all the space they desired, think that they have been unduly and unnecessarily curtailed. In order to check this asking for space which they cannot properly fill, all exhibitors at the two great shows at Chelsea and Holland House will in future have to deposit £1 with their application for each space, which deposit will be returned in full if the space allotted is filled to the satisfaction of the Council, but will be forfeited absolutely if the space is not filled, or if in the opinion of the Council the space is not adequately filled.

Primula Conference.

A Primula Conference has been arranged for April 16, 1913, when Sir John Llewelyn, Bart., will occupy the chair. The papers to be read are as follows:

"Himalayan Primulas," by Mr. Craib, of Kew.

"Europæan Hybrids in Nature," by Mr. Reginal Farrer.

"Primulas from a Garden Point of View," by Miss Jekyll.

"Chinese Species of Primula," by Professor Bayley Balfour, F.R.S.

"Europæan Primulas," by Dr. John McWatt.

Diploma in Horticulture.

The committee appointed to consider the desirability of establishing a Diploma in Horticulture have held several meetings during the year, and have consulted a large body of persons whose opinion was considered of value, and have reported that it is desirable to establish such a diploma.

The Council, therefore, at once approached the President of the Board of Agriculture and Horticulture, the Rt. Hon. Walter Runciman, M.P., who most kindly met the committee, and, after hearing their views, promised, after due time for consideration, to communicate with the Council on the subject. The promised communication was promptly sent—it empowers the society to establish an examination, conducted by a joint committee of members appointed by the Board and the society, to determine the recipients of the diploma, which will bear the words "National Diploma in Horticulture, awarded by the Royal Horticultural Society, under a Scheme approved by the Board of Agriculture." The society has consented to bear the expense (over and above the amount received for fees) attaching to this long-needed proof of ability in the art of gardening.

It is hoped that a Degree in Horticulture may also be established by the University of London, and it will in that case be the aim of the Council to make the society's diploma work up towards the University degree.

Parliamentary Committee.

A feeling has been steadily growing amongst horticulturists that their interests require more careful watching with regard to Parliamentary and departmental action than is possible for the Council, which is so fully occupied with the society's more immediate business. It has therefore been decided to establish a Parliamentary Committee whose work it shall be to advise the Council of the society of opportunities—

1. For using the great influence of the society, either in initiating legislation in favour of horticulture, or for influencing measures in any way affecting horticulture, which may at any time be introduced into Parliament; and

2. For informing the Department of Agriculture and Horticulture of the views, and wishes, and wants of horticulturists; and

3. For co-operating with the Department in any useful and desirable movements.

Spraying

The question to-day is not "**Shall we Spray,**" as every gardener knows he **must** Spray, but "What machine or syringe shall I spray with?" All the world answers, Use **only** the **reliable** tested

"FOUR OAKS"

which have won **30** Gold & Silver Medals, many in open competition with other makes. The machine illustrated is the Four Oaks Gold Medal Knapsack Sprayer, **45/-**. OBITUARY.

MR. ALFRED TATE.

The announcement of the death of Mr. Alfred Tate, which occurred under tragic circumstances at his residence, Downside, on the 29th ult., will be received with deep regret by all who had the pleasure of his acquaintance, and particularly by the National Rose Society, of which he had long been a vice-president. In the early part of January last Mr. Tate underwent an operation for cancer in his throat. This was quite successful, and he appeared to be making good progress towards complete recovery, although at times he was much depressed. Mr. Tate had shown remarkable fortitude throughout his illness, but it would appear that the depression had reached a very acute stage on the morning of the date above-mentioned when he committed suicide. Much sympathy is being felt throughout the district of which Leatherhead is the centre with Mrs. Tate and the other members of the family in their bereavement, and in this sympathy our readers will, with ourselves, share.

THE LATE MR. ALFRED TATE.

The second son of the late Sir Henry Tate, whose contributions to the art treasures of London are well known, Mr. Tate entered upon the possession of the Downside estate about twenty-three years ago, at which time the gardens enjoyed considerable fame for their orchids. On taking up his residence, Mr. Tate evinced his strong affection for roses by entering on their cultivation on an extensive scale, and within a comparatively short period became widely known as one of the most enthusiastic and successful amateur rosarians. The rose garden at Downside has an area of about four acres, and may be regarded as a veritable triumph of art over nature. It is certainly the finest garden of its kind in the United Kingdom, and has probably no superior in any part of the world. Possessing a genial temperament and generous in permitting others interested in roses to freely participate in the enjoyment of his wonderfully beautiful garden, he was held in the highest estimation, and by none more so than those with whom he had been so long associated in the management of the affairs of the National Rose Society. Mr. Tate was a regular exhibitor at the exhibitions of the last-named society and those of other of the leading rose societies, and invariably occupied a high positon on the prize list, more especially with garden roses. His collections of these were remarkable alike for the high quality of the blooms and the taste evinced in staging. Mr. Tate was hardly less appreciative of the charms of hardy herbaceous plants, beautiful trees and shrubs, carnations, and water lilies than of roses, and the collections which he formed during his residence at Downside are great and attractive features of the beautiful gardens.

Mr. Tate was a generous supporter of the varions movements in Leatherhead that had for their object the welfare of the inhabitants of the town, and was highly esteemed by his neighbours.

BEST STOUT FRUIT NETS.—Do not be misled by so-called cheaper nets. Do not pay until you have seen and approved of nets. Send your order only. Netting, good strong, and small mesh. Will not rot. As supplied by me to the Royal Gardens. 25yds. by 1 yd., 1s.; by 2yds., 2s.; by 3yds., 3s. Any length or width supplied. Orders over 5s. carriage paid. List of testimonials and samples free. Only address, H. J. GASSON, The Net Works, Rye. Established 126 years.

JOHN K. KING'S SEEDS

STAND
FOR PURITY
AND
SOMETHING MORE.

FOR PURITY.
Because they are home grown, perfectly matured, of proved and tested germination, and selected with the skill and knowledge of experts.

FOR SATISFACTION. See the following:—From Mr. J. Wilson, The Gardens, Alma Lodge, Terrington, St. Clement: "During the past three years I have won 150 prizes for vegetables and flowers, most of which have been from the produce of your seeds."

From Geo. Cater, Esq., Goodrich: "I send you another order for your renowned vegetable seeds, as I am confident from experience that their equal cannot be obtained from any other seed firm in the universe—i.e., germination, quality, and productiveness. Since I was fortunate enough to deal with your respected firm, which I contend is invincible, I have not a single failure on record. I therefore with confidence enclose postal order for a further supply."

TO-DAY IS THE DAY OF OPPORTUNITY.
Therefore send at once for our Manual of Gardening for 1913, the best Seed Book of the season, beautifully illustrated, full of valuable information, and should be consulted by all who have gardens.

ANSWERS TO CORRESPONDENTS.

CYANIDING FOR MEALY BUG.—D. M., Yorks: I should be greatly obliged if you will inform me whether the fumes of the cyanide of potassium will kill growing plants. I have a vinery which is badly infested with mealy bug, and growing up the walls are heliotropes, ferns, scented pelargoniums, etc., which cannot be removed. If there is any fear of these being killed by cyanide, I should be glad to learn of another method of destroying mealy bug.—If the plants are dormant, i.e., if the house is a quite cool one, and the foliage of the wall plants is dry, cyaniding should do no harm if properly carried out. Apart from cyaniding, the business of cleaning such a house and freeing it from mealy bug is a serious one. A safe insecticide should be used on the vines, after the removal of loose bark. The plants on the wall should be severely pruned and thoroughly cleansed by syringing and sponging with a nicotine preparation. After pruning, and before using the insecticide, thoroughly scrub the house with hot water and soap, treating roof, sides, glass, and staging alike. Then tackle the vines and tie them up; next dealing with the plants on the wall, releasing all of them from their supports. Remove the surface soil from the borders, hot lime-wash all wall surfaces, tie the plants into position, and top-dress the borders with sweet, new soil. There must be no half measures about the cleaning process, and with so many evergreen plants on the wall the entire removal of mealy bug will be no easy matter.

GREEN SWEET PEA.—M. S., Purley: Is there such a thing as a green sweet pea, and if there is will you please tell me its name? —There is no sweet pea with green flowers; we remember one that was white with a wedge of green colour on the standard, but it could not be fixed.

MUSCAT VINES.—V., Birmingham: I am planting a vinery with fine canes of Muscat of Alexandria, but, as this variety does not produce pollen very freely, I am wondering whether it would not be better to include a vine of some variety that bears pollen freely; there is really room for six vines. What would be a good variety? Do you think if I obtained extra strong canes in pots, and planted them out now I should be able to let them carry one bunch each this year, without injury? The vinery has an indoor border, 3ft. deep.—There is no difficulty in obtaining a good set of berries on bunches of Muscat of Alexandria, if the conditions are right at flowering time; tapping the rods during the flowering period, in the morning, or dusting the flower bunches with a rabbit's tail, will distribute the pollen. There is really no need for one vine of another variety. Cannon Hall is a shy setting variety, but Muscat of Alexandria is commonly grown by itself in a house. Plant the vines at once, plant firmly, removing the old soil first, and spreading out the roots in the border, in layers, as horizontally as possible. Cut back the rods to a point where, when growth commences, the foliage will at once come under the influence of abundant light. If there is a front wall, cut back to about two eyes above the level of the wall plate. To lay the foundation of a fruitful, long-lived vine, you must forego fruit for the present year.

NAMES OF PLANTS.

E. R., Walkley.—1, Calceolaria Burbidgei; 2, Jasminum nudiflorum.

H. S. P., Coventry.—1, Viburnum Tinus; 2, a buddleia, probably B. variabilis.

Name Missing. — 1, Odontoglossum grande; 2, Vreisia Duvaliana; 3, please send when in flower.

B. C. J., Repton.—1, Mahonia aquifolia; 2, Cupressus macrocarpa lutea; 3, Retinospora obtusa aurea; 4, Pinus excelsa.

W. E. C., Guildford. — 1, Cypripedium Leeanum; 2, Ada aurantiaca; 3, Cœlogyne cristata; 4, Dendrobium Wardianum.

GARDENING ENGAGEMENTS.

Mr. H. Buckenham, who has had abundant practice at home and abroad, under the late Mr. Nesfield and Mr. W. B. Thomas, has been engaged as landscape expert by Messrs. John Waterer and Sons, Lim., Bagshot, Surrey.

Mr. Draper, of Knowsley Hall Gardens, has been appointed to the charge of Lady Smyth's garden at Bower Ashton, Bristol, in succession to Mr. H. Noble, who is retiring after twenty years' service, owing to ill-health.

Mr. R. T. Law, of the alpine department at Lowther Castle gardens, has been appointed gardener to Miss A. Smith, Rhine Hill, Stratford-on-Avon.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Gardening Charities.

In reporting with some degree of fulness the proceedings at the annual meetings, which have been held within the past few weeks, of the two great charitable institutions that are specially associated with horticulture. we have been able to place our readers in possession of the facts essential to their forming a proper estimate of what is being done by the gardening community and those interested therewith in the cause of charity. These facts should be of interest to the gardener, the nurseryman, and the amateur whose means enable him to indulge to the full his taste for gardening, for it is only by a study of them that it is possible to determine whether all that can reasonably be expected is being done in the cause of the aged gardeners and their widows, and of the orphans of those who fall out of the ranks at a comparatively early age. It is certainly desirable that an endeavour should be made from time to time to obtain clear views upon this important point, for unless this is done there may be a tendency on one side to give way to apathy, and on the other to express, without due consideration, an opinion that the members of this or that section of horticulturists have failed to so fully recognise their responsibilities in this matter as could be desired. The study of the facts that are to be found in the record of the proceedings at the annual meetings will be useful also, because of the information gained with regard to the varied ways in which considerable sums may be obtained without very strenuous endeavour or a heavy tax being placed upon the resources of the individual. As we read in the annual report of the Gardeners' Royal Benevolent Institution that during the 74 years which have elapsed since its foundation the large sum of £142,000 has been disbursed in pensions to gardeners no longer able to pursue their avocations, and the widows of gardeners, we are filled with admiration of the generosity evinced by all classes of horticulturists during this long period. While appreciating to the full what has been accomplished in the past, we are highly gratified, as, must be all who are concerned with the welfare of those engaged in horticultural pursuits, by the proofs that at no period in its history has this institution received more substantial assistance than it is receiving at the present time. During the past year the sum of £4,413 was expended in pensions, £225 15s. in gratuities to candidates waiting for election who had been subscribers, and £212 18s. 4d. in gratuities to those awaiting election who had not been subscribers, making a total of £4,852 8s. 10d. Notwithstanding the generous support the institution is receiving at the present time, the income falls considerably short of the necessities of the case, as proved by the fact that after placing 25 candidates on the funds, 42 remained to bear the disappointment inseparable from having to wait another year at least betore they can obtain the assistance they so greatly need. The report of the annual meeting of the Royal Gardeners' Orphan Fund, which appears in another part of this issue, is not less interesting than that of the older charity, because of the evidence it affords of the excellent work that is being done in the cause of the fatherless. By an interesting coincidence, both charities placed 25 candidates on their funds, but fortunately the list of the Royal Gardeners' Orphan Fund was exhausted, and all concerned rendered happy thereby. During the past year the sum of £1,796 10s. was disbursed in allowances to children, making with the amounts previously paid to the little pensioners and candidates a total of £26,542. There is no occasion to dwell upon the great assistance these allowances have been to the mothers or other guardians of the children, for that will be readily understood. But it is a matter of considerable importance to constantly keep in the view the fact that both charities are remarkable for economy of management, presenting in this respect a striking contrast to the charities that undertake responsibilities for the accommodation of their pensioners, whether young or old, in buildings under their own control. Taking into consideration the fact that it has been possible for the two charities to distribute in pensions and allowances £6,648 in the past year, there is no justification for indulging other than in a strong sense of gratitude for the generosity of those who are actively interested in horticulture. It is truly a large sum, but so long as it remains insufficient to enable the charities, or either one of them, to meet the demands that are made upon their resources, an endeavour should be made to augment the annual amount. The best means of support are annual subscriptions, because of their comparative freedom from fluctuations; and in the case of gardeners and many of those engaged in commercial horticulture, there is a distinct advantage in their subscribing to the Gardeners' Royal Benevolent Institution, inasmuch as, should they need its aid, they will have a number of votes, proportionate to their subscriptions, placed at their disposal. It is not every gardener or departmental foreman in a commercial establishment who can afford an annual subscription, and therefore it is essential that it should be generally known that there are other ways by which the gardening charities can be assisted. The aid that horticultural societies and gardeners' mutual improvement societies are able to render is as yet but imperfectly understood, otherwise they would contribute more liberally to the funds of the charities than has yet been the case. Horticultural societies might help by providing a flower stall at their exhibitions, and the other societies might have a collecting box on the table at their meetings, and in many

MR. W. G. BRAZIER,
The new Secretary of the Shropshire Horticultural Society.

districts arrange concerts. Many societies by adopting one of these methods are able to contribute to the funds of one or other of the charities from £5 to £10 annually without a tax being imposed upon any of their members. The opening of gardens once a year at a small charge for admission, might also be more freely exploited as a means of augmenting the funds of the charities. It is not sufficient to open the gardens and provide collecting-boxes, because of the economical habits evinced by many of the visitors on such occasions. Neither should the plate be allowed to take the place of a stated charge for admission to concerts, for the financial results are seldom satisfactory. We refer thus briefly to the two gardening charities for the purpose of calling attention to the splendid work they have accomplished, and showing how all who are concerned with horticulture may participate in the pleasure of strengthening them.

Mr. W. G. Brazier, whose portrait we have much pleasure in presenting to our readers this week, is the recently-appointed secretary of the Shropshire Horticultural Society. He will be known by sight, if not by name, to a very large number of our readers, because he has been on duty in the secretarial tent at the Shrewsbury fêtes for over a score of years. No man could well be better equipped for taking up the arduous duties from which Messrs. Admitt and Naunton lately retired, for Mr. Brazier has been in the employ of these gentlemen for over a quarter of a century. He has a wide and first-hand knowledge of those many details so necessary to the advertisement and management of the Shrewsbury Floral Fête. It is no light task which Mr. Brazier has undertaken, but we feel sure he will maintain "the traditions of the elders," and, if possible, add to the interest, dignity, and extent of the great Salopian function. He will have the cordial good wishes of all who have met him, and of all who have the pleasure of acquaintance with those able gentlemen who founded, and then did so much to make a brilliant success of, the Shrewsbury Show.

The Gordon-Lennox Challenge Cup for Hardy Flowers.—This cup, value 50 guineas, presented to the Royal Horticultural Society by Lady Algernon Gordon-Lennox, is offered by the Council for competition by amateurs at the Holland House Show on July 1, 1913, for a collection of hardy perennial and biennial border plants, including bulbs, tubers, and rhizomes; quite dwarf shrubby plants, such as certain ericas, helianthemums, pentstemons, and dianthus are eligible, but any half-hardy plants which, like dahlias, in most places require starting under glass or with gentle heat, are excluded absolutely. The winner will hold the cup for one year, subject to a sufficient insurance against loss, and a written guarantee to return it in good condition, or, failing this, to refund the sum of £55. On return of the cup in good condition, the Council will present the holder with a small memorial cup of similar design. The object of this competition is to draw attention to the most desirable hardy border flowers (exclusive of annuals, roses, and flowering shrubs), though certain very dwarf-growing shrubby plants, like the old clove carnation, for example, may be included in the term "hardy border plants" for the object of this competition. The same exhibitor may only win the cup once in three years, but should the winner of the previous year be again considered first, the Council will bestow a special award. The decision of the Council is final, and the cup may be altogether withheld at their discretion. The Council will not award this high distinction unless satisfied and assured that the exhibit is, in the main, due to the work and capability of the exhibitor or his employees; on this point the Council may consult any expert not eligible to win the cup, and may reserve decision till the third day.

Proposed Winter Garden for Edinburgh.—At the recent meeting of the Edinburgh Town Council, the question of erecting a winter garden was, on the initiative of Councillor M'Michael, discussed, and its further consideration was remitted to a sub-committee. At the same meeting the sum of £25 was contributed to the prizes that will be offered by the Scottish Horticultural Association at its annual exhibition in November next.

The Chelsea Show.—Plans have been issued by the Royal Horticultural Society of the grounds of the Royal Hospital, Chelsea, and the great tent, showing the provisional arrangements for the exhibition to be held in May next, and these should prove useful to exhibitors in the selection of positions. From the general plan it is seen that the area devoted to the exhibition occupies the whole of the grounds between the avenue of lime trees and the central walk in which the obelisk has a place. The great tent, in which the whole of the exhibits requiring shelter will be arranged, has four spans, and should afford ample space both for the accommodation of the plants and the visitors. The stages for orchids flank the central avenue, and on the eastern side the exhibits will be arranged in irregular groups, while on the western side there will be six rows of tables. Space will be provided for rock gardens, groups of hardy trees and shrubs, and sundries in the open air.

Suffragist Attack on the Orchids at Kew.—An outrage of a peculiarly vicious and wanton character occurred at Kew in the early hours of Saturday, February 8. At five a.m. the stoker found over thirty panes of glass had been smashed in two of the orchid houses, pots broken, and many orchids pulled out of their pots and thrown to the floor. Pots, plants flowers, and glass were in a confused heap. It is reported that a piece of paper carrying the inscription "Votes for women" and a small handbag were found in one of the houses, hence there is reason to suspect that the outrage was committed by Suffragists, and probably by women. It would not be a very difficult matter for anyone to hide themselves in Kew Gardens at night at this time of the year, nor would it be a very serious undertaking to enter the gardens by way of the Old Deer Park, but hitherto these beautiful gardens have been peculiarly exempt from trouble at the hands of disaffected persons, or pilferers. An attack on plants is about as cowardly and cruel as one upon domestic animals, or those in captivity. The extent of the damage done to the orchids has not transpired, but, had the night been very cold and frosty, the damage would have been very serious. The orchid collection at Kew is not so valuable commercially as some collections; that is to say, it does not contain numbers of costly hybrids and varieties, such as fanciers delight in, but it is exceptionally rich in species sent home from all parts of the tropics, and many of the plants, though of little worth at an auction sale, and not notable for their great beauty, are practically priceless, because of their rarity and scientific interest. The British public is very loyal to Kew, and, though over a million people may pass through in one year, the damage done is infinitesimal, and usually due to ignorance rather than wilfulness. Had the outrage been committed, say, on the Saturday afternoon, the culprit or culprits, would, we are certain, have received short shrift at the hands of the many visitors. We may add that prompt means were taken to minimise the damage done, and by the time visitors arrived on Saturday, the glass had been repaired, and there was nothing beyond the closing of the houses to indicate that anything untoward had happened.

Trials at Wisley, 1913-14.—These trials will comprise: Fruits—Berry-bearing fruits other than strawberries, raspberries, gooseberries, and currants, and autumn-fruiting strawberries. Flowers—Antirrhinums, aquilegias, pyrethrums, gaillardias, violas, and bearded iris. Vegetable—Peas, early mid-season potatoes, tomatoes (inside and out), and turnips. The trial of violas was last year so successful, particularly in the late spring and early summer, that it has been suggested (and the Council have accepted the suggestion) that the trial should be continued in 1913 with a special view to the date of the flowering of the various varieties.

Chrysanthemums at Cardiff.—Mr. W. W. Pettigrew, the parks superintendent, reported to the Cardiff Parks Committee at their recent meeting that during the first few seasons of the chrysanthemum display in Roath Park an average of 10,000 to 12,000 visitors attended to witness it, but last year only about 5,000 people attended. He suggested, therefore, that the expense and trouble of cultivating large blooms were not justified, and that the cultivation be confined to decorative varieties, which could be grown at about half the cost. This suggestion was adopted by the committee.

The "United" and the Insurance Act.—The advantages the United Horticultural Benefit and Provident Society is able to give its members, as compared with those obtainable from societies that are open to all classes of the community, are so great that every gardener in the United Kingdom should be a member. Unfortunately, this is not possible owing to age-limit and other causes, but it is possible for all young gardeners to join, and those who neglect their opportunities incur a serious responsibility. The rates of sick pay have, from the first, been on a liberal scale, and, under the new arrangements consequent on the society becoming an "approved" society under the Insurance Act, they are still more so. In several respects, the "United" differs materially from the ordinary friendly societies, but the most important is unquestionably the annual allocation of the surplus to the accounts of the individual members. As gardeners on the whole enjoy better health than do the majority of those engaged in other industrial pursuits, the demand upon the sick fund is less, and the annual allocations form a considerable sum in the course of several years, as proved by the payments that are made to members, or their relatives, from time to time. We have on several occasions called attention to this feature, and we are induced to again remind those who are eligible for election of the fact that, by joining the society, they are able to make some provision for old age, as well as for periods of ill-health. Quite recently two members who were over 60 years of age were able to draw the interest on their deposit accounts, and one member was able to draw his deposit amounting to the substantial sum of £26 14s. 2d. Useful as these sums undoubtedly proved to the several members, they appear

small as compared with the amount of the accumulated profit standing to the credit of a member who had reached three-score years and ten, and had presumably been long a member. In this case the sum was £161 7s. 7d., and the member has drawn upon it to the extent of £61 7s. 7d. Had he been a member of a general friendly society for the same period he would not have had a deposit account, even to the extent of a penny. A mere statement of these facts should be sufficient to show that the approved society which all who are engaged in gardening should join, is the United Horticultural Benefit and Provident Society. The secretary is Mr. A. C. Hill, 35, Alexandra Road, West Kensington Park, S.W.

Manchester Royal Botanical and Horticultural Society.—In their report for the past year the Council of this society state that the anxiety with regard to the future of the gardens at Old Trafford, which was felt in the early part of 1912, has disappeared. They have been able to secure tenants for the gardens until March, 1915, at an annual rent of £2,000, and there is a possibility of a longer lease being entered on before or after that date. They record with much pleasure the fact that the indebtedness of the society is gradually disappearing, the total being now £3,757 17s. 5d., the mortgage having been reduced during the year by £2,000. The Council announce their intention of holding three exhibitions during 1913, the seasons in which they will be held being spring, summer, and autumn. To ensure a full measure of success in carrying out these exhibitions, the co-operation of ladies and gentlemen resident in and around Manchester is invited as subscribers and exhibitors. It is pointed out that the society has no income from annual subscriptions, and stated that an effort will be made to obtain the support of the flower-loving public so that the shows may be self-supporting, and that the work of the society may be extended for the benefit of the people resident in the district of which Manchester is the centre.

Autumn Flower Show at Dumfries.—Owing to financial and other reasons the Dumfries and Galloway Horticultural Society has ceased operations, and it has been proposed to form a new society for the purpose of holding an autumn show in Dumfries. At a meeting held on February 1 the proposal was heartily supported, and the holding of a show was unanimously agreed to. A provisional committee was then appointed, and there is every prospect of the society being firmly established.

Meeting of the British Association. — The arrangements for the meeting of the British Association at Birmingham are making satisfactory progress, and more than two-thirds of the sum of £6,000 required for carrying them out in a manner worthy of the city has been already promised. The meeting will commence on Wednesday, September 10, when the usual business meeting will be held, and will be followed by a presidential address by Sir William White, K.C.B. On Thursday, September 11, the sectional meetings will commence. There will be excursions on the Saturday to Coventry, Kenilworth, Shrewsbury, Stratford, and Warwick, and, in addition to these, special excursions will be arranged for archæologists, botanists, geologists, and geographers. The new features will include a series of citizens' lectures, which will be given each evening during the period over which the meeting extends, except that of the opening day and the Sunday.

SOME CHOICE CLEMATIS.

Few hardy plants of scandent habit are more effective in the garden during their season of flowering than the large-flowered clematis, which are so numerous as to afford a wide range for selection. Provided they can be maintained in a robust state of health, they quickly clothe pillars and arches, and rapidly extend over considerable areas of trellis and wall, and produce their attractively-coloured flowers in such profusion as to produce a delightful display. Unfortunately, it is not always possible to maintain them in so healthy a state as one could wish, owing to the insidious attacks of eelworms, which are so destructive in their effects on those forms of vegetable life that are vulnerable to their attacks.

Probably much might be done to improve matters by avoiding the use of animal manures in their cultivation, and enriching the soil with some of the many excellent artificial fertilisers that are available. By preparing the stations with sweet, fibrous loam, and giving a liberal dressing of lime to the soil, much will be done in the direction of obviating the risk of serious injury from eelworm attacks. As in the case of the Traveller's Joy, and other indigenous species which may in various parts of the country be seen luxuriating on chalk banks, the garden hybrids are lime-loving plants. Therefore liberal proportions of lime, chalk, or lime rubble should be incorporated with the soil previous to planting, and a moderate top-dressing be applied annually, preferably late in winter or early in spring.

This is a suitable time for planting clematis, and the following varieties will form an excellent selection: Admiration, rich salmon-pink; Alba magna, a fine pure white variety; Beauty of Worcester, a medium-sized and finely-formed flower of a blue-violet hue; Duchess of Edinburgh, a charming, fragrant, double white variety; Elsa Späth, purple violet; Fairy Queen, flesh colour, with a pink band down the middle of each petal; Henryi, pure white, one of the finest of the white clematis; Jackmani superba, rich violet-purple; Lord Neville, rich blue; Lucie Lemoine, double white, very fine; Madame Baron Veillard, pale lilac, suffused with rose; Madame Jules Corevon, deep red; Mrs. G. Jackman, white with cream-coloured band in each petal; President, a beautiful claret colour; Queen Alexandra, delicate lavender; and Ville de Lyon, bright red crimson

CLEMATIS MRS. G. JACKMAN.

A good specimen of this beautiful white variety on the terrace wall in the Nuneham Park Gardens.

RECENT ADVANCES IN HORTICULTURE.

Mr. David King, the newly-elected president of the Scottish Horticultural Association, devoted his inaugural address to a consideration of some of the more important advances that have been made in horticulture within recent years.

In his opening remarks, he expressed the opinion that it might with truth be said that recent advances in horticulture in this country had been more along scientific lines than in practical horticulture. The excellence of practical horticulture in Great Britain has always stood very high, and it is difficult to say whether, in the purely practical aspect, we are much further advanced than we were half a century ago. Certainly there has been a great improvement in most of the appliances, and in recent years scientists have let a flood of light in upon many of what were obscure phenomena to the practical man. We have had new races of plants produced, and we have had varieties of fruits and vegetables raised which give heavier yields; but when all is said, considering the materials, and the appliances, which gardeners had to work with then, it is doubtful if there has been so great an advance in the practice as appears on the surface. On the contrary, the old gardeners, without technical education of any kind, except what they could gather by reading and intercommunication with their fellows, could produce crops, making allowance for the differences in the kinds of fruits and vegetables grown then, which would compare favourably with those grown to-day.

Soil Knowledge.

In no department of scientific horticulture, perhaps, has so great an advance been made as in our knowledge of the soil and the use of manures. It is only within comparatively recent years that we have come to realise that the soil is not the dead, inert substance we formerly supposed it to be, and this has completely revolutionised many of our ideas both as regards the working and the manuring of it. We now know that the soil teems with life, and we know that life can exist only in the upper layers of the soil. We know, too, that some of these minute organisms are beneficial, and that certain of them are injurious, and this knowledge of their properties and their mode of life has given us the key to failures in the past where it seemed that success should have been certain. This knowledge enables us to see where we were wrong when, in our practice of trenching ground, we killed the organisms by putting the soil they inhabited in the bottom of the trench, away from the influence of the air, and bringing the sterile soil in the lowest depths to the surface, there to remain until it had had time to be brought into a state fit for their habitation, and thereby we wasted time. That is one instance out of many where science has come to the aid of the practical man, and has demonstrated to him that he was wrong. It has also come to his aid in connection with the application of manures to the soil, and now the farmer and the gardener know well why, when potatoes are heavily dosed with farmyard manure alone, stems and leaves only are produced at the expense of tubers; and why heavy dressings of lime, by killing out the soil bacteria, do more harm than good, and can only be beneficial, as in the case of the trenching referred to, after the soil has again become fit for habitation by these organisms.

One of the most recent, and, from some points of view, probably the most interesting of experiments in connection with soil, especially soil used in the cultivation of plants under glass, is "soil sterilisation." We are familiar with the old process of "baking soil," and, of course, this kind of sterilisation is not new. But scientific sterilisation is a very different matter. Here the object is not to kill all life in the soil, but only to kill off those organisms which are injurious to plant life, so that the beneficial ones may have free scope to multiply and render the soil fertile, again. It seems that the beneficial organisms cannot live, or, at any rate, cannot perform their functions, in an acid soil, and that all such soils require to be neutralised before they can be made fit for healthy plant growth.

Mendelism.

Perhaps the most important of recent discoveries in scientific horticulture is that of Mendel's Law of Inheritance. While it does not upset the old notion that "like begets like," it has completely revolutionised our ideas about the breeding of both plants and animals, and it enables us to understand phenomena which previously were unintelligible to us. Now we know why the old, haphazard method of fixing varieties of plants produced by crossing was so tedious and troublesome. Now we know that numbers of cross-bred plants which were discarded as useless before the discovery of this law were discarded simply because the breeders did not understand the outward evidences of its existence. It required a Mendel to interpret these things, and possibly not one in a hundred of the scientists of his time would have been able to do so. In fact, even the celebrated botanist, Carl Naegeli, did not seem to understand Mendel's results after they were obtained. That wonderful law tells us that, when we cross two plants in order to blend or mix two desirable characters, though what we desire may be entirely absent in the first family, nevertheless the factors are there, and most assuredly will appear in the next family. No factor, though it may disappear for the nonce, is ever lost, and breeders of both plants and animals, provided their stocks are pure, may now make their crosses and be quite certain of the results. And not only this, for with a knowledge of this law they are saved all the trouble and loss of time involved in the old haphazard methods of fixing, which are now superseded by a method at once scientific and simple. Even on the human race itself, it is impossible to say what the influence of this wonderful law may be, and possibly it may yet be shown that much of the present-day social legislation is framed on wrong lines altogether. In fact, the science of Genetics is one of the most important subjects with which biologists have to deal at the present time.

Decorative and Rock Gardening.

As regards decorative gardening, there has been quite a revolution in recent years. The advent of so many fine decorative roses, the great improvement in such flowers as the antirrhinum, the sweet pea, and many other hardy subjects, and, more than anything else, perhaps, the greatly increased favour which hardy plants generally now enjoy with a large and increasing number of people, have brought about a great change in this kind of gardening. There is a growing tendency to a less formal style, although the formal garden is by no means a thing of the past. Bulbs for spring bedding and naturalising in wild gardens are being more and more used, and beautiful-flowered trees and shrubs have now a place in decorative gardening which they never had before. In fact, the whole tendency is in the direction of hardy subjects of various kinds, and the whole style of the garden is undergoing a corresponding change. Nor is it to be wondered at that this interest in hardy plants has taken such a hold on people, for the saving in glass-house accommodation is very considerable, to say nothing of the fuel and labour that are saved. And there is another advantage in the use of herbaceous and other hardy subjects in that they give a succession of bloom from early spring to late autumn, whereas tender subjects like geraniums and other summer-bedding things only last a few months.

Rock or alpine gardening, too, is becoming more popular, and the fine displays of these gardens at the great International Horticultural Exhibition held in London in May last showed that the experts are not neglecting this branch of the subject. Then there is wild or semi-wild gardening, which gives great scope for the introduction of novel features, and which is also becoming very popular with some people. In fact, the chief charm of these hardy subjects—trees, shrubs, and herbaceous plants—lies in the fact that they can be used in such a variety of ways, and they give so little trouble.

New Plants.

The last decade or so has witnessed the introduction from North China of a large number of new plants, many of which will no doubt be valuable accessions to the stock of hardy plants for the decoration of gardens; but as most of the regions of the globe have now been explored, we cannot hope for such a supply of new plants in the future as we have enjoyed in the past, and, for decorative subjects, at any rate, by and bye we shall have to rely almost entirely on the hybridists to supply our wants. This, however, we need have no fear about, for what they have done in the past for the rose, the rhododendron, and azalea, the carnation, orchids, and many other things, they will do for other subjects which are likely to be of use in horticulture in the future.

Improved Races and Varieties.

Leaving out hardy annuals like the sweet pea and some others among the non-shrubby decorative subjects, none, perhaps, has made such a great advance in popular favour in recent years as the perpetual-flowering carnation. The evolution of this flower has been phenomenal, and the varieties nowadays are very fine indeed, and its qualities as a cut flower have given it such a lead over the border carnation that the altter will probably have to take a lower position in the future. Another plant in which great improvement had been effected in recent years is the tuberous-rooted begonia, but it is doubtful if, as a bedding plant, it will supplant the pelargonium, unless, perhaps, in mild, moist localities, which suit its requirements best.

In the case of old favourites like the rose, sweet pea, chysanthemum, dahlia, gladiolus, etc., the hybridists have also been busy, and many new varieties of these are constantly making their appearance; in fact, there is no finality anywhere, and almost every year there is some new break or some new race appearing. But like tastes in gardening, there have been great changes here, too, and the great aim now seems to be to produce decorative varieties in preference to varieties which are chiefly, if not only, useful on the exhibition table. In the case of the chrysanthemum, the growing of big blooms for exhibition purposes seems to have reached its limit, and a reaction in favour of the decorative varieties, including the singles, seems inevitable. It is the same with the dahlia. How often now do we see the old show dahlia at our flower shows? Its place has been taken by the cactus, collarette, and other useful kinds—decorative kinds—and it is the same with many other genera. And this change in taste in gardening is not to be regretted, for the simplicity and ease with which many of these hardy plants can be grown will do more, perhaps, than anything else to make decorative gardening more popular amongst the masses of the people; and if ever the Garden City idea takes root in this country, as no doubt it will in time, this wealth of decorative plants will be one of its greatest assets.

(To be continued.)

Honour to Messrs. Adnitt and Naunton. — In recognition of their twenty-eight years of excellent service as joint honorary secretaries of the Shrewsbury Show, the Council of the Royal Horticultural Society have appointed Mr. H. W. Adnitt and Mr. W. W. Naunton honorary life Fellows of the society.

NEW PLANTS AND FLOWERS.

CROCUS CHRYSANTHUS E. A. BOWLES.

A very beautiful crocus, raised by Mr. Van Tubergen, and named after Mr. E. A. Bowles, who is one of the leading authorities on crocuses. The flowers are rich yellow, of fine form and substance, and on the outer surface the lower half of each segment is beautifully marked with rich reddish brown. A fine, free, vigorous crocus. A.M., R.H.S., February 4. Messrs. Barr and Sons, Covent Garden.

ODONTOGLOSSUM ARDENTISSIMUM EBOR.

A splendid form with large, shapely flowers. The white ground-colour is tinted with rose, and heavily and regularly blotched and spotted with bright chocolate-red. The specimen exhibited carried twenty-two flowers and buds on a superb spike. F.C.C., R.H.S., February 4. Baron Bruno Schröder (gardener, Mr. Shill), The Dell, Egham.

POLYPODIUM IRIOIDES PENDULUM GRANDICEPS.

A variety imported from Queensland. The fronds are freely divided at the apex, and consequently depend somewhat, but in a large plant this pendulous habit becomes strongly marked, the fronds hanging down like those of Platycerium biforme, and a yard or so long. It promises to be an easily-grown warm house fern, capable of making a large specimen. F.C.C., R.H.S., February 4. Messrs. H. B. May and Sons, Edmonton.

CYMBIDIUM LADY COLMAN, VAR. GOLDEN QUEEN.

A very effective form of the hybrid between C. eburneo-Lowianum and C. Tracyanum. It has large flowers of a bright greenish yellow, with faint lines or rosy dots. The lip is yellow, white, and brown. F.C.C., R.H.S., February 4. Sir Jeremiah Colman, Bart. (gardener, Mr. J. Collier), Gatton Park, Reigate.

ONCIDIODA COOKSONÆ.

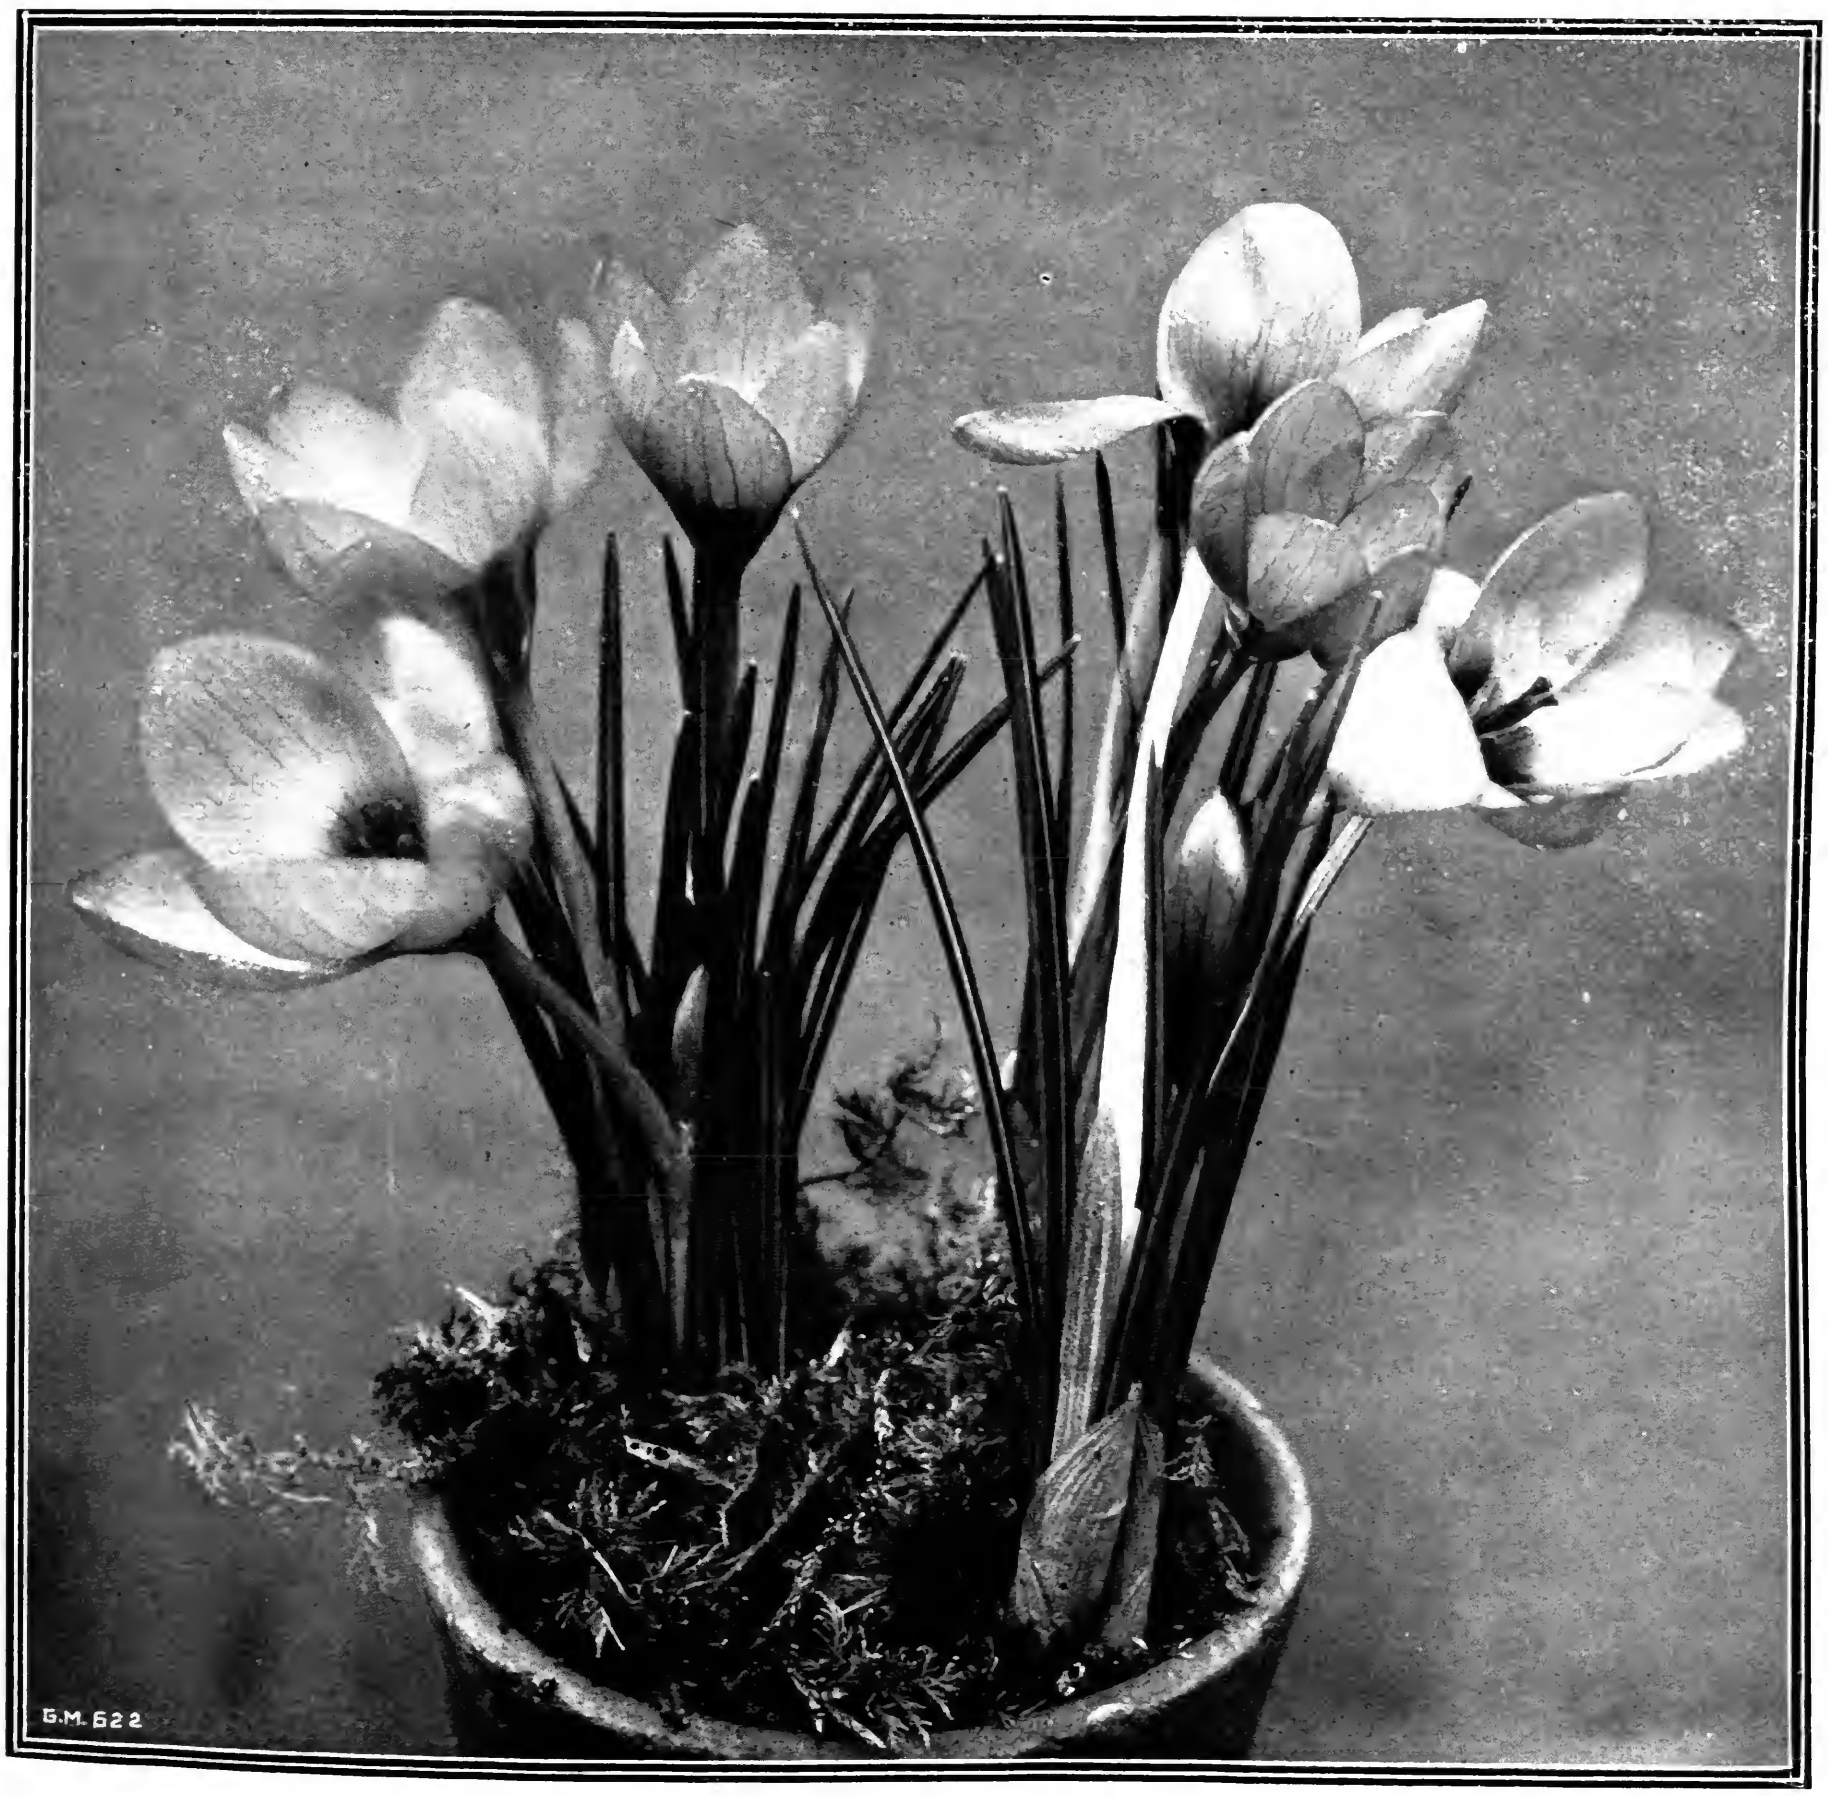
A very striking and novel hybrid between Cochlioda Noezliana and the well-known Oncidium macranthum. In growth and length of spike the influence of the last-named orchid is very much in evidence, but the cochlioda has modified the flowers and given them a rich red colouring, though there are yellow tips to the petals. A.M., R.H.S., February 4. Messrs. Charlesworth and Co., Haywards Heath.

CYMBIDIUM J. DAVIS.

This has an erect spike, rising nearly five feet high, and bearing numerous flowers of fair size at its apex. It is the result of crossing C. Schröderiana with C. insigne, the influence of the latter being very much in evidence. The flowers are buff-pink with reddish brown lines, and the white lip has red-brown markings. A.M., R.H.S., February 4. J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), Glebelands, South Woodford.

ODONTOGLOSSUM AMANDUM.

A shapely hybrid with white flowers that are marked with a few rich red-purple blotches and spots. The parents are O. Pescatorei and O. Wilckeanum. A.M., R.H.S., February 4. C. J. Phillips, Esq. (gardener, Mr. Bucknell), The Glebe, Sevenoaks.



CROCUS CHRYSANTHUS E. A. BOWLES.

A beautiful golden-flowered crocus, with broad segments that are finely coloured at the base, on the outside, with bright brown. A.M., R.H.S., February 4, Messrs. Barr and Sons, Covent Garden.

THE CONSERVATORY IN FEBRUARY.

During most of the month of January the gap caused by the passing of the chrysanthemums causes many gardeners no little anxiety. It has been especially so this year when the very late-flowering chrysanthemums have not altogether fulfilled expectations. It is interesting, but disappointing, to speculate on the reasons which caused the latest varieties to be merely late in their blooming, instead of very late, in a season when many of the earlier varieties matured later than usual. The remedy seems to be to grow the latest batch in rather more varieties in the hope that another season there will be sufficient plants in flower during the first half of January at the least.

But with the beginning of February the number of shrubs and plants which may be forced into bloom greatly increases each week, and will lessen the decorator's anxieties. Perhaps the greatest difficulty at this season is to obtain roof plants in bloom. With the pillars of the conservatory there is not so much difficulty; these may be attractively clothed with such plants as the deliciously fragrant Luculia gratissima, which will soon have finished its period of usefulness; and the strong-growing fibrous-rooted begonias, of which B. Luzerna, which bears spotted leaves and large trusses of bright pink flowers, B. Haageana var. Drosti, B. gracilis, and B. fuschioides may be instanced.

One of the best roof plants now obtainable is Tibouchina semi-decandra, which has produced its rich purple-blue flowers for a considerable time, and shows no signs of ceasing. No more striking floral combination than these rich-coloured, velvety blooms overhanging a score or so of plants of Jacobina chrystostephanas can be easily imagined. The yellow-tipped, glowing orange flowers of the Jacobina, strikingly beautiful as they are, gain distinction from the association. Other seasonable roof plants are Abutilon insigne, A. Golden Fleece, A. Boule de Neige, and Lantana salviæfolia (syn. L. delicatissima). To gain the maximum effect the lantana should be loosely trained, so that the pale lilac flowers hang over a group of some white blossom. The Abutilon insigne alone would not arrest the attention of the lover of gorgeous colours, but there is, nevertheless, a deal of beauty in the widely-expanded reddish flowers, which are suitable for acting as a foil to the rich yellows or orange-scarlets of other plants, and the flowers of the abutilon improve on acquaintance.

The great change in the method of arrangement of the plants in the conservatory synchronised with the decay of carpet bedding and ribbon borders in the flower garden. The then fashion in the conservatory very nearly approached the style of the ribbon borders, except that the rows of plants were not composed entirely of distinct sorts. While one deprecates the departed style of arranging the plants of each species or variety at regular intervals, as far as circumstances and plants permit, and looks more favourably upon the present-day system of grouping, we must not overlook the fact that, unless employed with skill and taste, this becomes a crude and inartistic arrangement, savouring much of the advertisement poster. A show house, containing batches of plants arranged slavishly in their kinds and often in their colours, with a few evergreen subjects interspersed at intervals, may possibly possess the virtue of originality, but it would owe any attraction it possessed to the meretricious grace of crude colour mass, and would have no more real beauty than the vases of sweet pea blooms one sees at the summer flower shows, which are examples of colour massing pure and simple, the beauty of form being entirely hidden.

A more artistic method of plant arrangement would be to still group the different kinds of plants which are in flower, but, as is the case with many of the forced shrubs—the cytisuses, staphyleas, deutzias, and Buddleia asiatica, for instance—and plants such as the Lindenbergia grandiflora, recently illustrated in the GARDENERS' MAGAZINE, Begonia Gloire de Sceaux, and many epacris, to name only a few now in flower, unless they possess graceful habit or plenty of foliage they should not be grouped alone. An occasional batch of very floriferous Begonia Winter Cheer, or B. Gloire de Lorraine, when suitably placed, have decided colour values, and often would be very artistic, but it is the repetition of these types, triumphs of cultural skill though they be, which appears crude and monotonous. Daintier and more artistic combinations may be obtained by grouping in association two classes of plants, whilh have flowers of distinct colours.

The method advocated has its difficulties, and requires for its successful adoption unfailing taste in the blending of colours and forms of foliage. Otherwise the decorator will steer clear of the rocks of crude colour only to come to grief in the shoals of discords. The use of scarlet flowers with the yellows, for instance, must be sparingly practised, and the various difficult shades of colour are often best either kept separate or associated with white. The most generally successful combinations are yellow or pink, red and pink, lemon-yellow and pale heliotrope, and in a good light yellow and white.

The arrangement of the forced bulbs present certain difficulties when it is wished to break away from the patches of scarlet tulips, of yellow narcissus, or of white lily of the valley. The companion plant must be of comparatively low stature and of moderate delicacy of foliage or the bulbous plants will either be dwarfed or hidden. In these instances, little bushes of the beautiful Acacia Baileyana, with a profusion of golden flowers, or of A. ovata, may be thinly interspersed amongst either the lily of the valley or the scarlet tulips with equal propriety. Polygala myrtifolia grandiflora, which bears carmine-rose coloured, pea-like flowers in graceful quantities, is another useful shrubby plant, which may be associated either with white or yellow. Buddleia officinalis, Jasminum primulinum, and Coronilla glauca are three very free-flowering shrubs, which may be obtained for the February decoration of the conservatory without any difficulty.

The forcing of herbaceous plants in a few kinds has long been practised in order to add variety to the conservatory, and lately certain annual plants have been pressed into service with excellent results, and in this direction we shall probably find many more plants which may be similarly utilised. Of the herbaceous plants, the spiræas, Dielytra spectabilis, and Solomon's seal are the most generally used for flowering at this season, but they might well be supplemented by Doronicum plantagineum excelsum, aquilegia hybrids, and the trolliuses, and other kinds will readily suggest themselves. But it will be found that it is the herbaceous perennials with tuberous and fleshy roots which are the most amenable to this gentle forcing.

CECIL AUBREY.

PEAR PLANTATIONS.

In plantations and alongside walks most of the best pears are grown in the form of bushes and pyramids. It is not everyone who has the conveniences for growing pears as cordons or trained trees on walls, and a few remarks on the general treatment of trees so grown may be of some value and assistance to many of my readers. It will be understood that these remarks or notes apply to the cultivation of pears in those districts where it is possible to grow the trees and ripen the fruits with a reasonable amount of success. In many parts of the kingdom climatic and other unsuitable conditions make it a precarious venture to plant pears in open quarters.

Soils and Situations.

Soil and situation are all-important factors to be considered; heavy, retentive soils are unsuitable to the requirements of the pear, and where it is necessary to plant trees in soil of this character, means must be taken to make it more in accordance with the requirements of the roots. The desirable conditions are a free root run devoid of stagnant moisture, and in dealing with heavy soils it is necessary to drain, trench, and add such materials as will add to the lightening and porosity of the staple. Possibly this may appear unnecessary trouble and expense, but if the best results are desired the initial outlay will well repay itself. Good, sandy loam of a fair depth, overlaying a well-drained subsoil, suits the pear admirably. In a soil of this class, bush trees on the quince stock are the most profitable, both for quality and quantity of the fruits. Should, however, the soil be of a very light and porous nature, trees on the quince will, unless well mulched and watered, become stunted in growth after being planted a few years. In such cases it is advisable to have trees worked on the pear stock. Possibly growth may be too vigorous, but by judicious root-pruning this evil may be corrected, and once the trees become fruitful there will be slight danger of undue vigour in growth occurring.

Regulation of Growth.

The tree I prefer is one that might be termed a bush cordon—that is, a tree with several main branches standing well apart from each other, and treated in the way of pruning as an ordinary cordon. By this method the maximum of light and air is admitted to all parts of the tree, and consequently the fruits are of good size and quality, and, further, the free admission of sun and air thoroughly matures growth and materially assists the formation of fruit spurs. The management, or I might say mismanagement, of pear trees growing in the open is often deplorable.

One often hears the complaint, "My trees grow freely, but I fail to have any fruit." Many such cases have come under my notice, and the trouble is usually due to two causes—faulty pruning and neglect of the roots. Many of these trees are a perfect thicket of growth, light and air is

quite shut out, and under such circumstances it is not to be wondered at that the fruit is conspicuous by its absence. By removing from half to two-thirds of this excessive growth, and if upon examination the roots require restriction, resort to root-pruning to counterbalance the action of the growths cut out, the balance of the tree will be restored, growth will be restricted within reasonable limits, the wood will be well ripened, and blossom buds will be freely formed in due order.

Pruning of the branches and of the roots are important details, and the limits of these notes will not permit an exhaustive explanation, but it occurs to me that if common sense and less rule-of-thumb methods of procedure were introduced into the management of fruit trees, the results would provide far better and higher returns than are so often obtained nowadays.

Varieties of Merit.

The selection of varieties is a very important matter. In the first place, certain varieties will do well in one district, and probably in an adjoining neighbourhood fail to give good crops, and the fruits will be of inferior quality. This is a difficult matter to explain, but the fact remains. Again, there are certain varieties which succeed practically everywhere where the conditions are at all favourable to the growth of pears. In selecting varieties for planting it is advisable to ascertain which varieties are best adapted for the particular district. More or less unknown varieties should be tried before planting them in large numbers. It is most necessary in growing pears to meet an extended demand that a goodly number of varieties should be selected. The uncertainty both as to cropping and premature ripening of the fruits is well known, and unless a certain amount of overlapping occurs, there is a likelihood of a shortage of ripe fruits—probably when most needed.

Some of the old varieties of merit have been pushed to one side by later introductions having fruit of large size and high colour, but in some instances lacking the rich flavour of the smaller fruits of those old favourites. For a display on the dinner table, large, handsome fruits are desirable; but for eating, medium-sized fruits are preferable. The following are well tried and suitable for bush culture, viz.: *Beurre Giffard, *Souv. du Congrès, *Williams' Bon Chretien, *Beurre d'Amanlis, Triomphe de Vienne, *Madame Treyv, *Louise Bonne of Jersey, *Durondeau, Comte de Lamy, *Emile d'Heyst, Marie Louise, *Beurre Hardy, Beurre Diel, *Beurre Superfin, *Doyenne du Comice, Glou Morceau, Winter Nelis, *Josephine de Malines, President Barabe, *Bergamotte d'Esperen, Beurre Easter, Duchess de Bordeaux, and *Oliver de Serres. The varieties marked thus (*) will in themselves provide fruits over an extended season, and are good in every way. As I have previously mentioned, it is possible that in certain districts some of the varieties not "starred" may be equally as good, if not better, than those "starred."

Thinning Flower Buds.

Many trees fail to set their fruits owing to the excessive amount of blossom which is allowed to develop, exhausting the energies of the tree in this direction instead of their being devoted to the embryo fruits. Some form so many flower buds, that unless the greater portion of them are removed, the possibilities of a crop are very remote. I believe that if the practice of more or less thinning down of the flowering buds was more generally recognised, there would be crops of fruit in the place of partial or entire failure as so often happens.

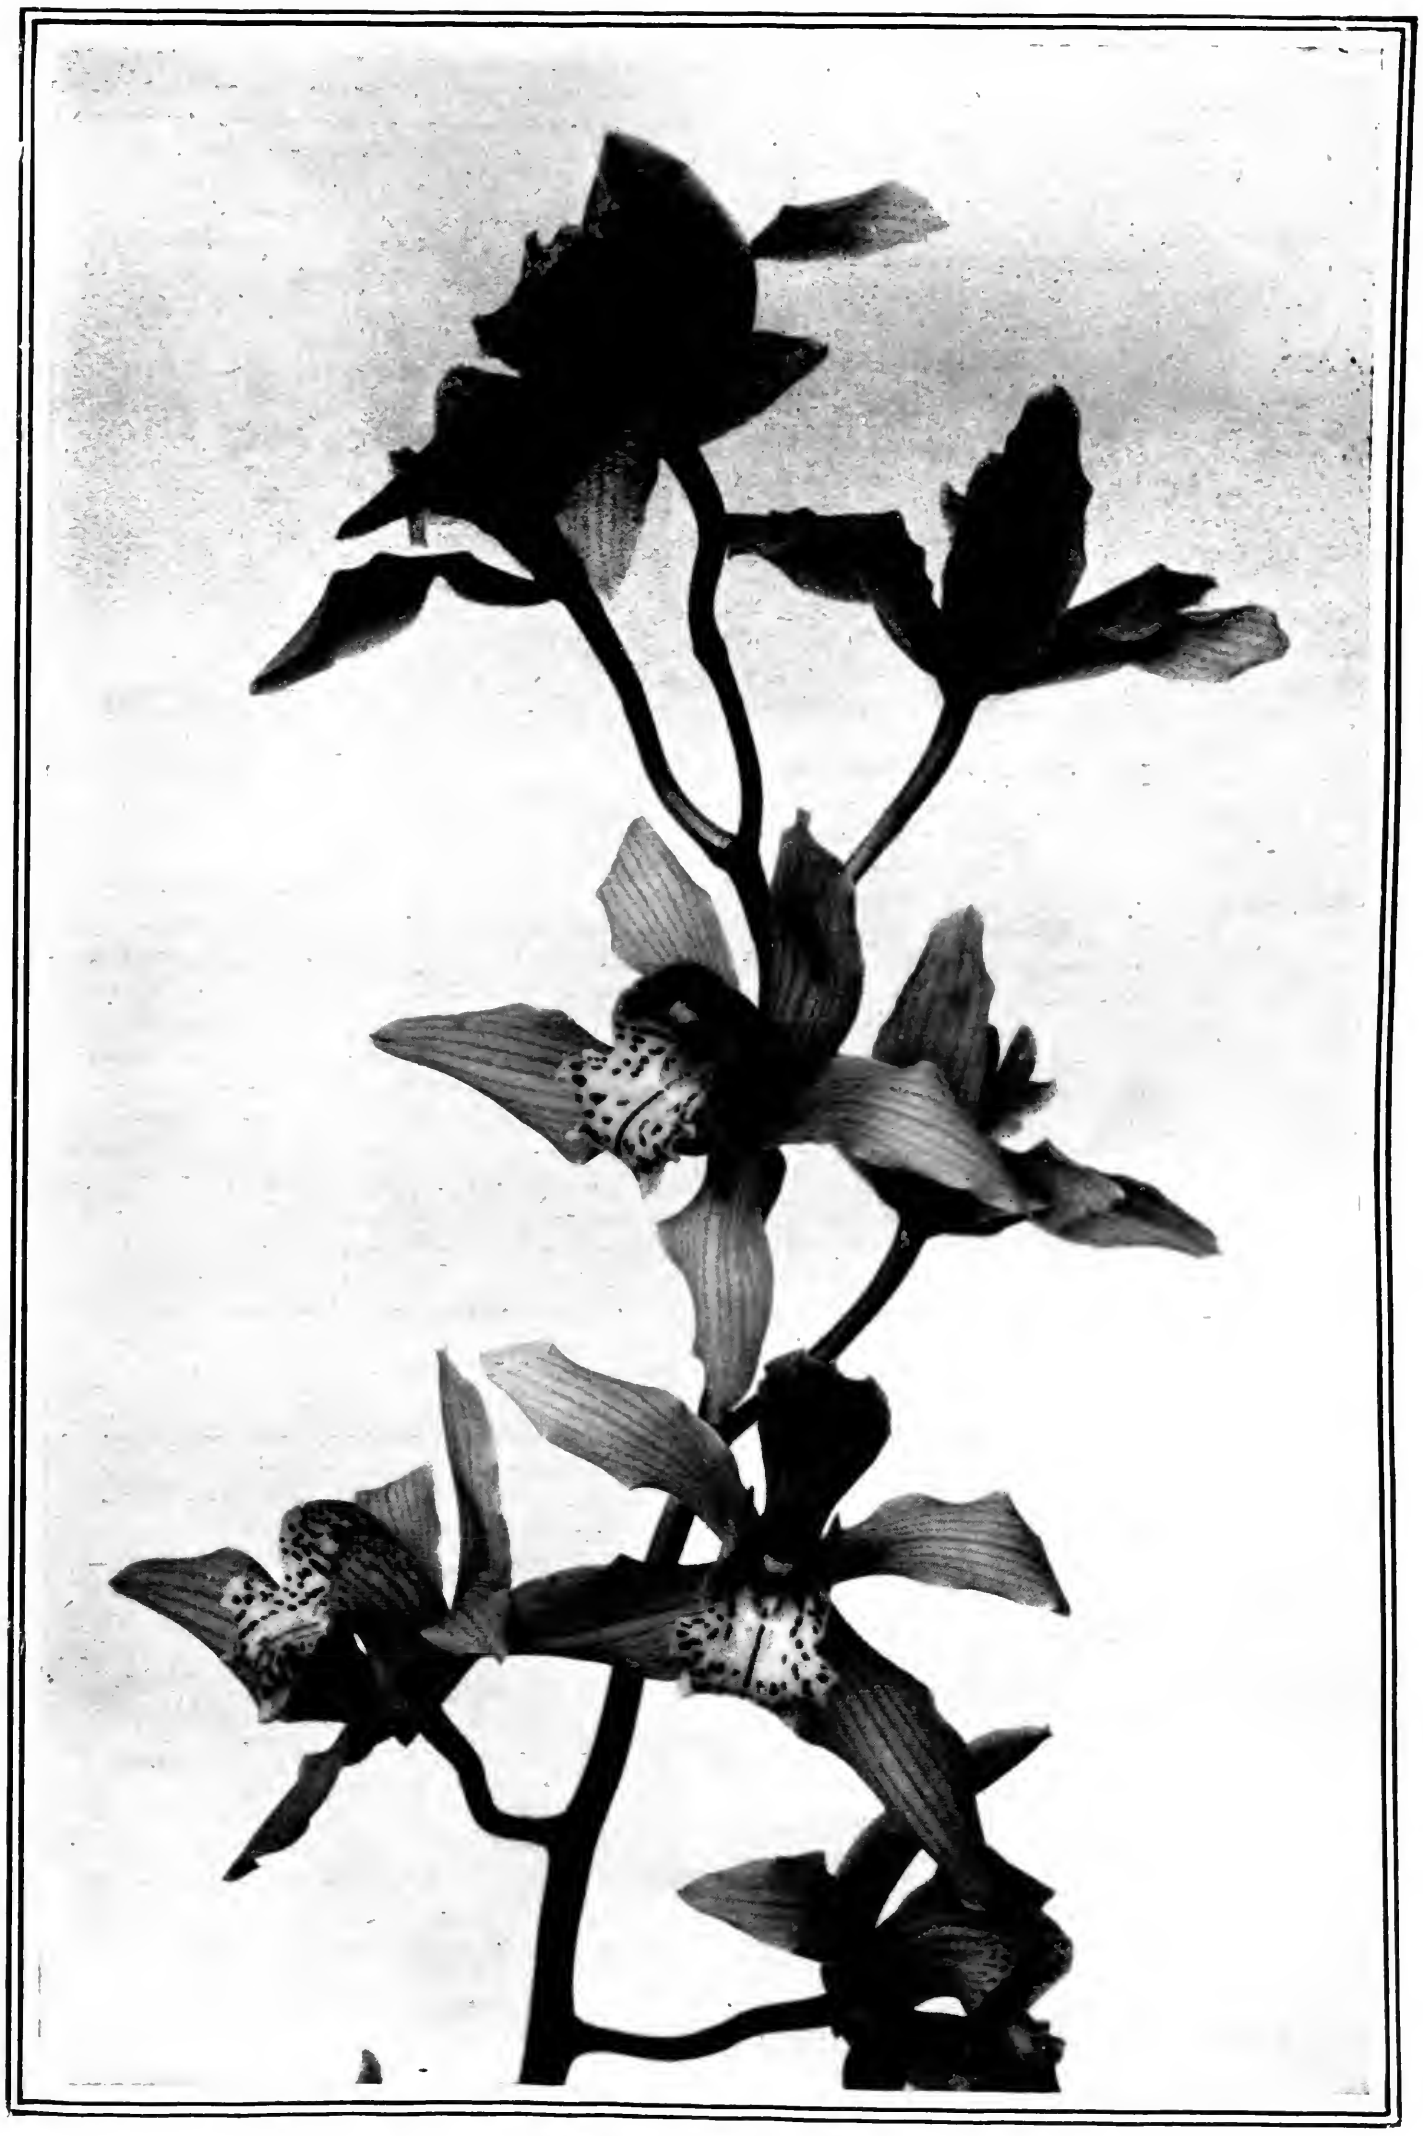
The pear is not so susceptible to diseases and insect pests as some of the hardy fruits, nevertheless it is essential to keep the trees clean and to attack any fungoid or insect pest which may show itself. Healthy trees, like healthy human beings, are seldom troubled with disease, and when trouble in this manner does occur, it may safely be inferred that something is amiss with the general health of the tree, and a searching examination should be made for the source of the trouble. W. MESSENGER.

Woolverstone Park Gardens.

CLERODENDRON FRAGRANS

If someone would take this deliciously-scented species in hand, and induce it to lengthen and broaden its corymb of flowers, so that the plant would boldly advertise itself instead of waiting to be discovered, what a desirable warm greenhouse plant it would be! The white flowers are of good size, and sufficiently numerous, but their unfortunate habit of remaining tightly congested at the apex of the plant, nestling between the large handsome leaves, effectually prevents it from becoming popular. One's ideal of the plant would be that of the habit of Clerodendron fallax. These remarks also apply to the double-flowered variety, in which the blossoms are equally fragrant and are flushed with pink.

CECIL AUBREY.



CYMBIDIUM J. DAVIS.

An elegant hybrid bearing a very tall, erect spike of buff-pink flowers, which are lined with reddish-brown. A.M., R.H.S., February 4. J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), Glebelands, South Woodford.

SPRAYING FRUIT TREES.

In the bulletin on apple orcharding issued by the Ontario Department of Agriculture, full directions are given for the suppression of insect pests, and the prevention of fungoid diseases, as for soil preparation, planting, etc. The cultivation of apples has attained to a high state of development in the province, and it being a point of some practical importance to know something of the procedure of fruit growers in our Colonies we reproduce the short chapter on spraying, which is as follows:

While spraying is not a panacea for all the ills of the fruit grower, it is absolutely necessary to the production of fruit free from blemishes, and to the vigour of the tree for protection against insects and fungous diseases. To be of any value the mixtures applied should be of proper strength, applied at the correct time, and the work thoroughly done. Until quite recently it was believed that trees should just have a misty covering. Too much stress was laid on this claim with the result that the work was not thorough and results were not uniform, and often very discouraging. The trees must be thoroughly sprayed—every part completely covered.

A steady high pressure is indispensable to accomplish good results, not only from an economical point of view, but for efficiency. A pressure of from 100 to 150 pounds should be used, and this is most easily obtained and maintained with a gasoline or some other power machine. Hand pumps of the double acting kind can give a pressure of 100 to 125 pounds, but unless the operator is closely watched this pressure will not be continued for any length of time. A 2½ horse-power gasoline engine with two lines of hose can discharge from 1,000 to 1,500 gallons per day, depending upon the convenience of tanks and water. The amount of spray required per tree varies considerably. Five or six gallons per tree is a fair estimate, although in very large trees the amount will be more. Of course, in a season of a short crop a less amount may be applied for coddling moth; and trees devoid of bloom may be left until the others are done, and then as time permits these may be sprayed to effectually protect the foliage from the attacks of injurious insects and fungi.

The wind is seldom too strong for spraying. In fact, a stiff breeze is preferable in that it carries the spray into the tree. Spray with the wind and do as much of the tree as possible. Spraying three-quarters of the tree with one wind is possible. One side of the tree can be sprayed as it is approached. For large trees it will be found convenient to stop again directly opposite, and then complete the other side at the third stop. Medium-sized trees can be covered by stopping only twice. Spray as much of the tree as possible with one application, for the wind may not be favourable when it is necessary to complete the work by spraying the other side of the tree.

Spray Outfits.

For orchards up to ten acres a double-acting hand pump will answer the purpose. These may be secured with complete outfit, including 150 gallon tank for from 60 to 80 dollars. Good pumps of this kind are very popular with the smaller fruit growers, and have the advantage of being constructed for connection with an engine if desired. Barrel pumps are still quite popular and serve their purpose very well for small home orchards. For orchards of 10 acres and over one or more power machines will be found indispensable. A good gasoline engine will pay for itself in a couple of years by the labour saved and in efficiency of work, besides being of great use for pumping water or sawing wood when not used at spraying time.

Since high pressure is necessary for good results, the quality of the fittings, such as rods, hose, and nozzles, should be of the best. Use nothing but the strongest kind of hose, and have an extra supply on hand, together with plenty of brass hose couplings. Two lines of hose are necessary in almost all cases, one for the man on the ground and another for a man on the tower. Of course, in young orchards, the tower may be dispensed with and the spraying done from the top of the tank. For the tower man a hose 10 to 12 feet long and a rod 8 feet long are best; for the man on the ground 25 to 35 feet of hose and a 10-feet rod.

The most widely-used nozzles are probably of the "Friend" type, particularly for the lime sulphur spray. Brass elbows which set the nozzle at an angle are particularly recommended while spraying for codling moth, where it is necessary to direct the spray downward into the fruit clusters.

Considering these points in successful spraying of large orchards it is apparent that the first essential in a pump is its ability to maintain a pressure of not less than 150 pounds with two lines of hose and four large nozzles. Only pumps that are high grade in every other respect can maintain this pressure.

Spray Mixtures.

Lime sulphur is now the most important and widely-used spray. There are four forms in which it can be had: (a) commercial, (b) home-boiled, (c) home-made concentrated, (d) self-boiled. The commercial form is manufactured by several firms, and sold in barrels containing 40 or more gallons, which should be diluted to a standard ascertained by an hydrometer. This mixture, while it is somewhat more expensive than the home-boiled wash, has found favour with the grower who does not wish to make it himself. The use of home-boiled spray is being extended, specially since the home-made concentrated mixture has been devised. The mixture is easily made and the boiling outfit is inexpensive. A very efficient and simple device is made as follows:

Make a tightly-jointed box of 1½in. boards or 2in. plank, 3ft. wide 6ft. long, and 15 or 18in. deep. The bottom should be made of heavy sheet iron closely nailed and extending about an inch beyond the edges. This is placed upon a cement, stone, or brick foundation, high enough to permit of a good fire being kindled beneath. A chimney of some kind is placed at one end to create a good draught. This cooker will boil a barrel of the mixture very quickly, owing to its large heating surface. It will be necessary to make a cover of boards running lengthwise, with a space between the two centreboards for stirring. Insert a faucet at the most convenient corner, slightly above the bottom, to prevent sediment from escaping.

How to Make the Wash.

The formulæ generally used for the ordinary home-boiled mixture are 15lb. sulphur, 20lb. lime, 40 gallons water, and 18lb. sulphur, 20lb. lime, 40 gallons water. Fill the receptacle about half-full of water. While this is boiling make the sulphur into a paste by gradually adding water and stirring. Measure out the lime, add it to the boiling water, and while slaking vigorously, add the sulphur. If the boiling is so vigorous as to splash over add a little cold water, or in the case of steam plants, turn off the steam. It is particularly necessary that boiling be vigorous, but if the barrel or box be filled too full a great loss of material will occur. It is well to keep the receptacle covered with an old sack or boards. To obtain good results and render the greatest proportion of the sulphur into solution, it is necessary to boil for from 45 to 60 minutes, and stir constantly. As soon as the boiling is done, either hot or cold water should be added to make up to 40 gallons, and the solution strained through a fine wire screen. The mixture is much better applied hot. In case the mixture has unavoidably been allowed to stand until next day, it should be reboiled to dissolve any crystals that have formed.

Concentrated lime sulphur is made by increasing the amount of lime and sulphur in solution. The advantages of the concentrated wash are that large quantities can be made at one time, and that it can be stored for long periods by excluding the air. A small quantity of mineral oil added will float over the surface, thereby rendering it air-tight. The fact that this concentrated wash will keep has induced a great many growers to manufacture it, especially in view of the fact that it can be made early in the spring before the rush of other work is on.

The methods of procedure are similar to the preparation of the ordinary spray. The proportions used are 1 part lime to 2 parts sulphur. The common formula is 50 pounds best lime, 100lb. flour or flowers of sulphur made up to about 40 or 45 gallons. Sometimes the ingredients are used in the proportion of 60 to 112, or 65 to 125. So it is seen that they vary somewhat. A very convenient way is to use one bag of sulphur (112lb.) and 1 bus. of lime (70lb.). This does away with the trouble of weighing and the extra handling necessary.

To about 10 gallons of boiling water add the lime. While this is slaking make the sulphur into a paste, and carefully break up all lumps. If this is neglected a considerable portion of this sulphur will remain in the sediment. While slaking is going on add this sulphur paste, stir constantly, and then add enough boiling water to make up the 40 or 45 gallons when completed. Colour tests are not reliable. From 45 to 60 minutes' boiling will be sufficient.

When good materials are used and cooking carefully done, very little sediment will remain. If any considerable amount of sludge is left it should be washed, and this water used in the preparation of the next batch.

Rules for Diluting before Spraying if a Specific Gravity Hydrometer is Used.

Put the hydrometer in the clear liquid when it is cool and the sediment has settled. Note the reading. Suppose this is 1,240 sp. gr. The proper strength for use before the buds burst is 1030. To determine how much water is required to dilute a wash reading 1240 to get a strength of 1030, divide the first three figures to the right of the 1 by 30, that is 240 divided by 30=8. This means that each gallon of the wash may be diluted with water to make 8 gallons of the strength of 1030.

For use on apples and pears just before the blossoms burst, the proper strength is about 1009. To get this strength from a wash reading 1240, divide in the same way the first three figures to the right of the 1 by 9, that is 240 divided by 9=26⅔. This means that each gallon of such a wash for this application may be diluted with water to 26⅔ or 27 gallons.

For the application just after the blossoms have fallen, and for any sub-equent applications, if any are given, a strength of about 1008 is satisfactory. To get this we proceed in the same way as above, and divide the 240 by 8, which gives us 30, thus indicating that for this application each gallon may be diluted to 30. In brief the rule is: Take the reading of the wash and divide the three figures to the right by 30 for the first application; by 9 for the second, and by 8 for the third; and dilute each gallon with water to the number thus obtained in each case

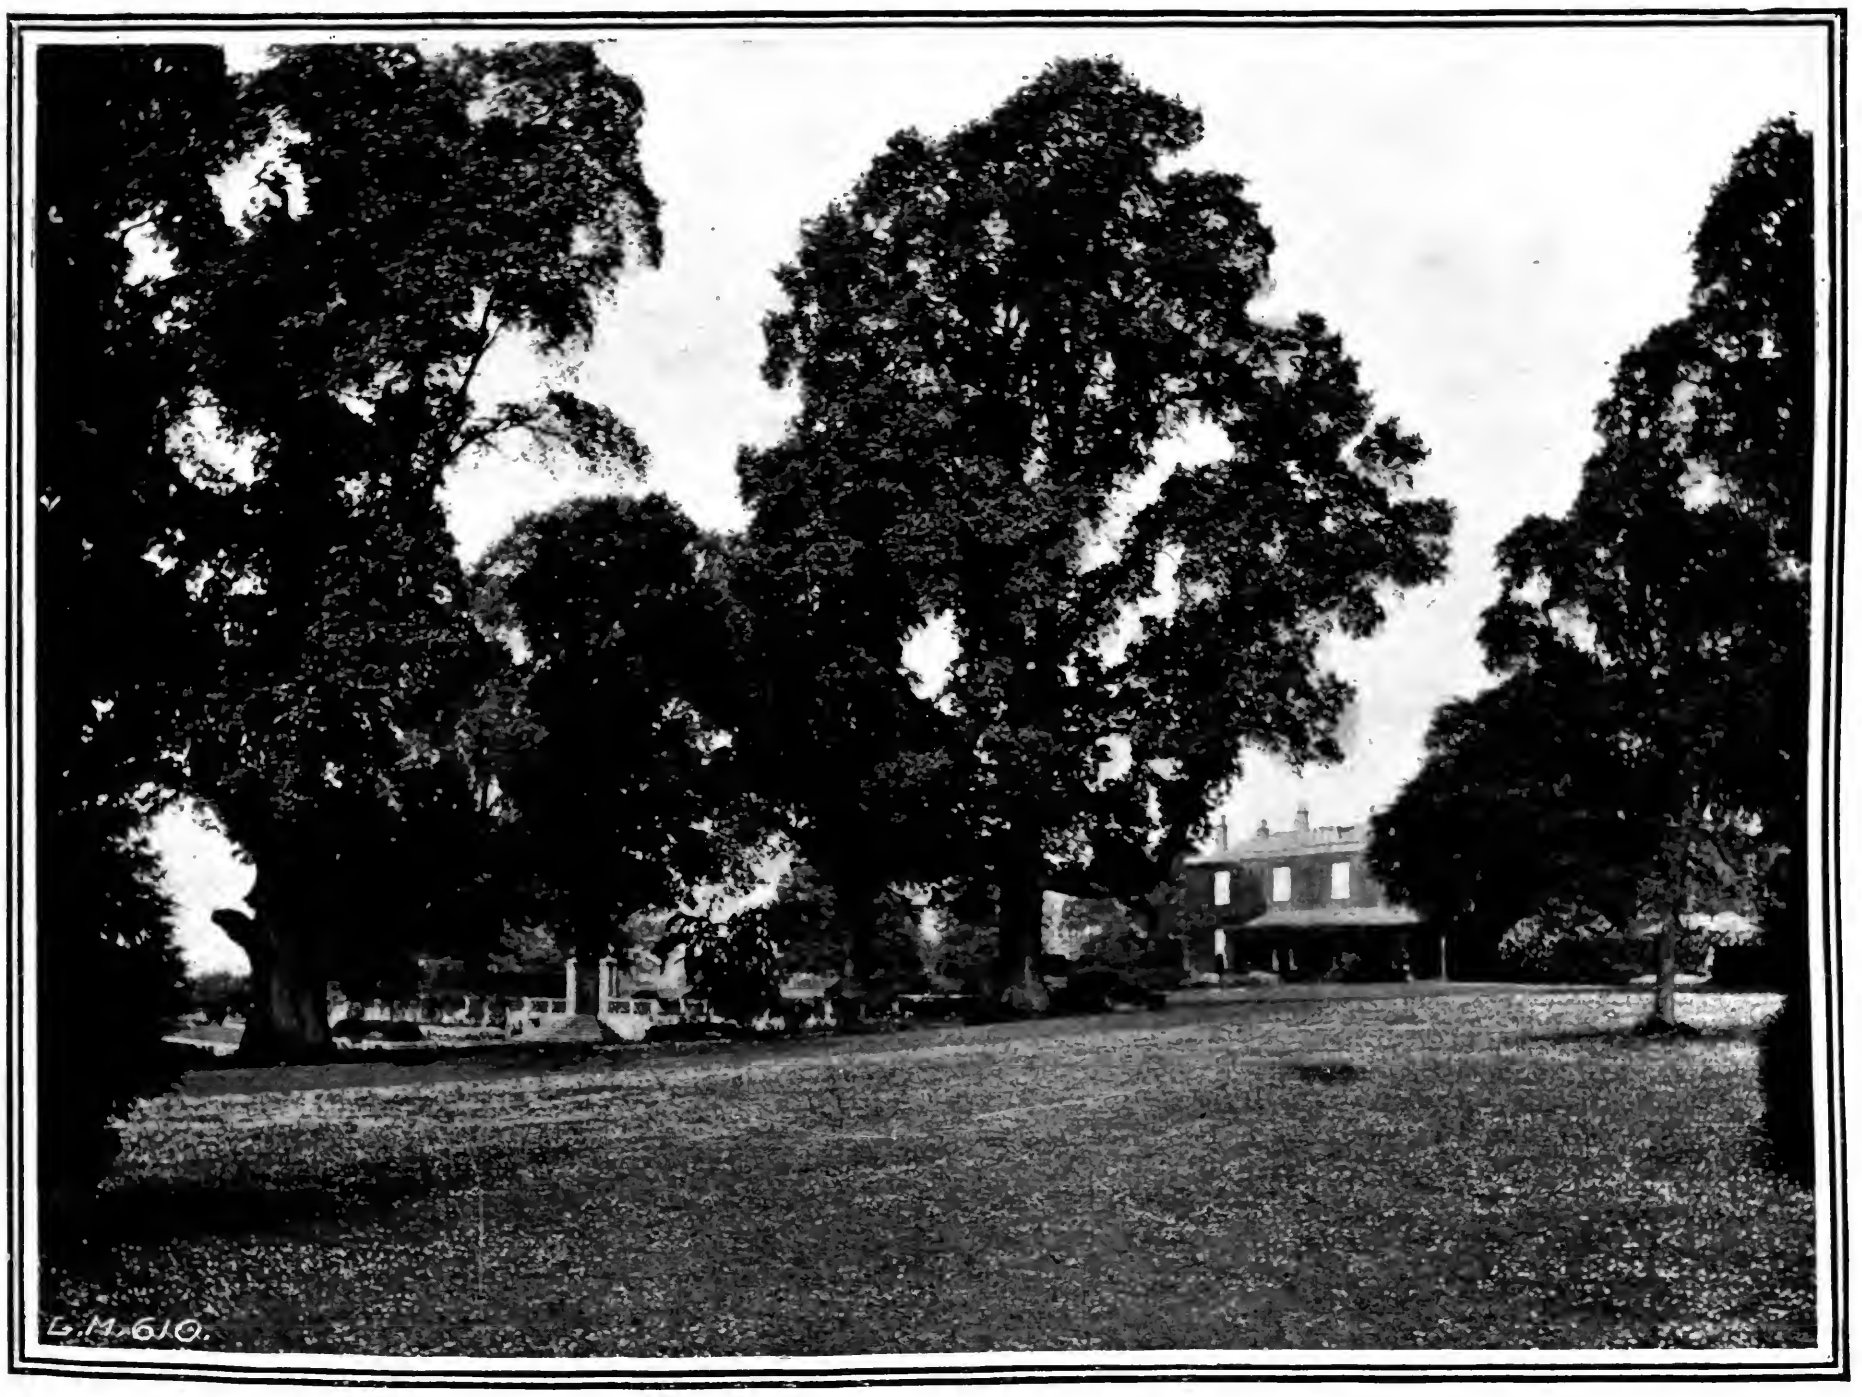
HARTPURY HOUSE.

Throughout the broad county of Gloucester the name of Gordon-Canning is a household word, and, while it is safe to say that the West Country possesses no sportsman more keen than the squire of Hartpury, it is equally true of Mrs. Gordon-Canning that no lady in the district is fonder of her garden. This does not imply that the squire has no interest in the garden, for, on the other hand, he has, but his tastes have a utilitarian bent, as he is keen on fruit, whereas his wife finds her pleasure mostly in flowers, of which Hartpury can boast a varied and choice collection. Old-fashioned garden flowers in general, and perhaps lavender in particular, appeal very strongly to Mrs. Gordon-Canning, but she possesses that faculty which has not been given to many lovers of this class of flowers, i.e., good taste to know just where to put them in a garden where the ancient and the modern, so to speak, are intermingled with each other.

Hartpury.

But where is Hartpury, did I hear someone ask? Just four or five miles distant from the grey old towers of Gloucester Cathedral, and pleasantly situated above the lowlands of the Severn Valley. Hartpury has little to boast of historically, and the red-brick house, which is not architecturally striking, occupies the site of an agricultural habitation, which over a century ago was known as the Three Ashes farm. The outlook from Hartpury House, however, is different to what it used to be, and the only relic of the old farmstead that remains is an antiquated feeding crib for cattle which has been thatched to preserve it, and it stands in the stable yard as a connecting link with other days. The story goes that, in the days before Hartpury House was built, nearly the whole of the village was under the plough, and grew corn, but so much have methods of farming changed that most of the land is grass, and from the mansion one looks out over verdant pastures studded here and there with fine timber trees. In the style of its farming Hartpury has merely changed, but in another particular it has gone back, for the residents of the parish can no longer boast of the orchards, for which at one time it was famous. Like every other parish in the Vale of Severn, Hartpury, of course, has its orchards, but the glory of many of them has departed, and a few old relics of trees here and there that have defied the ravages of time mark different sites "where once an orchard smiled."

Credit belongs to Mr. and Mrs. Gordon-Canning for many improvements that have been made in the gardens at Hartpury, and I hesitate to say whether it is the most attractive in the spring, the summer or the autumn; while even in the winter there is much that is interesting to any lover of ornamental trees and shrubs. Up to within five or six years ago the garden stopped abruptly in front of the house, and was divided by a fence from the pasture land beyond, but the happy idea was conceived of making a garden here in Old English style, and looking at it now one fails to realise that it is really a modern addition, so delightfully does it seem to be blended in with the whole surroundings. It is not everybody, by the way, who conceives the idea of making a new garden in order to provide work for the unemployed, but this was Mr. and Mrs. Gordon-Canning's way of looking at it, and, what is more, many of the men, not being quite of navvy build in point of physique, were regaled with Bovril to stimulate their efforts, and to this day the memory of the Bovril at Hartpury is not forgotten. Mr. H. Prentice, the head gardener, who is always busy, by the way, was particularly active when the new garden was being formed, and probably his staff of unskilled labour gave him some trouble, but it is to his credit to say that from the time the work was completed in October, the lawns were sown down and the planting finished by April.



ANCIENT TREES AT HARTPURY HOUSE.
With glimpse of Mansion and Flower Garden beyond.

Flower and Rose Gardens.

Referring still to this feature, you approach the new garden by a flight of steps from the terrace, and the old-world appearance of the whole is enhanced by the flagged walks and the quaint little plants that grow in the crevices between the stones. Any suspicion of monotony is relieved by beds of dwarf azaleas, andromedas in variety, kalmias, Berberis Wilsonæ,

daphnes, and so forth, and the clumps of golden yew, now becoming well established, are a feature in themselves. The retaining walls of grey stone are a nursery of interest, for there you may see Escallonia montevidensis, which grows well and flowers beautifully, Escallonia Ingrami, Desfontainea spinosa, Jasminum primulinum, Chimonanthus fragrans, Elæagnus japonica aureo-media, Euonymus radicans argenteo-variegata, Rapheolepis ovata, and many other choice plants, along with the old-fashioned rosemary. Growing out of the walls are clumps of Aubrietia Dr. Mules, Cerastiums tomentosum, grandiflorum, arvense, and others, Dianthus fragrans, and numerous plants besides, while the lower part of the wall is furnished with Cotoneaster horizontalis, which in the autumn season is a picture of beauty. There are bulbs in the borders with Iris beds also of Mrs. Gordon-Canning's favourite lavender, as well as groups of the charming China and polyantha varieties.

Yew Gardens.

Another of Hartpury's own features is the yew garden, where you have a charming view of the Malvern Hills, and the sombre evergreen hedges enclose interior beds furnished with Andromedas floribunda, japonica, speciosa, calycina, racemosa, and others, Ghent and Mollis azaleas single and double, pernettyas, kalmias, Ericas arborea, carnea, and mediterranea, Rhododendrons præcox, Cunningham's White, Wilsonianum, and others, with roses and herbaceous plants. A rhododendron bed outside is furnished with the best varieties grown to give a colour effect, and this is flanked with specimen hollies in variety that are kept in form by the use of the visitor does not know about their names and habits Mr. Prentice can tell him. Just to mention a few of the deciduous order. There is a fine collection of acers, including A. tartaricum, lovely in the autumn; A. platanoides, A. striatum, A. dissectum roseo-marginatum, A. atropurpureum, and others. Amelanchier canadensis is lovely in spring and autumn, and Amygdalus communis fruits well at Hartpury. Most of the berberis are represented, as well as Clerodendrons trichotomum and arborescens purpurea. Enonymus europæus grows freely in the gardens and adjoining woods, and charming in their seasons are Exochorda grandiflora, Forsythias suspensa and viridissima, Kolreuterias frutescens and paniculata, the latter being beautiful in the autumn; Magnolia conspicua, a fine specimen; nuttalias, philadelphuses, potentillas, prunuses, Rhus copallina, and

FLOWER GARDEN, HARTPURY HOUSE.
Embellished with beds of Mollis Azaleas, Rhododendrons, Violas, etc.

reticulata, and a fine plant of Carpenteria californica grows under the terrace wall, which in turn is furnished with roses, clematises, Akebia quinata, and Ozothamnus rosmarinifolius, which, through the summer, is covered with its white flowers. There are pillars covered with Dorothy Perkins rose, Clematis Jackmani superba, and American Pillar rose, which is a great favourite, and at the west end of the lower terrace walk you come suddenly upon a quaint little lily pond, in which there is a choice collection of nymphæas.

The rose garden is near to and directly in front of the mansion, and is connected with the terrace by a paved walk, where dainty plants grow out from between the stones and seem to enjoy the privilege of being allowed to do so. The rose garden contains a comprehensive collection of summer and autumn-flowering varieties, and knife in April. Further on, you see a bold clump of Retinospora filifera, and further still several fine oaks, which have held more than one fox in days gone by, and under the shade of which many a tea party has been held in Mr. Gordon-Canning's nursery days. Yellow daffodils nod their heads about here in the spring, a bed of golden hollies takes your attention, and the walk leads you on to a semi-wild garden, where, amongst a host of other things, you see beds of Penzance briars, clumps of Pyrus floribunda, flowering cherries, with some beds of Iris germanica, day lilies, berberis in variety, Lonicera fragrans in full bloom at Christmas and deliciously sweet, and all kinds of other interesting plants.

Choice Shrubs.

I speak correctly when I say that the shrubberies at Hartpury are filled with choice and beautiful things, and what the others, ribes, spiræas, staphyleas, viburnums, etc.

For the lover of evergreen shrubs there is much to interest, including arbutus in variety, Benthamia fragifera, which fruits freely, buddleias, ceanothuses, cotoneasters, daphnes, Euonymus japonica, and E. radicans, argenteo-variegata. There are Garryas elliptica and macrophylla, Genistas præcox, hispanica, and others, with Hypericum calycinum, which is largely used for ground work. Several varieties of myrtus are represented, along with olearias, Osmanthus ilicifolius purpurea, a lovely shrub; Phillyreas Vilmoriniana and latifolia, Pæonias fruticosa, leptospermums, rhamnuses, skimmias, and a number of varieties of veronica, including several of the New Zealand forms, which stand the winter outside. These are but a few, but they give an idea of the

wealth of evergreen shrubs in the Hartpury gardens.

Lavender and Herbaceous Borders.

To reach the kitchen garden from the mansion you pass along a broad walk, passing on the way the wall of the stables, on which you notice some very large fig trees, annually giving good crops of fruit, and are much prized by Mr. and Mrs. Gordon-Canning. A grand old Wistaria sinensis has wandered far on the wall, and a Banksian rose hard by is a pretty sight at the end of May. You notice good plants of Romneya Coulteri as you pass along, and a herbaceous border filled with conspicuous clumps of choice plants. In order to reach the kitchen garden you must cross a drive, and through an iron gate, leaving the Queen Charlotte walk, with its green grass and wide border of lavender on each side, fronted with grey-foliage plants. Here, again, you see evidence of Mrs. Gordon-Canning's passion for lavender, for wherever it can be employed effectually it is planted with other grey-foliaged plants. Alterations here have made the gardens much bigger, and a new feature has been introduced in the shape of posts with festooned chains of roses and beds and borders which, in the seasons of the flowers, are gay with white violas, May-flowering tulips, Emperor William viola, antirrhinums, pentstemons, with double arabis, forget-me-nots, and tulips for spring effect. As you leave this latest addition to a beautiful garden through an iron gate into the vegetable and fruit department, you retain a memory of lavender through seeing a tablet on the wall on which the following lines are inscribed:

"Lavender sweet, your soft grey flowers,
Bring to our memory rest from cares;
Bid us hope that the sunlight hours,
May throw shadows of love in the coming years."

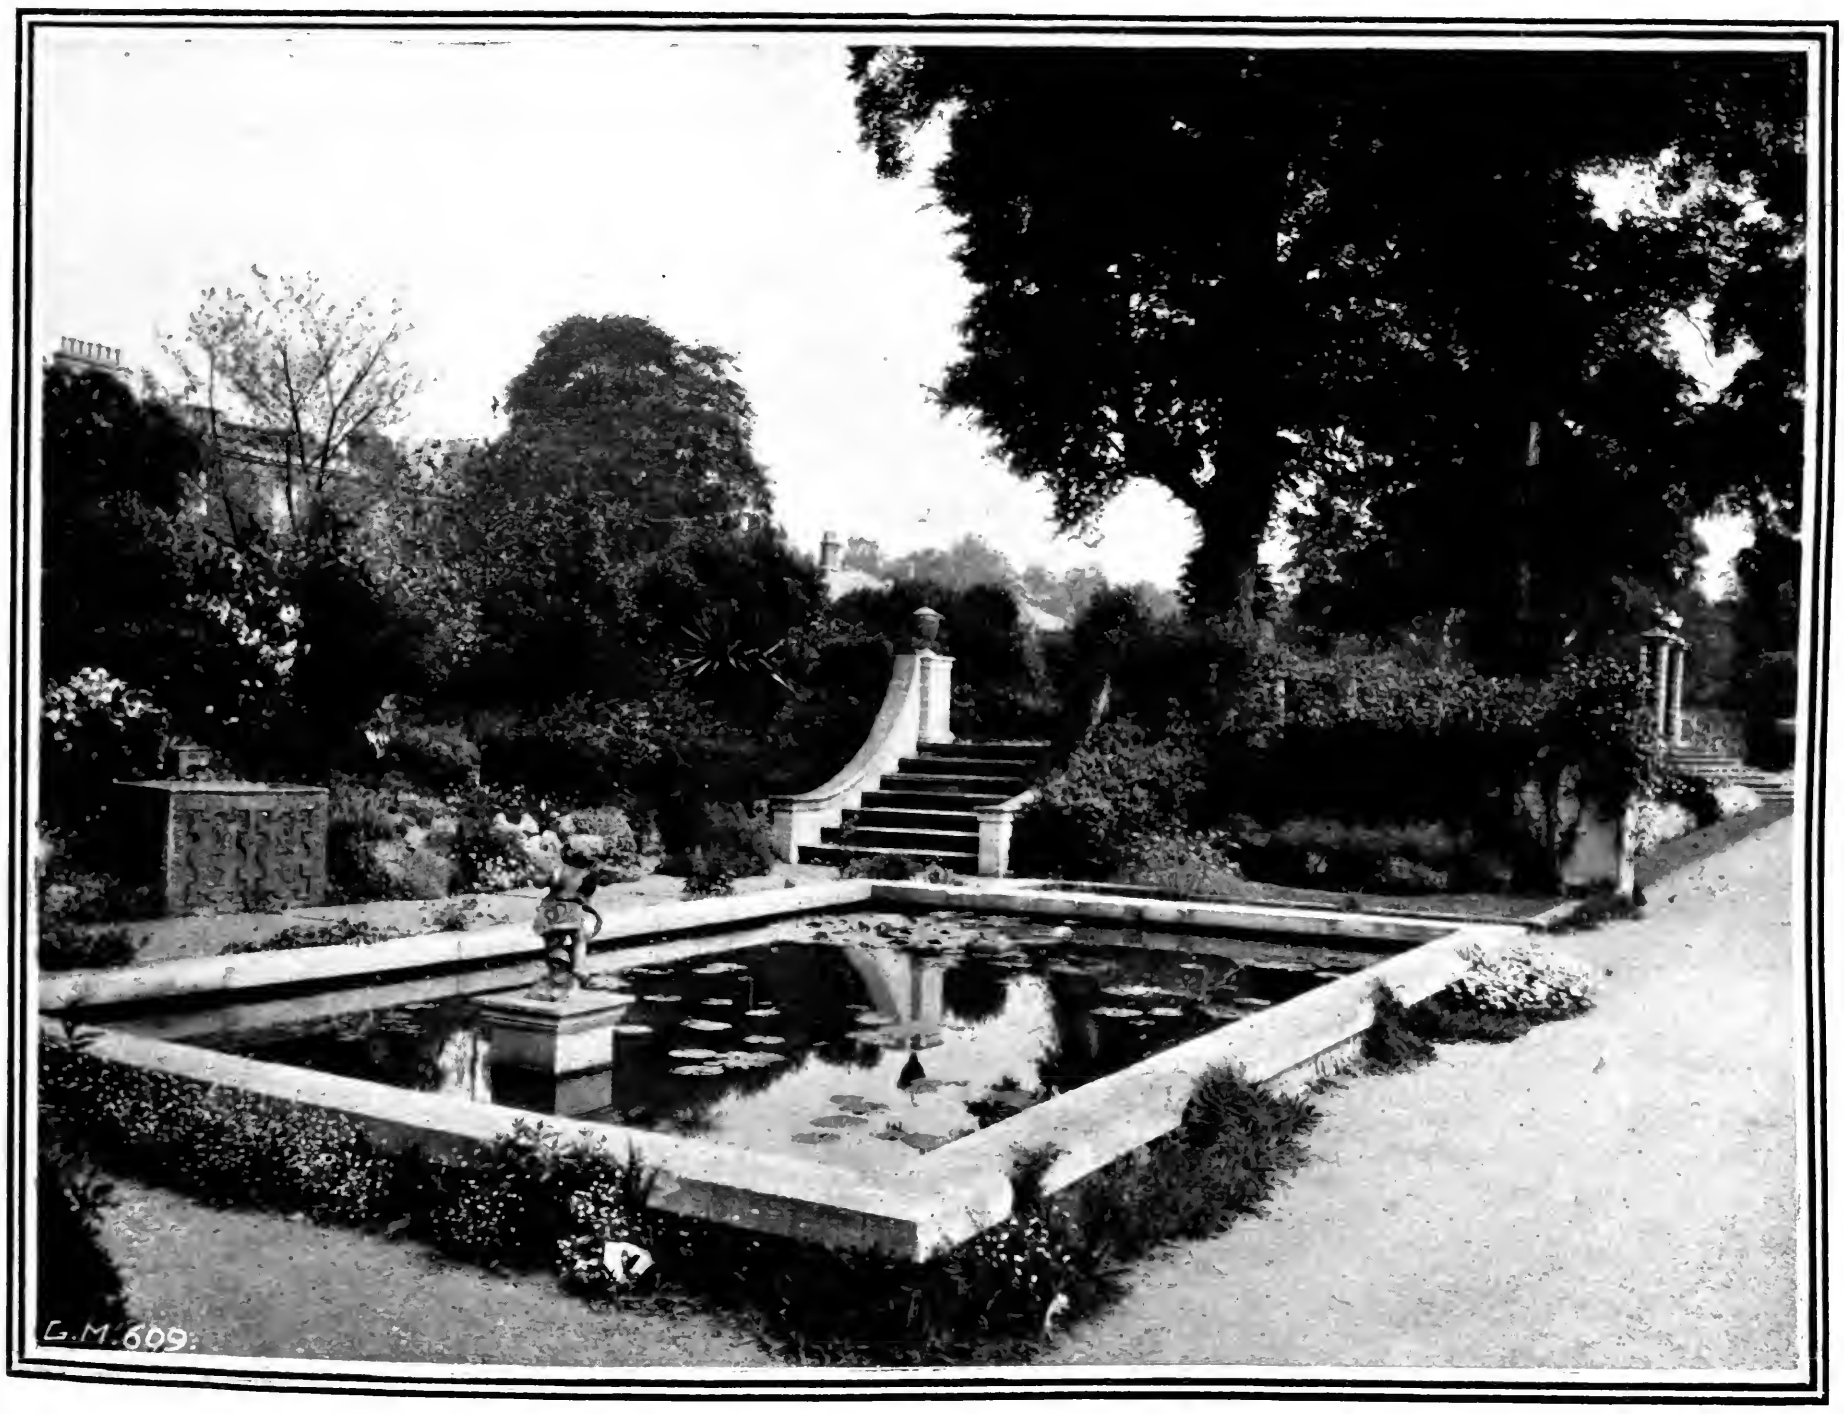
Fruit and Kitchen Gardens.

Inside the enclosure, where fruit and vegetables are grown, the glass structures are located, and perhaps the chief feature here is the up-to-date collection of perpetual-flowering carnations, and the plants are grown remarkably well, for the carnations is one of Mrs. Gordon-Canning's favourite flowers. Another is the violet, and in their season frames near at hand are filled with plants that never fail to bloom freely. There are plant-houses and forcing pits, vineries and peach houses to provide the needs of the establishment, and in final reference to flowers let me add that Mr. Prentice is no mean expert in the culture of sweet peas. In short, the head gardener at Hartpury is an all-round man, and how he manages to keep the household supplied with vegetables from the comparatively small kitchen garden at his disposal is best known to himself; but he does it, and manages to get a few specimens for winning prizes with at the shows as well.

Gardener and employer have co-operated in getting together a choice collection of apples and pears, which are mostly grown as cordons, three of each variety, and a continuous arch of this type of tree over one of the walks is not only effective but productive. Pyramid and bush trees surround the vegetable quarters, and the idea seems to have been to put a fruit tree wherever there was room for one. In the show arena Hartpury is not unknown, for on three occasions Mr. Prentice has won the champion silver cup for the highest number of points gained at the Gloucester Root, Fruit, and Grain Society, and last autumn he exhibited a very creditable display of apples and pears at one of the R.H.S. meetings at Vincent Square.

It only remains to be said that Mr. and Mrs. Gordon-Canning, whose charming es- the West Country, think also of the welfare of their workpeople and those about them, for a cricket club is maintained on the estate, with tea for the players on match days; a reading-room is provided for the use of the villagers, and many other acts of generosity might be recorded. In short, the whole atmosphere of Hartpury is suggestive of a mutual understanding and good feeling between employer and employed and landlord and tenant.

G. H. HOLLINGWORTH.



VIEW IN WATER GARDEN, HARTPURY HOUSE.

Ripening Strawberries.—As the forced fruits change colour remove the plants to a lower temperature, discontinue liquid manure, and give air freely. Plants which are swelling their fruits may be given a night temperature of 60 to 65 degrees; liquid manure, weak guano water and soot water, are all useful at this stage. Later plants in bloom should be kept as near 55 degrees as possible. Go over the blooms each day with a brush to fertilise them, and remove all unnecessary flower spikes, and weak blooms from the trusses as early as possible. Thin the fruits to about nine on each plant, and syringe well underneath and above the foliage to prevent red spider. The present is a good time for those who have little or no convenience for very early forcing to introduce the first batch of plants where they can be kept near the glass. as they will now soon respond and grow freely.—F. JORDAN.

YOUNG DAHLIA PLANTS.

Many dahlia tubers will soon be placed in boxes, or on borders in warm houses, in order to force them on for the production of young shoots for use as cuttings in due course.

Very often the crowns of the old plants which have been stored in cellars and similar places, in leaf-soil, are covered with mildew or mould, and I have seen such produce cuttings which have decayed soon after being inserted, no matter how careful the treatment was.

Tubers stored in clean sand never gave any trouble, the crowns being clean, and the young shoots growing from them formed roots readily. The matter of storing, including position, material for covering, and the risks from fungus, forms a subject on which many of us would like to be enlightened. Experienced cultivators know how to treat the old tubers and the young cuttings from them, so as to secure the best results in the flower garden. But the inexperienced cultivator often unduly forces his plants early in the season, and then he has rows or clumps of weakly, leggy specimens to deal with at planting-out time.

When in the gardens at Lathom House, Ormskirk, under that competent gardener, Mr. James Hathaway, I remember the splendid specimen dahlias which he planted in the centres of some large beds in the flower garden. Only one plant was put out in each bed, and show, cactus, pompon, and single-flowered sections were represented, but every specimen was very bushy, well shaped, and flowered more freely than any I have ever seen elsewhere.

The plants were brought on very slowly, and not subjected to much heat in their early stages of growth. Nearly all cuttings were rooted on a mild hotbed under a low frame.

If the tubers are placed in boxes, covered with a sandy soil, and put on shelves under the roof glass, the resultant shoots will be much stronger, and, in every way, better than those from tubers placed on the borders of newly-started vineries or peach houses.

I am also in favour of inserting one cutting in a deep, narrow pot, rather than five or six in a large pot. The new roots are very fleshy and tender, and when propagated singly in small pots the young plants can be repotted or otherwise dealt with without disturbing the roots. Dahlias deserve to be more grown in large borders than they are in many gardens. The foliage forms a good background to other plants. G. B.

Cestrum Smithi.—The different forms of habrothamnus are now included in the genus Cestrum, although they formerly were, and still are, kept distinct by some. A well-known species is C. elegans, a plant of loose, vigorous growth, and well suited for clothing the pillars or walls of the greenhouse. The flowers of this are purplish-red Another species, namely C. aurantiacum, has orange-coloured blossoms, while in a very desirable garden variety, C. Newelli, they are of a bright crimson colour. C. Smithi, which is also of garden origin, has soft-coloured flowers, and is therefore quite distinct from the others. It is less vigorous than those named above. All grow well in ordinary potting compost, and are but little troubled by insect pests.—K.

BRIDGESIA SPICATA.

In many gardens there are bare walls, or bare places on them, facing north, north-west, or north-east, and, of course, some persons find it a difficult matter to satisfactorily cover these places with suitable plants. Ivies will soon furnish walls in such positions, but many of us do not like to use them if we can obtain other kinds of plants which will serve the purpose equally well.

I was, a few years ago, buying some climbing plants from a well-known nurseryman, and he turned to me, and said, "Why don't you plant some bridgesias on that long north wall?" and added some words of commendation. I did not, at that time, know this plant, but his advice was taken, and several planted. I was astonished at the progress they made. The leaves are deep green, thick and leathery, but not very large; they are set rather closely together and lie rather flat to the wall. The branches, which are numerous, cling to the wall just like ivy; indeed, better than some varieties of ivy, and, altogether, the effect is very pleasing.

Some of the plants did not have much light, as they were grown under the spreading branches of some oak trees, but the leaves retained their freshness. Very little attention is needed in the way of training and pruning—less than is required in the case of ivy. I found that it was best to plant specimens that were young and healthy and growing in pots; some old mortar rubble, added to the border soil, was very beneficial to them. Only old specimens need any manurial surface dressings. B.

KING'S ACRE

UNIQUE NOVELTIES.

LATE FLOWERING EREMURI.

A truly magnificent strain of Natural Hybrids found in Persia at an altitude of 3,000 to 6,000ft., on the Elburg Range.

The LATEST-FLOWERING of all EREMURI

Tulipa Eichleri

Large stock of this grand species, the most beautifully-coloured Tulip in commerce.

Also other Meritorious Novelties from Persia.

New Descriptive Catalogue, with prices, free on application.

KING'S ACRE

NURSERIES LTD.,

HEREFORD.

Rhododendrons.

Crimson, White, Pink. 250 Choice Named Varieties, fine foliage, well budded, for potting or planting. 1 to 1½ft., 1½ to 2ft., 2 to 2½ft., 2½ to 3ft., 3 to 4ft., 4 to 5ft., 5 to 6ft., 6 to 7ft. List of sorts and prices on application; many thousands to offer. Standards in all sizes.

All Home-grown. Inspection Invited.

F. STREET, Heatherside Nurseries, CAMBERLEY

PEARSONS' RELIABLE SEEDS.

MAUD HOLMES.

SWEET PEAS.

After making hundreds of trials of Sweet Peas, and having examined many more hundreds on various seed trial grounds, we make the following selections for the guidance of those who have not had the opportunity to closely study and compare the vast army which is now in cultivation.

THE 12 BEST DECORATIVE SWEET PEAS for 2/6.

	Seeds.		Seeds.
Evelyn Hemus	25	John Ingman	25
Flora Norton Spencer	25	King Edward Spencer	25
Helen Lewis	25	Lady G. Hamilton ...	100
Helen Pierce	100	Nora Unwin	50
Hon. Mrs. Kenyon ...	100	Queen Alexandra ...	50
Mrs. Hugh Dickson ...	25	Othello Spencer	25

The EXHIBITOR'S COLLECTION

12 Splendid Varieties for 5/-; post free.

	Seeds.	Price.		Seeds.	Price.

Giant Cream Waved	25	6d.	Thos. Stevenson	15	6d.

We offer all the choicest stocks of **Vegetable and Flower Seeds** at the **Lowest Profitable Prices.** We feel confident that many amateurs now paying from 25 to 50 per cent. more than we charge would, if they gave us a trial, find the results equally good, and they would have the surplus to spend in other directions. We quote below a few specialities.

Many of our friends and customers having told us that *ounces* of seed were often far more than they required, we have lately, for the convenience of those with small gardens, put up packets at **2d.** and **3d** for their convenience. We also offer nearly all the Hardy Annual Flowers in (liberal) **2d.** packets.

Fully Illustrated Catalogue Free on Application.

PEAS.

Gradus 1/-, Thos. Laxton 1/2, Reading Wonder 1/-, Triumph 8d., Prince of Wales 8d., Autocrat 9d., Prizewinner 1/-, Capt. Cuttle 1/-, Little Marvel 1/-, The Gladstone 1/-. ALL PER PINT.

All the best **BEETS** from **6d.** to **1/-** per oz.

„ **CABBAGES 6d.** to **8d.** per oz., **2d.** per pkt.

„ **LETTUCES** from **6d.** to **1/-** per oz., **2d.** and **3d.** per pkt.

Nearly all the best **ONIONS 6d.** to **1/8** per oz.

RADISHES 2d. to **3d.** per oz.

The BEST TOMATOES.

Best of All (Sutton), the best exhibition variety, **6d.** and **1/-** per packet.

Sunrise (Carter's), the heaviest cropper in cultivation; fruit perfect in shape and excellent in flavour, **3d.** and **6d.** per packet.

Smith's Ruby Cluster, an extremely free cropper; colour, shape and flavour excellent, **3d.** and **6d.** per packet.

Up-to-Date, very short jointed in habit, and extremely prolific. Fruit smooth, medium size, excellent quality, **3d.** and **6d.** per packet.

Kondine Red (Holmes), a wonderful cropper, **6d.** and **1/-** per packet.

ALL THE ABOVE ARE SAVED FROM SELECTED FRUITS.

CHOICE PRIMULAS.

We have a magnificent strain of these. The seed is saved in our own houses, with the utmost care. All seed is 1912 crop, and *certain* to grow if it has a fair chance. Large flowered varieties—**Brilliant King**, intense crimson; **Cannell's Pink**, gigantic flower, peach blossom colour; **Brilliant King**, deep velvety crimson; **Mrs. Robt. Cannell**, lovely white with deep red stems; **Pink Perfection**, pure light pink; **The Duchess**, white, with centre of rosy carmine and yellow eye; lovely **White Perfection**, fern leaved, the largest white. All these in separate packets, at **1/-** per packet. Also mixed, from above varieties, **1/-** per packet. **Stellata Mont Blanc**, and finest mixed, **1/-** per packet. The packets contain about 120 seeds.

A Fine Selection of Seed Potatoes—Scotch Grown.

J. R. PEARSON & SONS, "THE NURSERIES,"

LOWDHAM, NOTTS.

Established 1782.

CULTIVATION OF LEEKS.

There is little doubt that the cultivation of the leek is becoming more popular in England year by year, more particularly the growing of large individual specimens for exhibition, not only by professional, but also by amateur gardeners. The Leek (Allium porrum) was introduced into this country from Switzerland about the middle of the sixteenth century; it is one of the hardiest of cultivated vegetables, which fact is probably largely responsible for its popularity in the colder districts of Scotland and Wales, a popularity which is, therefore, not solely due to the great partiality exhibited by the inhabitants of these countries for vegetable soups. Scotchmen in particular are well acquainted with the method of distilling a savoury soup by boiling an old hen and thickening the broth with leeks and kale. The leek—although classed as a perennial—attains its required proportions as a vegetable in the first year of its growth, and, like the onion, it exhibits a tendency to produce its seed in the first year when early sowings are made that year or during the previous autumn.

As a cooked vegetable I would give preference to the leek over the onion, as it has a mild palatable flavour, and produces less of the distasteful odour which affects the breath after partaking of onions, even in a cooked form. As a vegetable to be eaten in a raw, or uncooked, state, the onion will always hold its own with a certain class of the community, particularly those who favour strong salads.

Soil Requirements.

Leeks will grow in almost any kind of soil, but not to the same degree of strength. In the gardens attached to many of our large unions, or workhouses, extensive areas are devoted to the cultivation of leeks, but here they rarely receive more than ordinary cultivation; the usual practice is to manure and dig in autumn, fork over in spring, afterwards planting out somewhat thickly the plants which have been raised from seed sown in a sheltered border late in the previous autumn, planting being completed by drawing up the soil towards the stems with the hoe. The cultivation of the exhibition leek is quite another matter, and requires skill and judgment, although the elaborate preparations usually advised for onions need not be given. To grow exhibition or well-blanched leeks they must be consigned to a trench similar to that advocated for celery; when one mentions a "trench" it must not be understood that a deep trench is essential. As with celery, serious mistakes are too often made by removing the top spit of soil, working in a quantity of fresh manure with the subsoil, and planting therein the young leek seedlings; the result of this practice is that their growth is restricted. The depth of the trench will entirely depend upon the nature of the subsoil—its fertility and power of retaining moisture. In an old, well-trenched kitchen garden which I visited I measured some trenches in which leeks were growing, and found them to be two feet deep; this was exceptional. While answering their purpose, I have nevertheless successfully grown excellent leeks in trenches six inches deep. This was in a piece of ground adjoining a river where the water level was within eighteen inches from the surface. While being a gross feeder, the leek prefers a well-decomposed or fermented manure to one that is in a raw state, as freshly-made farmyard manure; a liberal dressing of such manure should be incorporated with the soil in the bottom of the trench.

Sowings and Planting.

It is not a wise practice to sow all the seed too early, as frequently seed sown early in January will result in an undue proportion of plants running to seed. Main crop sowings may be made in boxes under glass throughout February and March. Before planting see that the plants have been well hardened off otherwise they will not retain their erect position when planted out, in consequence of which their growth will be arrested. It is important that the roots of the seedling leek are firmly embedded in the weathered soil, and before planting it is always well to rake a little of this into the trench. The trench need not be more than eighteen inches wide for a single row of leeks, and two feet where it is thought preferable to grow a double row. The leeks should be planted about three inches deep, and about one foot apart, taking care to spread out the roots; as these are very long and numerous they should be taken out of the boxes with as much soil as possible attached to them. If the soil in the trench is of a loose and porous character it should be well trodden before the operation of planting is proceeded with.

Blanching.

As the object of the cultivator is to secure long and proportionally stout blanched stems, this can only be acquired by adopting some artificial means of blanching. I have been able to perform this by means of a stout brown-paper collar placed round each plant; the paper tubes used for enclosing plans, or for like purposes, are admirable, and can be cut down to a convenient length. The leaves must always be allowed freedom, and as the stem becomes gradually drawn up, so must the collar be raised, and the soil drawn around the base of the plant. By the middle of July the plants will be fully blanched, after which the stem will increase in thickness. One season I tried blanching a row similar to the method adopted for celery, but was not successful in securing so long a stem as was possible when the collar was used; also when the plants were dug up considerably more washing was necessary. A point in favour of the earth-blanched leeks was that of colour, which was infinitely whiter than those blanched with the paper; this may not, however, be the experience of other growers.

Liquid Manures.

The crop must receive other sources of nourishment besides that provided from the soil, and this is best supplied to it in the form of manurial stimulants. Having an unlimited supply of liquid manure or drainings from stable, cowshed, and piggeries at my disposal, I can find no better form of liquid manure than this when properly diluted with at least five parts of rain water; this may advantageously be applied twice a week during the growing season, except when heavy rains are frequent. Often some of the strongest plants will throw up their flower spike towards the close of the season, and this should be pinched out immediately it appears.

The General Crop.

Very useful crops of leeks can be grown on well-manured soil by dibbling the plants out in shallow and narrow furrows eight to twelve inches apart, and six inches from plant to plant. Planted thinly no vegetable presents a more skeleton-like appearance in the rows; they look as though they will not occupy the space allotted to them to advantage. Plant out the seedlings when the ground is moist, using an iron-shod dibber with which to make a hole deep enough to allow the roots to go straight down to admit of the plants being buried up to their collars, or to the base of the leaves. Finally the soil should be pressed down around the stems and over the roots, and a watering given if the soil is dry. After cultivation consists of frequent stirrings of the ground between the plants, later drawing it up around them on each side of the row. The leek is very serviceable for winter use if dug up and stored in dry soil; during the winters, in which green vegetables suffer severely from frost, leeks thus preserved are invaluable.

Of varieties, Ayton Castle Giant, Lyon Selected, Prizetaker, Royal Favourite, and Musselburgh Improved, are all worthy of cultivation. J. C. N.

APONOGETON DISTACHYON

This charming water flower is an almost continuous bloomer. In the south-west it has been noted in blossom in ten out of the twelve months, and expanded flowers might doubtless have been discovered during the two remaining months. Naturally the plants in question were growing under varied conditions and localities, and in some cases were bearing but a solitary open blossom, while in others they were white, with hawthorn-scented bloom. One valuable property of this Cape Pond Weed is that it will succeed in far deeper water than will nymphæas, for in some of the beautiful South African rivers in the forest region of Zitzikama and Knysna it may be seen growing in pools fully 10ft. deep. Here, on the clear brown water the floating, white blossoms and lance-shaped leaves are thrown into charming relief, though they have, perhaps, to yield the palm of loveliness to the blue water lilies that blossom in the shallower reaches of the same rivers. The manner in which the plant propagates itself by its floating seeds is very interesting, and is another instance of the infinite solicitude of Nature for the reproduction of her flowers. Aponogeton distachyon is quite hardy in the South of England, and is seldom, if ever, injured by the frost. WYNDHAM FITZHERBERT.

Primula Kewensis.—It is strange that after being wanting in fertility for so long seeds of this beautiful primula can now be readily procured. This has led to its greatly extended cultivation, for, as a winter-flowering plant it is now much appreciated. The variety farinosa is quite distinct by reason of its mealy character.—S. W.

Cyrtanthus lutescens. — This, the first of the small-growing cyrtanthi to unfold its blossoms, forms a very pretty feature in the greenhouse; that is, where several bulbs are growing in one pot or deep pan. The flower scape, which reaches a height of about fifteen inches, is terminated by an umbel of pale yellow blossoms, curved-tubular in shape, and about two inches long. Others of this section are C. McKeni, white; C. angustifolias, light red; and C. McOwani, of a deeper hue, as well as some garden forms classed under the head of C. intermedius. All these cyrtanthi are easily grown, and their flowering period is not limited to any one period of the year, though the largest number of blossoms are borne during the late winter and spring months. —T.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CYMBIDIUMS.—The different species and the many hybrids now in cultivation have made cymbidiums not only attractive, but exceedingly useful, for cultivation generally in gardens. There certainly are no orchids more serviceable in cool ferneries and conservatories; not only are the flowers attractive and in most cases exceedingly durable, but the foliage when the plants are out of flower is usually elegant. C. Tracyanum, C. Mastersi, and C. Winneanum will have recently flowered, and, as new roots will be found to be active, any repotting necessary may be attended to at this period. We find the plants do well in a compost of equal portions of fibrous yellow loam, peat, and sphagnum moss, with sufficient sand, broken crocks, or charcoal, added to render the compost porous. Press the compost moderately firm, and water as soon as repotting is completed. Protect the plants from strong light for a few weeks, and if the outside conditions are favourable spray them overhead; be careful not to over-water at first, but after the plants have become rooted into the fresh compost more liberal treatment may be given. Most of the species and hybrids will be developing their flower scapes, and these must now have abundance of root moisture, and should not, under any consideration, be permitted to become dry. In fact, thoroughly established plants should at all seasons be afforded an ample supply of root moisture. With the exception, perhaps, of C. eburneam, the whole of the cymbidiums may be grown in a cool intermediate house, where the normal temperature in winter is about 55 degrees. C. eburneum requires slightly warmer conditions, and should at all seasons have ample atmospheric moisture.

SOPHRONITIS GRANDIFLORA. — During the past week importations of this beautiful winter-flowering orchid have been distributed, and, although it may be somewhat outclassed in point of size by the hybrids that have been derived from it, none of its offspring can be compared to it in vigorous constitution, brilliance, and free-flowering characteristics. There is nothing more cheery in our houses than well-grown plants, freely flowering in the depth of winter. They are best grown several together in shallow pans, so that they may be suspended near the roof glass; see that the pans are well drained, and use a compost of peat, osmunda fibre and chopped sphagnum moss, pressed moderately firm. Established plants that require repotting are best attended to immediately they pass out of flower. The flowers are produced with the advancing growth and the new roots make their appearance almost immediately after the plants finish flowering. They do best in the cool intermediate temperature.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

DRACÆNAS.—These should have been kept somewhat drier at the roots during winter, or probably some of the roots will be found in a decayed condition, and the lower foliage consequently lost. Leggy plants may be used for propagation by ringing, similarly to crotons. Useful plants may be repotted, a good drainage being essential, and a suitable compost consists of two parts peat to one of fibrous loam, with plenty of sand. Use the syringe whenever the weather permits to maintain a moist atmosphere. They may also be propagated by inserting pieces of the stem containing several eyes, or by inserting the tuberous roots taken from those potted in pans containing a sandy soil, plunging them in the propagating frame until growing freely.

APHELANDRA ROEZLI.—This is a very pretty winter-flowering stove plant. To obtain bushy plants it is necessary, after flowering, to remove the flower spikes, and when growth commences reduce the old ball, potting up in a mixture of two parts light, fibrous loam to one part each of peat and sand. Syringe occasionally, but water carefully until well rooted, when, if necessary they may be shifted into larger pots. It may be propagated by means of cuttings taken from the young growths, or by seeds; one-year seedlings in small pots make useful plants, each carrying one spike of orange-scarlet flowers.

FRANCISEAS.—These are very pretty stove evergreen, flowering shrubs. After flowering the plants, which will grow to a large size, should be placed in a stove temperature, syringed frequently, and kept moist at the root. When growth commences necessary repotting or top-dressing may receive attention. When growing freely they should be pinched occasionally to secure nice shapely examples, and when growth is finished, place them in cooler quarters, and give rather less water until required to flower, when they may again be transferred to a warmer house. Cuttings of the young wood with a slight heel will root readily.

STOVE CLIMBERS.—Where the rafters or trellisings in the stove are covered with climbing plants, growth will now be fairly active, and from the first good growths, just sufficient to cover the space, should be selected, removing superfluous and weakly growth at once. This applies especially to such plants as stephanotis, ipomæas, dipladenias, Hexacentris mysorensis (Thunbergia), and Cissus discolor. Where mealy bug or scale exists, especial care must be taken to keep the plants clean, or they will necessarily be robbed of their health and beauty. H. PRIME, Hatfield House Gardens.

THE FLOWER GARDEN.

SEEDS of many subjects which are used for the flower garden during the summer months should now be sown. Among these are lobelias, antirrhinums, nicotianas, salvias, ageratums, pyrethrum, salpiglossis, petunias, verbenas, fibrous-rooted begonias, etc. These should be sown thinly in pans or shallow boxes, and afterwards placed in a house or pit where a temperature of 50 to 55 degrees is maintained; here germination will quickly take place, providing due attention is given to watering and shading, the latter a most important matter in raising seeds successfully, but one not often fully regarded by inexperienced and careless hands. Soil containing the seeds should be kept moist during the period of germination, and also well shaded in bright weather; pieces of glass laid over the pans and boxes check evaporation, and support the paper or other material used for shading purposes. As soon as the seedlings appear they should be given a light position near the glass, and be kept a trifle dry to prevent damping; if damping is detected the seedlings in the affected pan should be immediately pricked out, as this course is usually effective in checking the trouble.

DAHLIAS.—Where the practice of raising dahlias annually for planting out is adopted, preparations must be now made to obtain cuttings. The old roots which have been stored away since autumn should be examined; cut away any decaying parts, and afterwards box or pot the plants. These will soon throw up growths suitable for cuttings, if placed in a warm house and kept moist. To prevent the growths becoming unduly drawn and spindly give them as much light as possible. Look over the stools every few days when growth is active, taking off the cuttings with a heel, inserting them singly in small pots, and placing them in a propagating pit, having a moderate temperature, where they will soon take root. When well rooted the young plants must be potted into 48-sized pots, and in these they will be of a useful size for planting out at the end of May. Salvia patens can also be successfully treated in the same manner whenever it is desirable to increase the stock of this useful bedding plant.

LAWNS will now require renewed attention; the wet, mild weather experienced so far through the present winter has been exceptionally favourable to the growth of moss and weeds amongst the grass, and steps must be taken to eradicate these. A good raking with a fine-toothed iron rake will remove a great deal of the moss, and this process should be followed up with a good top-dressing of wood ashes and soot, which will encourage a healthy growth of grass and prove detrimental to the moss. Weeds can be removed by grubbing, and this method is the most satisfactory one when dealing with deep-rooting kinds. Lawn sand is effective in getting rid of small weeds if applied during warm, dry weather later in the season.—T. B. FIELD, Wych Cross Place Gardens.

FRUITS UNDER GLASS.

FIGS.—Pot trees that have been subjected to a steady bottom heat of 75 to 80 degrees will, in most cases, have fully developed their foliage, and the embryo fruits should be swelling freely. As the days lengthen we can reckon on more sunlight, and more moisture may be afforded in the shape of damping and syringing. To prevent fruit dropping, see that the trees are never allowed to feel the pinch of dryness at the roots. From healthy trees remove all superfluous and ill-shaped fruits before the flowers open, as by this means dropping of fruits is reduced to a minimum. Pinch the shoots at the fourth or fifth leaf to guard against overcrowding. Planted-out trees should, as far as possible, be grown on the extension system, and the superfluous wood removed in the winter. As soon as the fruits begin to swell increase the night temperature to 65 or 68 degrees, allowing a day temperature of 85 degrees or more with sunheat. Liberal supplies of liquid and artificial manures may be given to pot trees, and those in shallow borders, but guard against encouraging gross growth, which is not conducive to fruit production. Keep later trees quiet for another month.

EARLY VINES.—The recent severe weather with cold easterly winds has made it necessary to bestow extra care and attention in the ventilation of early vineries. A little air should, however, be admitted early in the day and at night if possible, in order to encourage a strong, healthy growth, and to carry off excessive moisture. Liberally feed, and take advantage of bright days to forward the crops of pot vines, as well as early permanent vines, but do not insist on too high a night temperature during cold nights; be content with 63 to 65 degrees, and give 5 degrees more in mild weather.

MIDSEASON VINES.—Disbud these as soon as they become ready, and keep the shoots clear of the glass, but do not trouble about getting the shoots into position, as later, when the vines are in flower, they may be tied down without much fear of injury. Remove all surplus bunches, and thin all free-setting varieties as soon as possible; attend to stopping and pinching, always bearing in mind that good, healthy leaves are preferable to lateral growths. Close later houses which contain mixed varieties, to obtain ripe grapes during July and August.

YOUNG VINES.—There is still time to put in vine eyes where young vines will be required for planting in June or July, after the present crop is cleared. Select buds from wood that is firm and well ripened.—F. JORDAN, Warter Priory Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The annual general meeting of this society was held at the Royal Horticultural Hall on Tuesday, February 11, at 3 p.m. There was a good attendance, and the President, Sir Trevor Lawrence, presided. Among those present we noticed Sir Harry J. Veitch, Sir Albert Rollit, Sir J. T. D. Llewelyn, Messrs. J. Gurney Fowler, E. A. Bowles, J. Hudson, V.M.H., A. W. Sutton, V.M.H., H. B. May, V.M.H., G. Gordon, V.M.H., Owen Thomas, V.M.H., N. N. Sherwood, V.M.H., W. A. Bilney, C. E. Shea, F. Herbert Chapman, J. Green, C. Fielder, C. Nix, R. H. Pearson, W. B. Cranfield, C. H. Curtis, W. Wood, T. Bevan, R. J. Frogbrooke, J. H. Dick, F. W. Harvey, E. Burgess, etc.

The notice convening the meeting having been read, the minutes of the previous annual general meeting were also read and signed. Thirty-six new Fellows were elected.

The President said that the annual report and balance-sheet had been in the hands of the Fellows some time, and so would be taken as read. In making a few comments he referred to the splendid International Horticultural Exhibition at Chelsea in May last, and the visit of their Majesties the King and Queen on that auspicious occasion. It was gratifying to know that the great exhibition was a financial success, and the gardening charities would benefit greatly as a consequence. His reference to the honour of knighthood conferred upon Sir Harry J. Veitch was loudly applauded.

Sir Trevor pointed out that the establishment of a diploma in horticulture marked a great step in the advancement of the art of gardening, and in the work of the society. The scheme for such a diploma had been approved by the Board of Agriculture. This recognition of horticulture at the instance of Mr. Walter Runciman was, the President considered, a distinct move in the right direction. He also pointed out that the University of London had under consideration the subject of a Degree in Horticulture.

Kindly reference was made to the absence, through illness, of Mr. Wm. Marshall, V.M.H., and the President stated that there were three vacancies in the list of Victoria Medallists, and these were to be filled by the appointment of Mr. Jas. Whitton, Superintendent of the Glasgow Public Parks; Mr. W. H. Divers, of Belvoir Castle Gardens; and the Rev. W. Wilks, the society's secretary. Sir Trevor then made special reference to the invaluable services rendered the society by the Rev. W. Wilks, who had now completed 25 years' service as secretary. A fund had been raised (£500 already contributed) to show some recognition of these admirable services. It was proposed to have a portrait of Mr. Wilks painted and hung in the council room; a substantial cheque would be handed him in due course, and a beautiful large solid silver salver was then handed to Mr. Wilks amid great applause.

Sir Trevor then spoke of his twenty-nine years' service as president of the society, and said it had been one of the greatest pleasures of his life to be so long associated with gardeners and gardening. He had now arrived at more than four-score years of age, and he felt that it was time a younger man should fill the office. He wished to retire as soon as the council had obtained a successor. Sir Trevor paid a high tribute to the splendid services rendered to the society by the members of council, the excellence of the society's officers, and the work of the many expert members of the various committees.

In seconding the motion for the adoption of the report and balance-sheet, Mr. J. Gurney Fowler (treasurer) reviewed the finances of the society, and there was a round of applause when he said the profits for the year were over £9,000. A considerable sum had been invested, and a good amount had been spent on books for the Lindley Library, and for binding books that needed that attention.

No one offered any comments, everybody appearing to be highly satisfied with the progress made. The motion was put and carried.

The Rev. W. Wilks, V.M.H., said it was difficult for him to express his feelings of thanks and gratitude for the many kindnesses he was receiving, and, indeed, had received, during the whole of his connection with the society. He was proud to know that no single society had made such progress as theirs, a phenomenal progress due to development of a love for hardy flowers, a change of policy on the part of the society, from pleasure to practical horticulture, and to the splendid work of their devoted president, and a council that was united in its efforts to advance horticulture—and only once during the past twenty-five years had there been the slightest antagonism among its members. Year by year the society had paid increased attention to scientific horticulture; they had a well-equipped school of horticulture at Wisley, and now their efforts had been recognised by Government, and, in conjunction with the Board of Agriculture, a diploma of horticulture had been established, and this he considered would make a great, and not yet fully understandable, difference to the position of horticulture in the United Kingdom. He expressed his thanks for the silver salver presented to him by the President, for the promised cheque, and especially for the high honour of the Victoria Medal of Honour in Horticulture.

The officers and council were declared elected in accordance with the notice in the annual report. Great regret was expressed at the absence of Lieut.-Colonel Sir George Holford, who had sustained a rather severe accident in the hunting field, and the meeting then concluded with a vote of thanks to the President for presiding, moved by Sir John T. D. Llewelyn, Bart., and seconded by Mr. A. W. Sutton.

SCIENTIFIC COMMITTEE.—February 4.

Present: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair); Messrs. R. H. Curtis, A. Rolfe, W. Hales, G. Wilson, A. Worsley, G. Massee, Sir H. J. Veitch, and F. J. Chittenden (hon. sec.).

LÆLIA LUNDI (Reich. and Warm).—Mr. R. A. Rolfe exhibited, on behalf of Messrs. Sander, a plant of this dwarf Brazilian species, remarking that it is allied to L. Regnelli, but is easily separated by its habit of flowering on the undeveloped growth, a character which it shares with Cattleya Walkeriana. The leaves are narrow and fleshy, and the flowers solitary, pale lilac with a veined blotch on the front lobe of the lip. It is quite unlike any other lælia in cultivation. Its history is given in the "Orchid Review" (xviii., p. 62).

ONCIDIODA COOKSONIANA.—The Orchid Committee referred the plant of Oncidioda Cooksoniana to this committee. It had been exhibited by Messrs. Charlesworth. The cross is a rather curious one between Cochlioda Noezliana and Oncidium macranthum, and the hybrid has something of the long raceme of its pollen parent, while the flowers are larger than the seed parent and somewhat different in colour. It was first raised by Mr. N. C. Cookson. A Botanical Certificate was unanimously recommended to the plant.

CROCUS BIFLORUS WELDENI.—Mr. Bowles showed a seedling from Messrs. Barr of this form with a distinct sulphur tinge. He found that seedlings of chrysanthus and biflorus ran into one another so as to render it impossible to regard these as anything but forms of a single species, as, indeed, Herbert had regarded them, grouping them under the name of C. annulatus. C. chrysanthus gave blue seedlings similar to those of C. biflorus in colour.

BITTER PIT IN PEAR.—Some pears were shown with brown spots in flesh, similar to those frequently seen in apples. This spotting is not the product of the attack of any specific organism, but is due to some derangement in the normal development of the fruit. Mr. Massee recognised the spotting of the pear flesh as of similar origin.

Scottish Horticultural Association.

The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on February 4. There was an attendance of 95 members.

Mr. Massie, the retiring president, occupied the chair at the commencement of the proceedings, and, after the formal business of the evening had been transacted, introduced his successor in the office, Mr. David King, who thereupon took the chair and delivered his inaugural address, taking as his subject, "Recent Advances in Horticulture." In his introductory remarks Mr. King referred to the general policy which he thought ought to be pursued in the current year. As they were all aware, in the two years of his predecessor's occupancy of the presidential chair, very considerable changes, for the most part due to his initiative, were brought about. Now he thought it would be inadvisable to make any more drastic changes for the present. In fact, he thought little more change would be necessary for some time to come. He thought the aim should be to work upon the foundation already laid, and develop the plan of operations which had been so well set out. But, at the same time, there must be no relaxing of effort; there must be no faltering. He would do his best, but that was not enough. The members of the association must also do their part. Everyone could do something in his or her own way, and if, for example, every member were to bring in even one new member yearly, what a difference it would make! This was surely not beyond the powers of anyone, and he trusted that no effort would be spared to increase the membership as much as possible, for unless this was done prosperity could not be continued.

Reference was made to the discussions at the meetings. It had been repeatedly urged that the younger members of the association should take a larger share in these discussions, but there seems still to be great diffidence amongst them. Mr. King hoped they would shake this off, and take their proper part in these discussions. It had been decided to have an evening for papers by juniors in the current session, for which he would be very pleased to continue the prizes offered in the two past sessions. He proposed to offer a gold medal for the first prize paper, and book prizes to the two which rank next in merit. On the motion of Mr. John Phillips, Mr. King received a very cordial vote of thanks.

The exhibits were: Collection of tulips, including the variety Coronation, from Mr. King; hybrids of Primula obconica, from Mr. D. W. Thomson, Edinburgh; newer varieties of perpetual-flowering carnations, and Phœnix Roebelini, said to be the best palm for ordinary dwelling-house decoration, from Messrs. Todd and Co., Edinburgh; flowers of Pyrus japonica, Galanthus Elwesi, and G. nivalis fl. pl., and Helleborus niger maximus, H. orientalis Albin Otto, H. abschasicus grandiflorus, and H. caucasicus purpurescens major, all from the open air, from Mr. C. Comfort, Broomfield, Davidson's Mains; and Richardia africana, from Miss Burton, Polton. There was also exhibited an improved tool for sampling soil, planting potatoes, bulbs, etc., from Mr. John Mack, Edinburgh.

At the meeting on March 4 a paper will be read on "Dry-wall Gardening," by Mr. Thomas Smith, Coombe Court Gardens, Kingston-on-Thames.

Royal Gardeners' Orphan Fund.

The annual meeting and election of this beneficent fund was held at Simpson's Restaurant, 100, Strand, W.C., on February 7, 1913. Mr. H. B. May, V.M.H., presided, and proceedings commenced a few minutes after 3 p.m. The necessary preliminaries were soon disposed of, and then the report for 1912 was read.

REPORT OF THE COMMITTEE FOR 1912.

The general tenor of the report on the operations of the Fund during the past year which the committee has to present to the subscribers, is again of a satisfactory character, inasmuch as the contributions from all sources show a slight increase. This is the more gratifying because the increase is due to a larger measure of support in the form of annual subscriptions. In common with most other institutions which make their annual appeals in May, the Fund severely felt the effects of the national appeal then being made on behalf of the widows and orphans of the victims of the awful "Titanic" disaster, but the position was happily retrieved later by contributions from other sources. The expenditure side of the accounts again shows an increase in the amount disbursed in weekly allowances to the children, while an appreciable reduction in the working expenses has been brought about, without adversely affecting the efficiency of the management.

The number of children receiving the full benefits of the Fund at the commencement of the year was one hundred and seventeen, and twenty-eight candidates waiting for election—all in sore need of assistance—were in receipt of compassionate allowances. Of this number eighteen were elected to receive the full allowance at the annual meeting, and grants in aid were subsequently made to the twenty-five candidates who are appealing for election at this meeting. During the year twelve children ceased to receive aid from the Fund, and nineteen children — the greatest number that the committee can prudently see their way to provide for—will be elected on February 7. The total amount disbursed in allowances during the year was £1,796 10s., bringing up the amount distributed under this heading to the grand total of over £26,542.

The annual Festival, held on May 8, under the genial and extremely sympathetic presidency of Sir Edwin Durning Lawrence, Bart., again proved a most enjoyable function, a large company being present, including all the well-known supporters of the Fund and many visitors. The collection amounted to nearly £1,000, and the chairman munificently headed the list with one hundred guineas. Mr. Sherwood and his sons again showed their keen interest in the welfare of the Fund by contributing one hundred pounds; while Messrs. Sutton and Sons also contributed a most generous donation. Your committee desires to express their deep gratitude to Sir Edwin Durning Lawrence for the valuable services he has rendered to the Fund, and has pleasure in inviting the subscribers to add his name to the list of vice-presidents.

The committee acknowledges with much gratification the receipt of the sum of £266 16s. 4d., the proceeds of a collection made to perpetuate the memory of the late Mr. Peter Barr. Your committee greatly rejoices that a lasting memorial of this distinguished horticulturist—known the world over as the Daffodil King—should be associated with the Royal Gardeners' Orphan Fund, which he helped so materially to establish, being a member of the original committee.

The receipt of a legacy of £100, left to the Fund by the late Mrs. Ann Pollett, widow of Mr. Henry Montague Pollett, founder of the old-established horticultural printing business of Messrs. H. M. Pollett and Co., and for some years a much respected vice-president of the Fund, is also gratefully acknowledged.

The warmest thanks of the committee are again most heartily accorded to the stewards at the annual dinner; to the honorary local secretaries—and especially Mr. Carver, Mr. Neve, and Mr. Rowe—whose kindly efforts to increase the list of annual subscribers have been most successful; and to the committees of the Altrincham Gardeners' Association, the Bradford Chrysanthemum Society, the Reading Gardeners' Association, the Chislehurst Gardeners' Society, the Sevenoaks Gardeners' and West Kent Chrysanthemum Society, the Tonbridge Gardeners' and Amateurs' Society, the Leeds Professional Gardeners' Club, and the Spen Valley Gardeners' Society, who, by means of concerts and other forms of entertainment, and the sale of flowers at exhibitions, have rendered the Fund most valuable help. The committee would greatly rejoice if other local committees would give a thought to the needs of the Fund and render it some assistance by similar means. They would also specially commend the objects of the Fund and the valuable work it is doing to the members of Gardeners' Improvement Societies, who, by means of card collections among themselves, could render most valuable assistance.

With very sincere regret your committee deplores the loss by death during the year of a greater number than usual of valued friends and constant supporters of the Fund. In its early days the Fund received substantial help from the late Mr. Herbert J. Adams, one of the oldest of the Vice-Presidents; and from first to last it has had no more constant advocate of its claims to support than the late Mr. Alexander Dean.

The committee desires most cordially to thank the auditors, Mr. P. Rudolph Barr and Mr. Frank Reader, for their exhaustive examination of the accounts now presented. Mr. Barr is the retiring auditor, and the committee has special pleasure in recognising the value of his past services by recommending him to the subscribers for re-election.

CASH STATEMENT FOR 1912.

Having inspected the securities and examined the books and vouchers supplied to us, we hereby certify the above account to be correct.

P. RUDOLPH BARR, FRANK READER, } Auditors.

January 13, 1913.

Mr. May moved the adoption of the annual report, and expressed his pleasure at being able to state that annual subscriptions had increased, expenditure had slightly decreased, and the amounts dispensed to orphans on the funds, and also grants in aid, especially when the children were being launched into working life, was larger than ever. The Festival dinner was a pleasant and satisfactory function. Over £250 had been received from the Barr Memorial Fund, and a legacy from the late Mrs. Pollett had added materially to the funds. Not a few friends had been lost to the Fund, notably Mr. H. Adams and Mr. Alex. Dean, who had died since the previous annual general meeting. Mr. Bates seconded the motion, and it was put and carried.

Thanks were accorded to Sir E. Durning-Lawrence for presiding at the Festival dinner, and he was elected a vice-president on the motion of Mr. G. Gordon and Mr. R. Cuthbert. Mr. Edward Sherwood was very heartily re-elected as treasurer on the motion of Mr. Howe and Mr. R. Hooper Pearson. Mr. Barr was re-elected auditor on the motion of Mr. Pearce and Mr. Wallace. Messrs. A. R. Allan, W. H. Cutbush, G. Gordon, D. Ingamells, J. F. McLeod, R. H. Pearson, H. A. Wright, and Mr. Metcalfe, were elected members of committee, the latter filling the vacancy caused by the retirement of Mr. E. Rochford; Mr. Gregory and Mr. Lyne were their sponsors.

Mr. B. Wynne's re-election as secretary was carried on the motion of the Chairman and Mr. Ingamells. Messrs. Bates, Cutbush, Howe, Ingamells, Cuthbert, and Moorman were elected scrutineers of the ballot, and the meeting was then adjourned for the declaration of the poll.

There were about two dozen members present at the earlier part of the proceedings.

On the reassembling of the meeting after the adjournment, the scrutineers presented their report on the result of the ballot, which stated that the following candidates had received the largest number of votes, namely, Edna M. May, Eric A. Lindekvist, Bertha B. Mason, Dorothy M. Mitchell, Wallace Titheridge, Ivy I. Appleford, Sylvia D. Collins, Grace E. Cronchman, Jessie L. Deadman, Elizabeth M. Dodd, Wilfred E. Goff, Margaret E. Jennings, Sarah J. Lee, Ethel E. Miller, Percy G. Peerless, Ida E. Piper, Margaret Riley, Margaret D. Steptoe, and Marion D. A. Woollett. The Chairman having declared that these candidates had been duly elected to the benefits of the Fund. Sir Harry Veitch, V.M.H., expressed the hope that it might be possible to place the unsuccessful candidates on the fund. The Chairman said the committee would not raise any objection to this being done, and Sir Harry Veitch accordingly proposed that the six unsuccessful candidates be elected. This motion, having been seconded by Mr. Moorman, was submitted to the meeting, and was carried unanimously. The customary votes of thanks to the scrutineers and chairman brought the proceedings to a close.

In the evening the members and friends of the fund, to the number of about thirty, dined together at "Simpson's" under the presidency of Mr. H. B. May, and spent a pleasant evening.

National Vegetable Society.

Under the presidency of Mr. Owen Thomas, V.M.H., the annual meeting of this society was held at the R.H.S. Hall, Westminster, on Tuesday, February 11, at 2.30 p.m. Those present were Messrs. O. Thomas, V.M.H., G. Gordon, V.M.H., H. J. Wright, F. W. Harvey, J. Harrison Dick, E. Burgess, Whipaine Nutting, R. Pinches, W. Giles, C. H. Curtis, and E. Quick.

Following the minutes of the previous meeting, the annual report was read by the hon. secretary. This reviewed the work during 1912, referred to the excellent series of trials of vegetables held by the society, the splendid exhibition held at Watford, the fine efforts made to extend vegetable culture by the late Mr. Alex. Dean, and concluded with an expression of thanks to the secretary and treasurer, and regrets that, owing to the lack of support on the part of the general

public, the committee had no option but to wind up the society. The income for the year left a balance of £4, but later donations brought up the balance to £8 11s. 1d.

Mr. Owen Thomas moved the adoption of the report, and said that the society had done a great deal to show the general public the great variety and excellence of British-grown vegetables. The society had at least done one good thing, i.e., by its institution it had forced the Royal Horticultural Society to take a greater interest in vegetable culture, and establish an annual exhibition, which he hoped would prove a continued success. Mr. G. Gordon seconded the motion, and it was passed regretfully. The treasurer's statement was presented and accepted, and the meeting voted the small balance to the hon. secretary by way of honorarium for his admirable services. Mr. Quick expressed his thanks, and regretted that there seemed no other course than to bring the society to an end. Thanks were accorded to the hon. treasurer, Mr. H. J. Wright; to the auditors, Messrs. Pinches and Wilson; to the committee, and to the chairman for presiding. So, for the present at least, the National Vegetable Society finishes its labours.

Royal Scottish Arboricultural Society.

The annual business meeting of this society was held in the Queen's Hall, No. 5, Queen Street, Edinburgh, on February 7. Sir John Stirling Maxwell, the president, was in the chair, and there was an attendance of sixty members.

The report by the Council stated that, although considerable progress had been made in the course of the year, in some respects the results had been disappointing. A further concession as regards death duties on woodlands had been made by the Budget of last year, and now, on the death of an owner, the value of the timber is added to his other estate for the purpose of ascertaining the rate of duty, but the duty is charged on the timber when cut, at the same rate as it is charged on his other estate. It was also stated that, in order to convince the people of the Western Highlands, among whom considerable opposition and prejudice against forestry existed, the Council had appointed a committee to consider the subject with a view to convincing them that, instead of being antagonistic to their interests, forestry would prove a great boon to them. As regarded the Department of Forestry, which Lord Pentland had promised as an integral part of the administration of the new Board of Agriculture for Scotland, Mr. M'Kinnon Wood had been reminded of his predecessor's promise, and, as a result of representations to the Board, they had since advertised for an estate suitable for a State demonstration forest, but so far as was known, no estate had yet been acquired, and nothing further had been made public regarding the progress of the scheme.

In moving the adoption of the report, the Chairman said that during the last three years they had made less progress than he hoped, but they had made a good deal. Each year they had passed through a different phase, and he observed that with each new phase the progress became slower. First, the society had to choose a line for the development of sylviculture, and it fell to him to embody their ideas in a memorandum; and he desired to record the fact that their policy had not only been arrived at unanimously, but it had never varied. Since there was no one else to do it, they made an attempt themselves to tackle some of the difficulties of afforestation, and then a long and wearisome correspondence led to the appointment of a committee by the Secretary for Scotland to consider the policy they had laid before him. Then came the appointment of the Board of Agriculture, including a Department of Forestry, followed by the appointment of an Advisory Committee, and at this point his narrative ceased. He left it to Mr. Sutherland, whom they welcomed as the head of the Department for Forestry for Scotland, to take up the tale.

Mr. Sutherland stated that since the Board of Agriculture came into existence ten months ago, many matters other than forestry had demanded immediate attention, but in connection with forestry it had been decided to make a representation to the Development Commissioners of the urgent necessity for advisory and research officers for Scotland The Board also felt that progress might be made in the direction of a general survey of Scotland, showing the areas in which sylviculture was practicable, and a start in this direction had been made. Quite recently, too, the Board had been able to arrange for the testing of forest tree seeds for germination, and samples sent to the Secretary of the Board would be tested free of charge.

A discussion was afterwards initiated by Mr. Sydney Gammell, of Drumtochty, on the relationship of forestry to agriculture and other industries; in this a number of the members took part.

The financial statement showed that the funds of the society at December 31 last stood at £1,809 8s. 2d., and that there was a balance of income over expenditure for the year of £136 18s. 10d.

Captain Stirling, of Keir, was elected president for 1913, and Sir Andrew Agnew and Mr. Stewart Fothringham, of Murthly, were elected to the vacant vice-presidencies. Dr. Borthwick was elected honorary editor of the "Transactions," in succession to the late Colonel Bailey.

Chester Paxton Society.

Under the chairmanship of Mr. A. W. Armstrong, the opening meeting of the new session was held at the Grosvenor Museum, when Professor Robert Newstead delivered a most interesting lecture, entitled "Notes on the Flora of Nyassaland." The lecture was illustrated by splendid lantern slides from the professor's own photographs.

In his opening remarks the lecturer said he would deal with the flora very broadly, as, in consequence of it being the dry season of the year (which was Nature's resting season) during his three months' residence in Nyassaland (British Central Africa) there was not an over-abundance of plants. He thought, however, that before dealing with his subject proper, some remarks and illustrations on the journey, and its objects, the country and its inhabitants, would be acceptable to the audience. By the aid of maps shown on the screen, the lecturer described the geographical positions of the chief points of interest and explained the outward and homeward routes, pointing out the Rivers Zambesi and Shire, on the banks of which the camp of the expedition was pitched. Other slides showed the native means of travelling by rickshaw, porters carrying baggage, Sleeping Sickness camp on banks of River Shire, dining hut, the erection of the building by natives, women plastering walls, complete structure with verandah, and Dr. Davey with three of the native "boys," Newstead's Museum and Hospital, native gardener at work, and the two native servants, cook and table boy. The lecturer explained that there was an abundance of fresh fruit and vegetables, and he mentioned limes, tomatoes, and potatoes from the mountains. Other slides showed the cooking apparatus, etc.

Coming to the flora the lecturer said he would treat of the plants and trees under three divisions—First, the aquatic plants of the river; secondly, plants of the plain country; and, thirdly, those of the forest. The first picture showed the edge of the river covered thickly with a network of plants, termed "Sudd," among which were water calthrops and the cabbage plant. Other pictures showed Egyptian broad-leaved grass, acacias and palms, enormous ant-hills, which were common over all the country; sausage trees, so named on account of the resemblance of the fruit to sausages; Adenium multiflora, a plant without a leaf, but with a thick, fleshy succulent stem; an old ebony tree; "Women's Tongues," so called by the natives on account of the noise produced by the seeds when the wind blows. The lecturer pointed out where the pupa of the tse-tse fly was found, and explained that the situation was all low forest, and known to all Englishmen as "bush country"; later he showed where the pupa of the insect responsible for sleeping sickness was discovered. In concluding this portion of the lecture, Professor Newstead remarked that the flora of West Africa was much richer than that of Central Africa; but nevertheless, he had not seen anything abroad which would compare with our own native heather or gorse in flower. (Applause.) The remaining portion of the lecture was a rapid description of the avifauna of the country, as specimens were thrown upon the screen.

In the course of a few well-chosen remarks, Mr. Edward Porritt, Christleton Grange, a vice-president of the society, proposed a hearty vote of thanks to Professor Newstead. This was seconded by Mr. G. P. Miln, who said Cestrians were proud of the fact that Professor Newstead and the late Dr. Dutton (a native of the old city) had both been successful pioneers in scientific research work in the wilds of Africa and other places. This vote of thanks was put to the meeting and carried with acclamation.

Norwich Horticultural Society.

There was a goodly muster of local horticulturists at the annual meeting of this society, which was held in the Guildhall, Norwich, under the presidency of F. H. Barclay, Esq.

After the minutes of the last annual meeting had been read and other preliminaries disposed of, the Hon. Secretary (Mr. C. E. Pilling) presented the annual report, of which the following is an abstract: The society has had a successful year under the presidency of Major D. G. L'Estrange Astley, who has done so much during his year of office to increase the membership and also the welfare of the society by attending the shows and committee meetings, for which the committee wish to express their sincere thanks, and also to congratulate him on his success as an exhibitor at the Rose Show. The credit balance has been increased from £72 to £141 8s. 3d., and it will be remembered that last year, under the presidency of Mr. F. H. Barclay, the subscription list amounted to £219 18s., being a record, 89 new members having been obtained. That amount has been exceeded this year, the subscriptions now amounting to £233 11s. 6d., and 37 new members having been obtained, making a total of 497, as compared with 368 in 1910. This is very satisfactory, as it cannot be too forcibly impressed upon those interested in horticulture that the society can only be placed in a secure financial position by an increased membership. The committee much regret that Mr. Joseph Powley, the assistant secretary at the shows, has found it necessary to resign by reason of his advanced age. The Rose Show will be held on Wednesday and Thursday, June 25 and 26, a week earlier than usual, to avoid clashing with the great London show. Moreover, the expenses are not much increased by the second day. The appointment (on the suggestion of Mr. George Davison) of a sub-committee of experts to award the certificates of merit and medals of the Royal Horticultural Society has given much satisfaction.

The statement of accounts showed that the society had at the commencement of the year a balance of £72; subscriptions amounted to £233 11s. 6d.; receipts at Spring Show, £52 10s. 10d., Rose Show £142 13s. 11d., Chrysanthemum Show £260 5s., donations, etc., £60 2s. 6d., interest £10 6s. 4d., a total of £839 10s. 1d. After paying all expenses there remained a balance of £141 8s. 3d.

Mr. J. E. T. Pollard, in moving the adoption of the report and statement of accounts, said it was the most satisfactory report and statement that had been submitted for several years. Two records were made during the year. The first was the largest amount of subscriptions ever received. The

previous record was in the year 1834, so they had to go a very long way back to find anything like it. In that year there were 716 subscribers, and the amount received was only £201 16s. The other record was made on the third day of the Chrysanthemum Show, when over £60 was taken at the gate. Both of those records were very gratifying to the society, particularly the large increase in the amount of subscriptions.

The Bishop of Norwich was elected president for the year; Mr. E. G. Barclay was re-elected treasurer, and Mr. Pilling re-elected hon. secretary. The following retiring members of the committee were re-elected: Mr. H. H. Back, Rev. J. Fellowes, Mr. F. H. Barclay, Dr. Osbourne, Colonel Petre, Mr. W. Allan, and Mr. F. Hanson. Major Astley and Mr. Enderby were elected to fill the two vacancies on the committee.

The following show dates were announced: Spring Show, St. Andrew's Hall, April 24; Rose Show, June 25 and 26; and Chrysanthemum Show, November 20, 21, and 22.

Reading Gardeners' Association.

At the first regular meeting of the present session there was almost a record attendance of members, the president occupying the chair. The occasion was the visit of Mr. Thos. Stevenson, The Gardens, Woburn Place, Addlestone, the well-known sweet pea expert.

Mr. Stevenson prefaced his remarks by stating that he had no intention of going into the history of the sweet pea; the history of the flower as we know it did not extend back for a longer period than twenty years. His paper was entitled "The Cultivation of Sweet Peas," and to his subject he intended to adhere. The lecturer remarked it had been said that sweet peas could be grown on any soil, and with that statement he quite agreed. He had not yet seen soil that with careful and generous treatment would not produce, at any rate, peas of really decent quality. Mr. Stevenson then gave exhaustive advice as to the preparation of the ground and cultural details both with regard to autumn and spring sowing. He was an advocate of autumn sowing himself, but if it were not possible to sow the seeds before the middle of October, the better plan to adopt would be to defer the operation until the first week in February. Sweet peas would be found to come into flower more quickly on light soil, but they would bloom for a longer period on heavy land. Perhaps the best soil for sweet peas was something between a light and heavy soil, and which might be described as a fairly rich, porous loam with a free drainage. Mr. Stevenson gave at length his opinion of the dread "streak," with advice as to combating it.

The sterilisation of the soil, position for planting out, watering, feeding, use of special sweet pea manures, enemies and pests, growing under glass, and many other features were all thoroughly dealt with by Mr. Stevenson, who brought his remarks to a close by giving the names of twenty-four varieties "he would not like to be without."

In the discussion following the paper, Mr. Stevenson gave further evidence of his wide knowledge in the cultivation of the most popular of annual flowers.

Mr. W. T. Townsend, formerly head gardener at Sandhurst Lodge, Berks (late Sir William Farrer), and one of the oldest members and supporters of the association, was unanimously elected a life member of the society.

His son, Mr. F. Townsend, head gardener to the vice-president, staged a really superexcellent group of Primula obconica, which was unanimously awarded by the judges a Certificate for skill in cultivation. Mr. H. G. Cox (Messrs. Sutton and Sons) exhibited some wonderful autumn-grown vegetables, an example of the proper manner in which to preserve carrots, beet, etc., for winter use.

Several new members were elected.

ANSWERS TO CORRESPONDENTS.

HOLMES' MEMORIAL CHALLENGE CUPS.—J. A. M., London: Can you tell me the nominal value of one of the Holmes' Memorial Cups?—We believe the nominal value of a Holmes' Memorial Cup is £50.

SCABIOSA CAUCASICA.—W. B., Doncaster: I find some difficulty in producing perfect flowers of Scabiosa caucasica, and should therefore be glad if you would tell me whether the plant needs any special treatment.—Good garden soil and a sunny position will suit Scabiosa caucasica. The plant is in no sense faddy, and if your flowers come imperfect it may be that the soil is poor, that earwigs or other pests are troublesome, or that you have been unfortunate enough to obtain a very poor form of the species. We have a cypripedium that every year produces blooms in which the pouch, or lip, has a big indentation on one side, instead of a regular inflation, but, while the plant is kept as a curiosity, we do not condemn the species. Now and again a plant will develop some unpleasant character, and if good treatment will not bring it into proper form, then get rid of it and obtain plants from a stock that is known to be perfect.

CYPRIPEDIUM SEEDLING.—C. B. W., Lichfield: I enclose a bloom of cypripedium, and shall be glad if you will give me your opinion of it. The variety was raised in these gardens.—The seedling is evidently a form of C. Leeanum, a hybrid produced by crossing C. insigne with C. Spicerianum. For winter flowering this is a most useful orchid as it is free-flowering and easily grown. Your variety is a moderately good one, but has not such a broad dorsal sepal as is found in the best forms.

PELARGONIUMS FOR EXHIBITION.—G. B., Colwyn: Very many thanks for answering my previous questions. I now take advantage of your kind offer of further help. The pelargoniums in question are zonal varieties, and I require them for exhibition during July, chiefly at the beginning of the month. I have about fifty old plants in 6in. pots, and also a lot of cuttings which were rooted last August, and are now in 3in. pots. Plants in 6in. pots are, I believe, required for exhibition purposes. What I really want to know now is when to stop pinching the shoots and removing flower spikes, so as to secure a good display by the show time? If you can help me in this matter I shall be very greatly obliged.—You have good material to work with. Reduce the soil about the roots of the best of the old plants, and pot them into the smallest-sized pot that will conveniently hold them, and as soon as new roots have taken hold of the soil pot again, using rich, substantial soil. Encourage the younger plants by every possible means, remembering, however, that long sappy growths are not likely to be of much value. Pinching or stopping should cease six or seven weeks previous to the date of exhibition.

PLANTS DYING IN A CREOSOTED GREENHOUSE.—P. W., Norwood Park: I had a lean-to greenhouse built last September, measuring 19ft. in length, 8ft. wide, and 9ft. high, facing south. The whole of the house was painted inside and out with creosote. The plants and cuttings are dying: as soon as the young shoots appear, they wither up and die, as if burned. I should mention the fact that the plants seem to be much worse since we commenced heating. My gardener cannot assign any reason for the trouble, so we come to you for help.—The fumes from the creosote are responsible for the damage. We remember two instances in the south-east of London where begonias, pelargoniums, etc., planted out for the summer, were either killed off wholesale, or rendered unsightly by the fumes from creosoted wood paving laid down in front of the garden. It is most unfortunate that you had the woodwork creosoted instead of painted with good lead paint. How long it will be before the house is suitable for plant cultivation we cannot say, as there is so little experience to go upon. We know, in one instance, where the interior staging and the floor trellises were built with creosoted timber, the plants were killed, and it was not until all the woodwork so treated had been removed that the house was usable for plant cultivation. It occurs to us that, if the woodwork would take paint, then the house might be rendered useful in a few weeks if given two or three coats of first-class white paint; we simply offer this as a suggestion. If we can obtain any special information likely to prove useful in this matter we will communicate with you.

MALMAISON CARNATIONS.—C. H., Aberdare: Please tell me to whom we owe the Malmaison carnations, and where did this class originate?—How, when, or by whom the first Malmaison carnation originated we do not know, but it was evidently raised in France, and writers generally concede that Souvenir de la Malmaison, one of the earliest forms, was thus named in honour of Malmaison, the residence of the Empress Josephine, and where she had a garden. This is a red variety, and Old Blush, possibly the oldest, is blush coloured, and Princess of Wales, deep pink. For a long time these were the only Malmaison carnations in cultivation, but the late Mr. Martin R. Smith, of Hayes, turned his attention to these flowers, as well as to border carnations, and

NEWS FROM HEADQUARTERS.

A HALT AT THE PEA-PICKING MACHINES.

At the battery of pea-picking machines every visitor to Raynes Park comes to a halt.

Eighty-four of these wonderful machines, all driven by electric power, are humming musically from morning to night, feeding the deft fingers of the eighty-four operatives with an endless stream of peas, from which the bad are removed, while the good pass down a chute into the sack.

Nowhere else in England may these ingenious machines be seen. They are the only eighty-four in the country. Come and see them at work.

Each operative has absolute control of her machine. She may run it at varying speeds, and may stop it at any point in an instant. She may even regulate the flow of peas; she may have six in a row or sixty, or may have the travelling "platform" almost covered. The advantages of this facility of control are obvious: no two samples of peas are precisely alike; the machine must be run at lowest speed with a scantily covered platform for some crops of peas, whilst the more perfect crops may need but little picking, and can therefore be passed through quickly.

A very few moments spent watching this fascinating work profoundly impresses the visitor with the almost hypercritical care taken by James Carter and Co. to assure the perfection of their seeds. Surely, millions of the peas devoured by these machines with the yawning mouths and insatiable appetites might well be spared such scrutiny without jeopardising the reputation of the establishment; but so it is that a great reputation has been built and will be maintained at all costs.

The same wonderful machines are employed for picking beans, wheat, and oats; but just now they are busy with the peas, for a record demand is anticipated on account of the failure of the pea crops in many parts of the country.

raised a goodly number of handsome varieties, giving a wide range of colour. He even produced a yellow variety named Yeller Gal. At present there are between seventy and a hundred varieties of Malmaison carnations, but the old blush and pink sorts still retain their popularity.

QUALITY OF LOAM.—A. W., Notts: Is the turf, of which I send a sample, good material for potting purposes? I have some like it stacked for use in the coming season. What proportion of other materials, such as manure, leaf-soil, ashes from the garden heap, sand, etc., would you advise to use with it to make up a good general compost for potting, for tomatoes and for chrysanthemums? I do not use large quantities. Do you consider the turf has a fair amount of fibre in it?—The loam is of moderate quality, and would have been greatly improved had some manure been placed between the layers when the stack was made. It contains a moderate amount of fibre, but would hardly pass as first-class fibrous loam. For general potting, two parts of leaf-mould, one of old manure, and one of sand should be used to every five parts of loam, with the addition of a little wood ashes. For the tomatoes one part of ashes from burnt garden refuse to every four parts of loam would suffice, and the addition of a small proportion of road grit would improve matters. Tomatoes should be fed freely when they commence to fruit, not before. For chrysanthemums use five parts of loam, one of sand, one of ashes, and one of old manure, adding a pint of bone-meal to every bushel.

NAMES OF PLANTS.

C. A., Bournemouth.—1, Crocus chrysanthus; 2, C. Sieberi; 3, Iris reticulata Krelagei.

E. W., Liverpool.—1, Azalea amœna obtusa; 2, Cœlogyne Massangeana; 3, Oncidium (formerly Cyrtochilum) maculatum.

H. R. F., Andover.—1, Sparmannia africana; 2, Pelargonium denticulatum; 3, P. Lady Plymouth; 4, Rhododendron præcox.

R. H. H., Notts.—The azalea is A. amœna var. obtusa. The wood we do not recognise, but will endeavour to have it identified. Send us leaves and flowers in due course.

F. F. W., Launceston.—1, Prunus Pissardi; 2, Dendrobium Wardeanum—a very good form; 3, Cypripedium Spicerianum; 4, Dracæna Goldieana; 5, Nepenthes Mastersiana; 6, send when in flower.

OBITUARY.

MR. HENRY J. PEARSON.

We have received with regret information of the death of Mr. Henry J. Pearson, of Bramcote, Notts, which took place on Saturday, the 8th inst., at Assiut, Egypt, where he had gone for the benefit of his health. To the general body of horticulturists Mr. Pearson was best known as the head of the firm of Messrs. Foster and Pearson, horticultural builders and engineers, of Beeston, Notts, and will be remembered for the excellent work he did as a member of the Council of the Royal Horticultural Society, on which he had a seat for some years. To the world at large he was, perhaps, best known as an ornithologist of the highest eminence. For a long series of years Mr. Pearson devoted his leisure to the study of birds having their homes in northern regions, and paid numerous visits to the countries within the Arctic Circle in search of rare birds. In these expeditions he achieved so high a degree of success as to enable him to form one of the finest collections of Arctic birds and eggs in this country. Mr. Pearson was the author of two works on the birds of Northern Europe, which are much esteemed by ornithologists who give attention to the birds with which they deal.

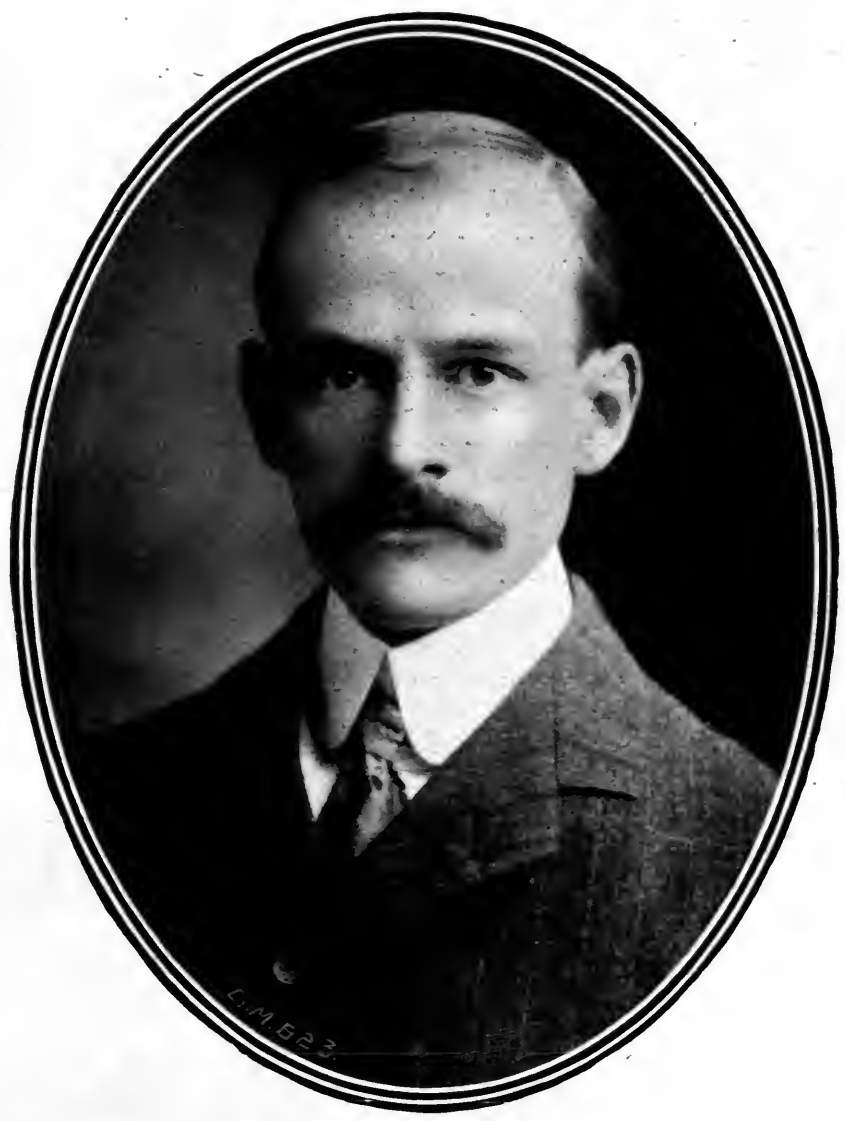
THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Dahlia Cult.

The conference on dahlias that was held in London the other evening, was of considerable importance as evidence of the quickening of interest in these distinct and attractive flowers that has followed the adoption by the National Dahlia Society of a policy possessing greater breadth and more vigour than the course of procedure which for so long was considered all sufficient. The attendance may not have been so large as the enthusiastic admirer of the dahlia could have wished, but it was more than sufficient to show that the interest in the flower is at the present time considerable, and it may be mentioned that every member of the conference was keenly interested in the several subjects that had been arranged for discussion. The programme was a good one, for not only were the several subjects in the hands of experts of the highest eminence, but they were so varied as to appeal more or less directly to all who were present. Both the exhibition and garden side of the dahlia received consideration, and, as will be seen by the report which appears on another page, the conference opened with a paper on exhibiting and judging the show and fancy varieties which for so long a period predominated at the autumn exhibitions. The newer types, and especially the cactus section, have proved such formidable rivals as to bring about a material decline in their popularity, and a considerable decrease in their cultivation. Yet they are still highly appreciated by many who grow dahlias for competitive purposes, and they invariably form a good feature at the shows where liberal provision is made for these flowers. It may, perhaps, be thought by some that, as these two sections no longer form the chief features of dahlia shows, the manner in which the blooms are staged and judged is a matter of secondary importance. So far from this being the case, it is desirable that close attention should be given to the manner in which they are presented to public notice, and to the procedure by which their relative merits are determined, for any falling away in the quality of the blooms in exhibition stands may at the present time do them irremediable damage. The charms of the blooms of the show and fancy dahlias consist in their perfection of form and the full development of their respective colours, and, as a consequence thereof, ill-shapen, rough, and indifferently-coloured blooms will repel rather than attract the visitors to the exhibitions, whether they are well acquainted with dahlias, or know but little about them. We may, indeed, expect them to suffer in precisely the same manner as the incurved chrysanthemum has suffered since it was displaced from its high estate by the Japanese type. The suggestion made by Mr. Wyatt, who is well known as one of the leading authorities on these flowers, that a code of judging should be prepared and published by the National Dahlia Society for the guidance of exhibitors and judges, has much to recommend it; and as the officers of the society stated in the course of the discussion that they were in full accord with Mr. Wyatt, there is justification for the belief that the preparation of a code will be taken in hand in due course. The papers by Mr. Cobb and Mr. Treseder, both of whom are resident in South Wales, dealt with the garden aspect of the dahlia from different points of view, and, as in the case of that read by Mr. Wyatt, were of a high order of merit. Mr. Treseder dealt with the future of the dahlia, and, in passing under review the several classes, we gathered that in his opinion this depended in a large degree upon the cultivation of varieties that have been proved to possess much value for decorative purposes, both in the garden and in the house. Mr. Cobb's paper was of special value from the fact that it contained numerous selections of garden dahlias, based on the results obtained in the remarkably beautiful and extensive dahlia garden at Duffryn, of which he has charge. This is by far the largest garden wholly devoted to dahlias in this country, and possibly any other, and its interest and attractions may be gathered from the fact that 2,000 plants are annually utilised in filling the beds and borders within its boundaries. This year Mr. Reginald Cory, the owner of Duffryn, who is a keen horticulturist, with a strong predilection for dahlias, will, with the co-operation of the Royal Horticultural Society and the National Dahlia Society, have a trial of garden dahlias on a most comprehensive scale, and under conditions that should ensure results of immense value to cultivators. A letter from Mr. Cory was read at the conference, inviting raisers and others, in a position to assist, to co-operate with him in making the trial as complete and conclusive as possible, and the response by the leading raisers and cultivators present was, we are pleased to state, most gratifying. Special reference was made by Mr. Cory in his letter to the importance of those who contribute new and other varieties for trial, sending the plants early enough for them to be shifted into pots having a diameter of six or more inches a month or so before the time arrives for transferring them to their quarters in the garden. At Duffryn strong plants are regarded as essential to the production of a really satisfactory display of flowers, and the 2,000 plants annually grown for beautifying the garden are well established in pots not less than six inches in diameter when they are consigned to their summer quarters. As the result of this practice, the garden is gay with flowers from the early part of July until the growth is cut down by the frost, instead of the beds being for the most part masses of greenery until the month of August is well advanced. The



MR. PERCY CRAGG.

practice which has been adopted with so much success at Duffryn, has been recommended in these pages on more than one occasion, and adopted by many of our readers. The changes in public taste have had their influence upon the fortunes of the dahlia, and the mistake of selecting exhibition varieties for the production of colour effects in the garden have injuriously affected them; but the extension of dahlia culture has probably been most seriously hindered by the practice of treating the plants in the same way as zonal pelargoniums and some other tender bedders are usually treated. Plants that are kept in pots not exceeding three inches in diameter, from the time they are removed from the cutting pots until they are planted out, seldom attain to so high a state of development as those which have the advantage of a shift into pots with a diameter of six inches, and of a substantial compost, and they are a month or so later in coming into bloom, the latter being a point of some importance, having regard to the shortness of the period over which the English summer extends. Not unfrequently an objection is raised to the adoption of the practice here referred to because of the size to which the plants attain when grown under generous conditions during preparatory stage, and the difficulty of providing room for them under glass. We appreciate the difficulty that is frequently experienced during the spring months in providing the accommodation required for the stocks of tender bedders, but great as it may be, in many gardens it does not sustain the objection referred to. One dozen strong plants is worth six dozen weakly ones, and therefore the only satisfactory course is to estimate the space that will be available, and grow as many plants as it will accommodate when they are well developed. Another point of importance to which special reference was made in the course of the discussion was the necessity for selecting varieties adapted to the purpose for which they are specially required. This should be obvious, but evidently it is not so to all, and we, therefore, reiterate the advice previously given in these pages that those who purpose exhibiting should grow varieties producing blooms of the highest possible quality, and in selecting varieties for garden decoration, the habit of the plant and freedom of flowering should have first consideration.

Mr. Percy A. Cragg, of Messrs. Cragg, Harrison, and Cragg, Merivale Nurseries, Heston, near Hounslow, is, even among advanced and successful market growers, considered to be one of the smartest men in the profession. Always studious and a great seeker after truth among those principles that underlie practice, Mr. Cragg has most happily combined scientific knowledge with practical work of great extent. Soil composition, the uses and values of manures, soil sterilisation, and rigid selection of stock plants for propagation, are all matters which Mr. Cragg has studied with advantage to his business. He literally grows his own soil for the immense number of chrysanthemums he cultivates, and in the preparation of the soil for potting he aims at skilful mixing that will obviate the need of feeding. Mr. Cragg says he started gardening at the age of seven, with a penny packet of seeds and two panes of glass. Now he controls several acres of glass houses, and is in the very front rank of cultivators of chrysanthemums, tomatoes, mushrooms, ferns, miniature cacti, smilax, aralias, and ornamental asparagus. For three years Mr. Cragg was with Mr. Edmund Rockford at Mill Lane, and for one year at the new nursery at Stanstead. After that he spent a year at Mr. Beckwith's nursery, and a summer with Mr. J. Sweet at Whetstone. He started at Heston in 1896. Mr. Cragg is widely read, a most interesting conversationalist, and he finds recreation in hockey and tennis. In the National Chrysanthemum Society he has done excellent work as a member of the General and Floral Committees; and he has contributed excellent papers to the various conferences, freely telling of successes achieved and errors to be avoided.

The Abnormal Winter Season. The blossoming of many shrubs and plants before their usual season has been recorded in these pages, "but," writes Mr. George Bunyard, "the most remarkable thing I have noted this winter is that April broccoli were here and there heading in at Christmas, in our nurseries at Maidstone. In a long lifetime I have never observed such precocity before."

Presentation to Mr. W. H. Massie.—A few days ago Mr. David King, the new president of the Scottish Horticultural Association, entertained the Council to dinner at the Royal British Hotel, Edinburgh. There were over thirty present, and a very pleasant evening was spent. Mr. King presented Mr. W. H. Massie with a handsome solid silver rose bowl, subscribed for by the Council as a token of appreciation of Mr. Massie's services as president during 1911 and 1912.

Exhibition of Garden Dahlias.—We have received the following communication from the Royal Horticultural Society relating to the exhibition of garden dahlias, to be held September 23: The object of this competition is not so much to attract the finest cut blooms as seen on the show stand, for such flowers may, when growing on the plant, be almost invisible, and therefore are no contribution to the decoration of the garden, whatever they may be for cutting. The object is to discover the most decorative garden dahlias, that is, those varieties which add most to the beauty of the garden, and, as is well known, not a few of the most glorious dahlia flowers add nothing to the aspect of the garden, as they are hidden beneath the foliage. They may be excellent to grow in the kitchen garden to cut for house decoration, but they are useless for the ornamentation of the pleasure garden. Class A; Amateurs: Decorative garden dahlias. Any section except show dahlias, which are excluded. 12ft. run of 3ft. tabling, not exceeding 8ft. in height. First prize, silver cup, to which will be added the Veitch Memorial Medal. The Council will make other awards according to merit. Class B; Open: Decorative garden dahlias. Any section except show dahlias, which are excluded. 25ft. run of 3ft. tabling, not exceeding 8ft. in height. First prize, 70 guinea challenge cup, presented to the R.H.S. by Reginald Cory, Esq. The Council will make other awards according to merit. The winner will hold the cup for one year, subject to a sufficient insurance against loss, and to a guarantee to return it in good condition, or, failing this, to refund to the R.H.S. the sum of 75 guineas. On the return of the cup the Council will present the holder with a small cup of similar design. The same exhibitor may only win the cup once in three years, but, should the winner of the previous year be again considered first, the Council will bestow a special award. The decision of the Council is final, and the cup may be altogether withheld at their discretion. The Council will not award this high distinction unless satisfied and assured that the exhibit is, in the main, due to the work and capability of the exhibitor or his employees. On this point the Council may consult any expert not eligible to win the cup.

Sunshine and Rain at Glasgow in January.—According to observations made at the Glasgow Observatory in January, the mean daily temperature was below the normal on nineteen days, but, owing to the extreme mildness of the first ten days of the month, the mean temperature for the whole month, 38.6, was only a tenth of a degree below the average for January in the last forty-five years. Ground frost was registered on fourteen nights, the lowest record being 17.9 degrees, or 14 degrees of frost. Snow fell on five days, and on the 13th was lying nearly three inches deep. The total rainfall for the month, 3.44 inches, is 0.23 inch below the average for January since 1868. The number of days with rain was nineteen, or one day below the average. Bright sunshine was recorded on four days, and the total number of hours for the whole month was seven. This is the lowest record of sunshine for January in the last thirty-three years.

Proposed Hooker Memorial Lecture.—Presiding at the fortnightly meeting of the Linnean Society, Professor E. B. Poulton, F.R.S., stated that the Council of the Linnean Society have had under consideration the application of the bequest of £100 left to the society by the late Sir Joseph Hooker. They feel that the Fellows of the society would not desire this legacy to be applied to the ordinary purposes of the society, but that they would wish it to be used for some memorial of the illustrious donor in connection with the society. Such a memorial would be peculiarly appropriate, since the late Sir Joseph Hooker was for nearly seventy years one of the strongest supporters of the society, taking the keenest interest in its work. The Council have agreed that the most suitable memorial would be an adequately endowed Sir Joseph Hooker Lecture, to be delivered every second, third, or fourth year, and to be published by the society. They propose that the lecture be on some subject especially associated with the name of Sir Joseph Hooker, and that the lecturer be appointed by the Council, not necessarily from among the Fellows of the society. They suggest that the generous bequest of £100 should form the nucleus of a fund to be raised for the purpose of carrying this proposal into effect. The Council are gratified to know that their proposal meets with the warm approval of Lady Hooker. The Council consider that a total sum of not less than £600 should be obtained and appeal to the Fellows of the Linnean Society and others to contribute.

The Ghent Quinquennial.—The opening of the Ghent International exhibition will coincide with the famous Ghent Floralies, or Quinquennial, that periodically brings many thousands of visitors to the old capital of the Courts of Flanders. This exhibition will be held in the great palace of glass situated in the centre of the Universal Exhibition Park, and the area available for the display of the plants invited by the schedule will be about 24,000 square yards, and the structures provided for orchids and other tropical plants have an area of about 6,000 square yards. It is intended that the palace of azaleas shall form a special feature. The jury will comprise some 300 members selected from the leading horticulturists in all parts of the world. The Gardeners' Company, of which Mr. G. R. Blades is Master, are sending a deputation to Ghent,

which will visit Bruges and other places in Belgium that are celebrated for horticulture.

Richmond Horticultural Society.—Mr. George Cave, K.C., M.P., has been appointed chairman of the committee of the Richmond Horticultural Society, in succession to Sir Thomas Skewes-Cox.

Crocuses at Hampton Court. The gardens of Hampton Court Palace are now gay with the flowers of the crocuses that bloom in spring, and the thousands of bloom that bespangle the grass contiguous to the lime tree avenue produce a charming effect. Purple, white, and yellow varieties are all well represented, and blooming about a month in advance of the period at which their flowers usually contribute to the charm of the garden.

Mr. A. R. Blanchard, of Stone Easton, was successful in winning the silver challenge cup presented by Mr. J. Thatcher, the president of the Midsomer Norton Gardeners' Association, at the commencement of the season of 1911-12, to be awarded to the exhibitor obtaining the highest number of marks at the monthly meeting. Mr. Blanchard obtained 50 points, and the cup was handed to him by the donor at the society's meeting for the current month.

Abies bracteata at Bury Hill.—From Mr. Graysmark, who has charge of the gardens of Bury Hill, Dorking, the residence of Robert Barclay, Esq., we have received cone-bearing specimens of the interesting and handsome silver fir known as Abies bracteata. The specific name of the species is derived from the great length of the light brown bracts, which give to the cone a distinct and attractive appearance. This species is a native of Santa Lucia, South California, and was discovered by David Douglas during his mission to that region in 1830-32 on behalf of the Royal Horticultural Society. He was, however, unable to collect seeds. In 1846 Theodore Hartweg, who also was employed by the Royal Horticultural Society, visited South California for the purpose of obtaining seeds of this and other coniferous trees, but he found the cones had been so seriously damaged by frost that they had not attained full development, and was unable to collect seeds. Visiting South California in 1852-3, in the interests of Messrs. James Veitch and Sons, William Lobb was more successful, and succeeded, with some difficulty, in collecting a supply of seeds. These reached England in 1853, and, as mentioned in Veitch's "Manual of Coniferæ," all the oldest trees now growing in Europe originated from them. During the next thirty years, according to this work, the attempts to obtain further supplies of seed failed, but since then small quantities have been collected. Although distinct in character, and very beautiful when grown under the conditions favourable to its full development, this fine silver fir has not been largely planted, owing to it not being quite hardy in the less-favoured districts of the United Kingdom, and to the supposition that it is more tender than is really the case. It is quite hardy in the south and west of England, and in several parts of Ireland and Scotland, and there is a moderate number of finely-developed trees ranging between forty and sixty feet in height, one of these being in the gardens of Orton Hall, Peterborough, although the district in which these gardens are situated is not very favourable to arborescent vegetation other than that possessing a hardy constitution. The trees are slow in reaching the cone-bearing stage, and the specimen in the gardens of Bury Hill is now bearing cones for the first time.

CROCUS KATHLEEN PARLOW.

Flowers white, with faint line of purple along the centre of each inner segment. A.M., R.H.S., February 18. Messrs. Cartwright and Goodwin, Kidderminster.

GARDEN DAHLIAS.

The following is the text of the paper read by Mr. A. J. Cobb, of Duffryn Gardens, at the conference held by the National Dahlia Society on the 14th inst.:

I think I cannot do better than give at the commencement of my paper what is, in my opinion, the definition of a garden dahlia. I take it to be one which combines freedom of flowering with the flowers poised on long stiff stems, well above the foliage. Providing these conditions are fulfilled, they may be drawn from any of the now numerous sections, and, thanks to the enterprise of many raisers, both at home and abroad, we now have a wide range both in type and varieties to choose from. I hope the many lovers of the cactus section will forgive me when I say that their favourites do not meet these requirements. I should not like to see the decline of the beautiful cactus; they are exquisite both in form and colour, but I have yet to see, with about two or three exceptions, any cactus variety that can compare with many others I will name for garden decoration.

To exemplify their great drawback I may mention that it was my privilege to see last season a fairly large collection grown principally for exhibition, and what did I see? Not a floral display, but a wonderful sight of Nature's setting colour, green. The flowers must have been playing hide and seek among the foliage. No; they are not typical garden flowers, but purely flowers for the florist and exhibitor; but the mention of the last word, what does it imply?

Probably, one may say that for every one who exhibits, be it dahlias, roses, sweet peas, or what not, there are fifty who grow for the pleasure of seeing them in the garden. The exceptions I have in my mind are Miss Willmott and Penguin; the former is quite an acquisition to the garden, having flowers of a clear orange, freely produced, and most gracefully balanced, while the latter throws its pale gold flowers well above the foliage. We tried many of these so-called decorative cactus at Duffryn, but they are far from satisfactory. We shall retain them, but in a place quite apart from other types.

To raisers, however, I would appeal not to relax their efforts, for if they can succeed in producing some rich colours of the Miss Willmott type of growth, they will have earned the thanks of many garden enthusiasts.

The old show and fancy section must also come under the ban of unsuitability; some few varieties might pass muster, but as a whole they are not advisable. Nevertheless, they are fine old flowers, and a few will be grown with the cactus.

We will turn to the other side of the picture.

The pæony-flowered dahlia, the one-time much-abused pæony. It is now, I am glad to say, fast gaining friends. Why it has taken so long passes my comprehension, for anything more beautiful than a bold display of selected varieties I cannot imagine.

I think that those prejudiced against them can never have seen a good collection growing. Another thing, it was somewhat of a surprise to find how few people have really seen them in the garden. People of all classes, gardeners, nurserymen's travellers, and the general public, all expressing their astonishment at the wonderful sight produced from our collection of over 100 varieties of this class.

The flowers have been termed garish; certainly there are bright colours, but what is the aim in a flower garden but brightness?

Some of the more showy sorts are represented in Holman Hunt, Geisha, Liberty, Duke Henry, and Countess of Lonsdale—but are they not beautiful? Again, are there not colours and tints of extreme softness and delicacy? In fact, I question if any flower known to horticulture gives such a range. Some of the more tall and robust growers may be too powerful for small gardens, which is, I believe, an objection sometimes levelled against them; but there are plenty of good varieties of medium height and vigour. A little later I will give a dozen suitable for this purpose.

As to a selection of the best sorts generally, the numbers are so large and constantly being added to, that it is very difficult indeed to advise. I wonder if something could be done in the way of classifying the pæony section. It is not an easy matter, I admit, but say anyone has decided to grow a hundred plants or upwards, it is almost a hopeless task wading through the descriptive lists, and still more difficult to plant so that the best possible effect may be obtained, and no glaring colour mistakes made. If the society could issue such a list, I think it would be of much assistance, or failing that, I would suggest that the trade who specialise in this section would, in addition to their catalogued alphabetical list, divide up the colours as far as possible. There would not be much difficulty with the self colours, but the shading, suffusing, tinting, splashing, and streaking, described in others, does, I admit, at first sight, appear somewhat of a Chinese puzzle. To solve that problem some particular variety may be taken as a standard, and group others similar around it. They would, of course, vary a little, but that would not matter if the colours blended.

This is the principle we are working on at Duffryn, and I give it feeling, however, that it is of necessity far from complete, as it only comprises selections from those we grew last year. I know there are many others highly spoken of, notably Tettenhall Scarlet, Mrs. Digby Burdett, Cæsar, Mrs. J. B. Riding, etc., which I am anxiously looking forward to seeing.

Commencing with the whites, we placed ours in this order—Mrs. T. A. Weston, Mrs. T. G. Baker, Lady Paget, and Connie Humphreys. Strangely enough, the first-named is not listed as pure white, but if we have the true variety, it came pure white with us, and was a lovely flower. Connie Humphreys has a pale yellow centre, but is too good to leave out. Yellow King Leopold, Codsall Gem, and Hon. Mrs. W. Forbes, all these are well known, and I should place King Leopold among the best half-dozen in the whole pæony section.

Pink.—Countess Grey, Harrismith, Mrs. W. E. Whineray, and Queen Emma. Many of the pinks have a faint suffusion of yellow.

Deep Rose.—Ladysmith.

Scarlet.—Liberty and Lullingstone. These are fine, but there may be others unknown to me.

Crimson.—Holman Hunt, Duke Henry, Peru, Antagonist, and Leveller. In this section we have a grand assortment, but Holman Hunt stands out first as faultless.

Apricot Suffused Rose.—This commences a class more difficult to deal with; there are Lady Norman, Mafeking, Merveille, and Bloemfontein, but I take Lady Norman as an ideal plant and flower, and the others are closely allied to it in colour.

Scarlet and Gold.—Geisha, Lady Saville, W. H. Morter, Faust. This is a telling class, with Geisha a grand flower.

Carmine Rose.—Countess of Lonsdale, Mrs. E. G. Wythes, and Careless. These comprise three of the finest.

Bright Rose, shaded Yellow and White.—Mrs. Geoffrey le M. Mander, Mrs. R. Cooke, Viscountess Wolverhampton, The Tatler. This is a class around which endless varieties may be grouped.

Yellowish Salmon, Apricot, and Buff.—Lady Cleeve, Mrs. A. Mackellar, Romolo Piazzani, Bronze Gem, Col. Cody, and Sunset. A lovely group. There are probably more varieties on these shades than any other.

Very Pale Pink, suffused Rose.—Mrs. Kerr, Fanny, Dr. Van Gorkom, and Miss Watson. This is a delicate and pretty class, and give us a good intermediary between white and pink.

Large as it is there are many extremely beautiful varieties left out of this list. I will end my remarks on the section by giving a good dozen for medium or small gardens: Connie Humphreys, Bloemfontein, Warrior, Codsall Gem, W. H. Morter, Col. Cody, Sunset, The Tatler, Mrs. Kerr, Countess Grey, Marginata, and Lullingstone.

We will now briefly consider the claims of the "Decorative Section."

It will not be necessary for me to dwell very long on these, for I feel it will be like treading a beaten track. I do not know when Souv. de Gustave Douzon was introduced, but one naturally turns to this good old variety as the champion of the section. I well remember the first time I saw it, and as it was quite the largest dahlia I had seen, it left an impression on my mind. The way it holds its huge scarlet blooms up is very fine, and a mass of these make a display not readily forgotten. The Mahdi attracted much attention with us, the blooms are very large, and the colour, yellow ground with carmine markings, and the habit good. We were particularly pleased with several of the medium size type, and were I asked to name my favourite it would unhesitatingly be Loveliness. Whoever named it had no difficulty, as the flowers suggested its name. The blooms are perfectly formed and of a lovely pink colour.

A variety which appealed strongly to many owing to its unique tubular-shaped petals was Grand Duke Alexis. Some others which pleased us were Le Colosse, Yellow Colosse, Princess Juliana, Delice, Jeanne Charmet, Queen Mary, Mons. Capron, and Source de Feu. Among the smaller decoratives I would particularly mention Glare of the Garden, and its orange form; both are intensely free bloomers and gems of any garden, growing from 2½ft. to 3ft. tall. Another we cannot leave out is Sea Shell, a variety growing about 4ft. high, and smothered with its delicate blooms.

"The Collarettes" must now come under review.

This is the type par excellence for everybody. I say this because they are ideal for small gardens, and equally so for large. I think all dahlias show to better advantage if a garden large or small can be set apart for them, but where this is impossible the collarettes are not too large for beds or herbaceous borders, where, perhaps, some varieties of the pæony and giant decoratives would dwarf the other subjects. Although different sorts vary in habit, all that were grown here comply with my idea of a garden dahlia, and on the assumption that they are all good, one may add the newer introductions noted at last season's shows with every confidence.

Of the two types, round flowered and star-like, I prefer the former, though the latter are very dainty. A selection of the best varieties again represents a problem. Some of our best last year were Holyrood, Maurice Rivoire, Exposition de Lyons, Souv. de Bernardeau, Grand Papa Charmet, Diomede, and Souv. de Chabanne, of the round flowered type, and Queen Mary, Diadem, Leitstern, and Goldstern of the star-like. All these are far too good to discard for any of the newer ones. Souv. de Chabanne has the drawback of being about the latest to come into bloom—the second week in August with us, but has probably the longest and stiffest flower stems of all, plenty being quite two feet, and a splendid yellow bloom. The stems of Souv. de Bernardeau and Diomede are a little longer than most, but all are good. The latter we found last fully a fortnight in water. In addition to those named, I noted the following at last year's shows as being very fine: Antwerpia, Buckingham, Balmoral, Hon. Vicary Gibbs, Prince John, Princess Louise, Prince Charlie, Frogmore, The Czar, Albert Maumene, Ideal, Madame Gygax, and Queen Bess. When we remember that this section has only been before the English public about three years, I think the advance made during that time is sufficient proof that the future looks very bright, and in a few years I should not be surprised if it is a rarity to find a garden without them. I don't know whether they have reached hall mark, but I cannot see where they can be much improved. In any case raisers must see to it that the habit is not sacrificed or away goes their value for the garden.

(To be continued.)

CYPRIPEDIUM IDINA.

The great idea of the cypripedium raiser of to-day is to obtain a flower with an enormous dorsal sepal. His idea finds expression readily, but often, alas! he secures what he set out to get, but with it comes a want of proportion in the flower as a whole, while the question of colouring seems to be worthy of small consideration. In Cypripedium Idina, however, a finely and well-proportioned flower has been produced, one that appeals to the florist, and does not offend the lover of species or primary hybrids. The large Cypripedium insigne Harefield Hall is one parent of this newcomer, and C. Countess of Carnarvon is the second parent. The illustration herewith shows how strong is the influence of the first-named. The rounded white dorsal sepal, with its pale green base and centre, is a fine feature that is rendered the more attractive by the numerous light mauve-purple spots. In the petals and broad labellum the colouring is green, shaded with brown, each part being finely burnished.

It will be noticed, too, that the ventral sepal is considerably developed, a characteristic noticeable in a number of recent productions. Whether the time will come when we shall have cypripediums with each sepal fully developed and similarly coloured, each petal greatly broadened, and the labellum almost suppressed, is an interesting surmise. Anyhow, we must wait and see, but the tendencies are in these directions, except that the pouched labellum shows little signs of diminution.

Cypripedium Idina, exhibited by Messrs. James Veitch and Sons, Chelsea, at the Royal Horticultural Hall, Westminster, on Tuesday, December 17, last, gained an Award of Merit on that occasion.

EARLY DAHLIAS.

An accusation commonly laid against the dahlia is that its flowering season is so short, for it is generally at its best in the middle of September, and a single night's frost in early October may carry off the entire plants. Under such circumstances the dahlia's life is a very brief one. I often think the tiny little plants one sees planted in early June must have a great struggle to flower even by September, yet it is wonderful what they will do in such a short period.

To ensure a long season of flowering the cultivator has two cardinal points to bear in mind. In the first case he will find that plants grown from pot roots flower earlier than those from rooted cuttings, and where the plants are required for beds or garden effect they will be the best. Pot roots, so-called, are small tubers that have been grown in their small pots all the previous season. In the autumn they are turned out of their pots for storage. This is the type of plant that is always exported, but it will be found that for early-flowering purposes they are unsurpassed. They should be purchased at the present time, and started in a warm greenhouse, and in a week or two the buds will be pushing at the base of the old stem. Many will start with two or three buds, and the grower must decide how many of these shoots he will allow to develop. In the case of decorative cactus dahlias only two buds should be allowed to break into growth, and the same remark applies equally to the decorative sections, while the singles, pompons, and collarettes may be allowed to grow quite naturally.

It is a mistake to hurry the plants in too much heat. A gradual development is required. If the plants are grown sturdily they should be ready to place in cold frames early in April, where they can be protected from frost, but air should be admitted on all favourable occasions.

The second cardinal point is, perhaps, if anything, more important than the first. It is never to allow the plants to become root-bound from the time they are started until planted out for the summer. A plant that becomes pot-bound is checked to such an extent that it is a slow process persuading it to grow away freely again, for as soon as the roots are cramped for room the stems quickly harden, which is certainly all against the well-being of the plant. The dahlia has to grow so much in a short space of time that, if it is checked, either by being root-bound or through lack of moisture at the roots, it rarely becomes a success.

Briefly then, the grower who starts his pot tubers at the latter end of February must see that they are potted as they require it, right up to the time they are planted out, and, I might add, if they are grown chiefly in cold frames this is not such a heavy task as it appears on paper. Keep them as sturdy as possible, but guard against frost, then, by the end of May or beginning of June, one has plants to be proud of, that make a show at once, that will withstand the onslaught of slugs, and give satisfaction later by early and free flowering.

As most flower lovers are aware, the dahlia as a decorative garden plant will be very much to the fore during the coming summer and autumn, not only in our public parks and gardens, but at exhibitions, where an effort will be made to popularise the dahlia for this purpose, not to the detriment of the exhibition varieties, but to draw attenton to the dahlia's unrivalled beauty as an autumn-flowering subject.

J. B. RIDING.

CROTONS.

There are now so many desirable flowering plants that crotons, or codiæums, are probably less generally grown than formerly; however, they are very desirable fine foliage plants, and should find a place in all gardens where it is possible to grow them. Plants may now be selected and carefully potted, using a compost of two parts loam to one of peat, with a fair addition of sand. The remainder may be used for propagation, which may be effected either by means of cuttings inserted singly in small pots and plunged in a propagating case where a good bottom heat is maintained, or by means of ringing, or notching, under a joint at which it is desired to form roots, and binding round firmly a good handful of moss containing a very sandy compost. When this method, which is probably the better one, is adopted, the moss must be kept constantly moist by means of the syringe until roots are showing through, then the top may be entirely removed from the plant and potted, placing it in a close frame in the stove until established. Crotons delight in plenty of heat, moisture, and full sunshine.

EXPRESS GRAPE CULTURE IN POTS.

The grape vine cannot be forced very early for several years in succession without showing signs of distress, both in vigour and fertility, and for this reason the method of fruiting it in pots has advantages. The gains are chiefly derived from the fact that it is comparatively easy to keep up a regular supply of very early grapes, by annually forcing fresh sets of pot vines, than to do so by periodically preparing permanently planted vines for the purpose. For producing fresh, ripe fruit in March, April, or May, it is, therefore, advisable to grow pot vines, and the best varieties for the purpose are Black Hamburgh and Foster's Seedling, the supply to follow being from permanently-planted vines of similar varieties, and Madresfield Court, Buckland Sweetwater, etc., their roots being confined to inside borders.

For many years, while in charge of the gardens at Cardiff Castle, the late Mr. Pettigrew was a very successful grower of vines in pots, and Mr. Farmer, the present chief of the Castle Gardens, is an equally skilful cultivator. Many growers make use of "cut backs" for fruiting—i.e., they grow canes from "eyes" one season, and after they are thoroughly matured cut them down to a basal bud, from which they secure a stronger rod. By this means it takes two years to produce fruiting plants. At Cardiff, however, this method is considered, and proved to be, a waste of time and labour, and there canes are grown from eyes in one season, that each yield the following year from twelve to sixteen bunches of excellent grapes, averaging from 1½lb. to 2lb. each. It has occurred to me that some brief notes on the methods adopted may be interesting.

The first step taken is to prepare eyes from thoroughly matured wood, and plant them singly in three-inch pots in the ordinary manner, fine loam, mixed with leaf-soil and silver sand, being used as compost. Early in January the pots are plunged in a bottom heat of about 70 deg., the night temperature of the house being 60 deg., and that for the day 70 deg. from fire heat, with the usual rises from sun heat. As soon as free root action has taken place, and about four inches of top growth made, the plants are shifted into 5in. pots, carefully staked, and placed well up to the glass upon a bed. With careful attention to ventilating, watering, syringing, etc., the plants make satisfactory progress, and a shift into 8in. pots is given once it is found to be necessary, at which time larger stakes are used as supports. The next and final potting into 12in. pots is made as soon as the plants have again well filled the soil with roots, and in attending to it special care is taken to secure efficient drainage, and properly firm the compost. As this work proceeds the plants are arranged near the glass upon a front stage, and trained to a roof trellis. Side growths are kept regularly stopped at one leaf, and the leading ones carefully secured, and allowed to extend until the vines are 13ft. in length before they are stopped.

Throughout the whole season of growth no pains are spared to ultimately secure strong, short-jointed, and thoroughly matured rods, and that this satisfactory state of things has for many years past been secured, has been evidenced by the splendid crops yearly produced. Early in September the canes are sufficiently ripened to be placed outdoors, and here a sunny, sheltered position is found for them where they have their rods secured horizontally near to the ground to stakes. As soon as their leaves fall they are pruned, the rods being left to 10ft. or 12ft. in length, according to their strength.

A long span-roofed house is devoted to the vines during their fruiting year, in which the pots are plunged (for the purpose of the more easily keeping the roots moist) in narrow borders, placed near the glass on each side, the rods being trained near the roof upon trellises. During both the growing and fruiting seasons Mr. Farmer is particularly careful that his vines are not permitted to suffer from lack of proper nourishment; indeed, the results obtained would certainly not be forthcoming if any cultural neglect took place. The manures employed are clarified liquids from the cow byre, and Clay's and Thomson's, and for the convenience of applying them during the fruiting year, bands of turf are placed round the rims of the pots.

The ingredients of the compost used for potting purposes were not ascertained, but it may be remarked that a mistake in this respect can scarcely be made if one formed of three parts of sound fibrous loam, and one part of crushed mortar rubble, and flaky leaf-soil, or pulverised horse manure, in equal parts, with a dash each of bone-meal and wood ashes added, is made use of. This for the large pots particularly should be used in a reasonably rough condition. The varieties thus fruited at Cardiff are Black Hamburgh, Foster's Seedling, Madresfield Court, Appley Towers, Black Morocco, Alnwick Seedling, Alicante, and the best-flavoured, perhaps, of all grapes, Grizzly Frontignan.

T. COOMBER.

The Hendre Gardens.

SWEET PEA NOTES.

The mild, sunless winter has not been an ideal one for many subjects cultivated under glass, and amongst other things that have appeared to suffer are the autumn-sown sweet peas. At the time of writing, February 6, the plants are not quite in as hardy a condition as one would like to see them, and there is not quite the same disposition for them to break away at the base as I have noticed in some seasons.

There is, however, plenty of time for a week or two of severe frost before the end of the month, and such weather would probably have a steadying effect upon the plants, making the leading growth somewhat harder, and thus induce the plant to give good strong shoots from the base; these latter we consider quite necessary, not only for the production of good blooms in due time, but to secure the necessary number of shoots. If the plants do not break from the base by the end of the month it might be advisable to take out the extreme point of the leading shoot, though this is a practice which I am not in favour of in a general way, but there are exceptions to every rule.

I have so often given advice in respect to the treatment of the plants that it seems unnecessary to repeat it, but the importance of giving the young sweet peas all the light and air possible is so great that I feel I must emphasise the point even at the risk of being thought superfluous.

Plants raised from seed sown in the open ground, notwithstanding the wet, are looking well; in fact, some of the big growers assure me their stock never looked better, and for the sake of these latter I hope we may not have sufficient frost to injure the plants. Where the soil is of a very light nature a little drawn up with a hoe on each side of the plants will do much to protect them in the event of a severe frost, and though this would not prevent the tops being frozen, it would possibly preserve the roots and part of the stem, which would soon break into growth again under more favourable conditions.

On heavier soils the chances of bringing them through the winter successfully are not so great, but, providing they have a good root hold, and the freezing is not too severe, they will come away again, and certainly they should not be ploughed or dug in until they have had a chance of making a fresh start.

The germination of seeds in the autumn was not so good as I have found it in some seasons, and not nearly so good as in 1911. In many instances it has been necessary to sow again to make good the deficiencies, so those growers who rely on spring sowing would be well advised to sow rather more than they require of the smaller-seeded varieties, and so save themselves considerable anxiety later on. The advisability of chipping some of the harder and black-seeded varieties was rather forcibly brought to my notice a short time ago. Thinking the seed would not be quite so ripe this season owing to the wet late summer and autumn, and being pressed for time, seeds of several varieties that I usually made a practice of chipping were sown without it. Owing to structural alterations to frames, etc., the plants were not thoroughly examined for over two months after sowing, and it was found that some five or six varieties had not germinated 5 per cent. The seeds were searched for, and found as hard as at the time of sowing, although the soil was kept fairly moist (I should say these were 1911 seeds). On chipping these seeds, and placing the pots in a little warmth, most of them germinated under a week, and practically every one germinated in about a fortnight.

Peas for flowering under glass should now be ready for their flowering pots, or for planting out in the houses if they are to be flowered in this way, and where there is plenty of head room there is not the slightest doubt as to this being far and away the best system, as the extra quality in the flowers, and the extra length of time, they will give good long-stemmed blooms, must make them much more remunerative. Well cultivated and manured soil is just as necessary under glass as out of doors, and before planting the soil should be made moderately firm to ensure a very steady growth at the outset, as under glass the ground does not get beaten down again by the weather, hence the necessity for treading it a little.

A good watering in should be given immediately after planting if the soil is at all dry, but after this very little more water will be required for some time, though as the days grow longer and brighter, a damping overhead will greatly benefit them; but a fairly hardy, cool treatment is absolutely essential in the early stages if the plants are to be flowered before they attain an unreasonable height.

THOMAS STEVENSON.

THE ROYAL NURSERIES, WALTHAM CROSS.

For fully half a century the extensive nurseries that were formed at Waltham Cross by the late Mr. William Paul have enjoyed a fame that is world-wide as a home of the rose in its diversity of form and colour. The traditions of Messrs. William Paul and Son and the splendid work that is at the present time being accomplished, under the direction of Mr. Arthur W. Paul, in the development of roses fully justify the high estimation in which the firm is held by all classes of rosarians. Here have been raised large numbers of varieties, high in quality and of surpassing beauty; and here are grown in their hundreds of thousands, and with a high degree of success all roses of merit, without reference to the place or country of their origin. Necessarily, the varieties raised by the firm occupy large areas, for their qualities obtain for them a high degree of popularity, and consequently a large demand, but all would appear to be regarded with a similar degree of favour and grown in numbers proportionate to their merits. As one walks through the vast quarters devoted to roses, enjoying the distinctive charms of the many hundreds of varieties growing therein, and taking note of the splendid development of the plants, there is no difficulty in understanding why the nurseries should have become famous at home and abroad in connection with the cult of the rose.

The roses unquestionably fully deserve the high position that has by common consent been assigned them in association with the activities of the firm, but they do not by any means exhaust the great features of the nurseries. Take away the acres of roses, and there would be a great blank, but the removal of their dominant influence would bring into relief the collections of trees and shrubs that, by reason of their charm of habit, leafage, or flowers, are of special value for beautifying the garden and deserving of a considerable degree of attention. The value of ornamental trees and shrubs have long been recognised at Waltham Cross, and the writer remembers with pleasure the two lectures on them that were given by the late Mr. William Paul, one at the Horticultural Congress at Oxford in 1870 and the other at Birmingham two years later. He remembers also making the acquaintance at Waltham Cross for the first time of a considerable number of the most beautiful kinds that some thirty years ago were practically unknown to the general body of planters, being then seldom seen beyond the boundaries of botanic gardens and a few of the leading trade establishments, where, as in the case of these nurseries, special attention was given to trees and shrubs. One of the broad walks which intersects the nurseries is flanked on either side by moderate-sized specimens of large numbers of the finest kinds, and a leisurely examination of these, note-book in hand, during the summer season, would afford much pleasure to those interested in arborescent and ligneous vegetation, and have considerable educational value.

Not less important are the big areas occupied by fruit trees, which, on the rather strong soil, make free yet firm short-jointed growth, and produce fibrous roots with such remarkable freedom as to admit of their being transplanted without receiving an appreciable check. All kinds of fruit in cultivation are represented, as are all the forms in which the several kinds are grown, and their condition leaves no doubt upon the mind as to their having had the advantage of skilful manipulation. These points have been mentioned because in this relatively brief reference to the activities at Waltham Cross, it will not be possible to do much beyond passing under review the more noteworthy of the roses that have been raised by the firm. Without some such intimation the impression may be unintentionally given that the nurseries are almost exclusively devoted to roses instead of containing, as is the case, collections on a large scale of the more important classes of fruit trees, ornamental trees and shrubs, and hardy plants.

Roses.

In the examination of a list of the roses that have been raised and distributed by the firm during the past fifty years, one is impressed by the staying powers of a considerable proportion of the varieties. This point is of interest as showing that from the first the firm fully appreciated the importance of roses having a good constitution and blooming freely, as well as producing flowers of high quality. That it was regarded as essential to differentiate between roses required for exhibition and for garden decoration is made sufficiently evident by the following extract from the catalogue of roses issued in 1884: "It should be borne in mind that the exhibition roses, which are constantly before the public, in print, and at the flower shows are not always the best for garden ornamentation, or for the general purposes of house decoration, as such varieties often bloom

ROSE OPHELIA.

A beautiful hybrid tea, raised and introduced by Messrs. William Paul and Son. The flowers are of large size, and the colour salmon-flesh shaded rose.

more sparingly, and require a costly and troublesome system of management. The exhibitor is tolerably safe in picking his varieties from the stands at the exhibitions, as the grower of pot roses only will attain his object by selecting from pot plants; but the grower for all ordinary purposes of decoration will assuredly do better if he chose his kinds from under his eye in the open ground. Whether forming a new collection or adding to an old one, it is a good investment of both time and money to make a visit of inspection to the grounds of some one or more of the principal rose growers when the roses are in full bloom."

In turning to the last year's edition of the catalogue of the National Rose Society, it is found that of the Waltham Cross roses seventeen have a place in the selected list. These comprise Beauty of Waltham and Pride of Waltham, two excellent hybrid perpetuals, the first distributed in 1861, and the second in 1881; Fairy Queen, Hugo Roller, Medea, Morning Glow, and Sulphurea, five beautiful free-flowering tea-scented varieties; Beatrice, Earl of Warwick, Margaret, Waltham Climber No. 3, and Warrior, four hybrid teas of much value for the garden; Waltham Rambler, a charming multiflora, with rose-pink flowers; and last, but by no means the least, the wondrous hybrid briar, Juliet, which, by its distinct and effective colour and rich fragrance, startled rose lovers when it first made its appearance in public, and has continued to enjoy the popularity to which it attained on becoming known.

The four new roses distributed last year fully maintained the high standard characteristic of the firm's productions, and have already taken a prominent position in the estimation of rosarians and in their gardens also. Three of these are hybrid teas, two being of much value for forcing, and one is of great merit for exhibition, while all three are excellent roses for the garden. Taking them in alphabetical order, Mrs. Charles Hunter is a beautiful variety, with bold, finely-formed flowers of a brilliant rose-red colour when fully developed; the petals being large and handsome, and the stems long and carry the blooms erect. It is an excellent rose for pot culture under glass, and for the supply of cut flowers grown in the open. Nerissa has large flowers of superb form, the colour being cream-yellow, shaded with white at the margins of the petals and suffused peach colour in the centre; it should be highly popular for the distinct shade of colour it affords. In the garden it is highly effective. Ophelia is remarkable for its large, finely-formed flowers and the length of stem, ths latter characteristic greatly enhancing its merits for decorative purposes. The growth is vigorous, and, like Mrs. Charles Hunter, it is admirably adapted for forcing. The fourth of the new roses of last year is a dwarf polyantha, known as Coronet, and especially deserving of notice for its distinctness. The flowers are borne in large trusses, and are yellow, suffused with rose, and useful for decorative purposes in a cut state. The variety is also very effective in the garden.

Prominent among the roses that were introduced by Messrs. W. Paul and Son in 1911, are Florence Haswell Veitch and Frances Charteris Seton, two superb additions to the hybrid teas. The first-named has so vigorous a growh as to give it a first place amongst pillar and wall roses, and to render it suitable for culture in bush form. The flowers are of large size, moderately full, and rich scarlet, shaded with black. They have also the merit of being delightfully fragrant and produced freely and continuously. The second is remarkable for the large size, superb form, and the sweet perfume of its flowers. The colour is an effective shade of rose-red. Lady Downe, which also belongs to the year 1911, is regarded with much favour by those who appreciate buff-yellow roses, and deservedly so. The flowers are large, of excellent form, and borne on long, erect stalks. The colour is buff, rich yellow in the centre in the earlier stages of development, passing to pale yellow. It is a useful rose for both the garden and forcing.

The beautiful rose Bianca, of which an illustration is given herewith, is a notable addition to the list of hybrid teas. It is one of the many fine varieties raised by the firm, and will be distributed early in July next. The well-formed flowers are cream-white, tinted peach colour, and the buds are long and pointed. As a bedding and decorative rose it should attain a high degree of popularity, for it is vigorous in growth, free and continuous in flowering, and a good forcing variety.

Camellias.

For a long series of years camellias have constituted a great and highly interesting feature at Waltham Cross, and they have lost none of their attractions to those who appreciate beautiful flowers, irrespective of the influence of those who are unduly swayed by fashion. This outstanding feature is of exceptional interest from the fact that when camellias were banished from the majority of trade establishments and private gardens, Messrs. W. Paul and Son strengthened rather than reduced their collection, and the huge span-roof structure in which it is housed has annually been a source of delight to those who retained their appreciation of these beautiful shrubs. For a time the demand for camellias was unquestionably small, but it never died out, and for some years past there has been a distinct revival. The demand, however, has not been so great for cultivation under glass as for planting in the open, but it is probable that they will be more in request for glass culture when the beautiful semi-double and single varieties that have been introduced within recent years have become well-known. A goodly number of these have been raised from seed in the nurseries, while others have been introduced from Japan, and the varieties other than those with double flowers now form a large and attractive group.

Chief among the semi-double and single varieties, of which note was made a few days since were Adelina Patti, a beautiful single variety, the flowers soft salmon-pink, with white edge to petals; Waltham Glory, a single variety, bearing scarlet flowers, and having a fine habit; Apollo, semi-double, brilliant orange-scarlet, equal in effectiveness to Camellia reticulata, but a much better grower; Mars, semi-double, somewhat similar to the last-named, but the petals are a trifle reflexed; Vesta, single, scarlet, good; Juno, single, the flowers of medium size, pure white, occasionally flaked with rose, and produced with great freedom, the habit is remarkably good; Alba simplex, single, pure white, a charming variety; Minerva, single, bright rose-pink, free in flowering, and with fine habit; Novelty, single, white, freely flaked with rose; The Swan, single, the flowers white, with prominent clusters of cream-yellow anthers, and exquisitely beautiful, the flower-buds are long, and the habit of the plant good; Donckelaari, a well-known semi-double variety, with brilliant rose-red flowers, spotted and flaked with white, still occupies a prominent position in its class, and Lady Mackinnon is a distinct Japanese variety, with single flowers, the colour bright scarlet, occasionally blotched with white.

Very attractive as usual were Lavinia Maggi, one of the most beautiful of the double flaked flowers; Manera, a double variety, with finely-formed flowers of a rich orange hue, distinct and effective; Gilesi, a rich red flower, with anemone centre, and very attractive; Augustina superba, a double flower of an exquisite shade of pink; and Madame Ambroise Verschaffelt, a beautiful double blush-coloured flower, with pink markings.

Hollies.

The collection of hollies is extensive, and the splendidly developed specimens that flank the avenue, which extends the whole length of the nurseries, is especially deserving of study because of the opportunities they afford the planter for becoming acquainted with the habit of the leading kinds when full grown. As the time for planting these shrubs is at hand, brief notes on a few of the best can hardly fail to be useful. Silver Queen was made note of as one of the best of those with silvery variegation, being free in growth and bright in colour; Scotch Gold, a free-growing form of fine habit, rich in colour, and thriving under divers conditions; Gold King, a variegated form of Hodgkin's Holly, distinct, bright in colour, and very handsome; Handsworth Silver, a very fine holly, with silvery variegation, ranking next to Silver Queen in merit; Aureum pictum, one of the best of the Milkmaid hollies, which are less desirable than many of the other forms; Hendersoni is a green-leaved form, remarkable for the freedom with which it produces its berries even in unfavourable years; Myrtifolium is a charming small-leaved holly, useful for shrubbery borders of limited dimensions; Crenata is another desirable green form, with small leaves and moderate in growth; Balearica is an excellent green-leaved holly for southern towns, but it is rather too tender for the north; Walthamensis is a very distinct golden holly of moderate stature, the leaves broadly margined with gold, and in some instances are wholly of a golden hue; for small shrubberies it is especially useful because of its neatness and rich colouring.

G.

NOTES FROM KEW.

Forced Shrubs.

As might be expected at this season the different hardy shrubs that have been forced prematurely into bloom form a prominent feature of the floral display in the greenhouse. The Temperate House, too, is greatly brightened by a judicious use of flowering shrubs, most of which, despite the forebodings over the weather experienced last summer, are blooming with unwonted freedom. Pyrus floribunda, with its deeper-tinted variety atrosanguinea, as well as the allied Pyrus Scheideckeri, are unusually fine.

Azaleas of the mollis section, too, are freely represented, those of a warm orange or terra-cotta tints being always admired. Apart from any other consideration, the compact root system of this azalea enables it, when lifted in the autumn and carefully potted, to be gently forced without any risk. Prunus triloba, one of the finest of all shrubs for forcing, is freely represented, the long slender shoots being wreathed for some distance with pink rosette-like blossoms. Of shrubby spiræas the pretty white-flowered S. confusa or media is well-known, but two others not so generally employed may be seen at Kew. They are S. arguta, one of the earliest to flower in the open ground, and S. prunifolia flore plena, whose dark-coloured branches are wreathed with small double pure white blossoms. The rich golden, rose-like flowers of Kerria japonica flore plena impart quite a distinct tone of colour, as also do the pendulous racemes of Wistaria sinensis, which, from the manner in which the flowers are borne, is seen to the best advantage when grown as a standard. Of lilacs the variety Marie Legrange still holds its own as the best single white for forcing, while of the same tint the double Madame Lemoine is very fine. Whether in the open ground or under glass Charles 10th is a very desirable coloured kind. In the cherry family, Cerasus J. H. Veitch, with its large pink-tinged blossoms, is very showy.

Acacia hastulata.

This greenhouse acacia, which is also known as Acacia cordata, is a very distinct species, and withal well suited for growing in small pots. Its style of growth is some-

what after the manner of an epacris, that is to say, it pushes up long shoots of a partially upright habit and furnished with tiny triangular closely-packed leaves. The flowers, which are borne in the axils of the leaves, are of a pale straw colour, and so numerous that when at their best the leaves are almost hidden. It is about twenty years since this acacia was first taken in hand by some of our nurserymen, and turned out in the shape of neat, freely-flowered, bushy specimens.

Begonia Gloire de Sceaux.

This is a grand decorative begonia, and a group in the greenhouse shows it to considerable advantage. The plants, given space for their development, are more or less of a pyramidal shape, the large massive bronzy-tinted leaves being very attractive. In addition to this the rose-coloured blossoms are bright and cheerful. This begonia was first sent out about twenty-five years ago, at which time it was reported as a cross between B. socrotrana and B. subpeltata, but since then doubts have been expressed as to its origin. It is, however, a grand decorative begonia, coming in as it does at a time when many of the socotrana hybrids are on the wane.

Chorizemas.

A group of these free-flowering, hard-wooded plants forms a very pleasing feature in the greenhouse, in which structure they will flower throughout the winter and early spring months. The small brightly-coloured pea-shaped flowers, disposed in loose racemes, have a very pleasing effect. They are less particular in their cultural requirements than some other subjects of a hard-wooded character.

Grevilleas.

A good-sized bush of Grevillea linearis is planted out in a bed in the greenhouse. The leaves are long and narrow, with silvery undersides, while the flowers, which are freely borne in clusters, are white. As with many other grevilleas the long-curved style forms a notable feature of the inflorescence. Two species in the Temperate House also merit recognition, namely, Grevillea ornithopoda and G. punicea. The last-named, a compact bush, has blossoms of a light red and yellow colour, while G. ornithopoda is very distinct in habit, foliage, and in flower. The leaves, from whence the specific name is derived, are narrow at the base and widen out towards the apex, where they are divided into three, very suggestive of the claws on a bird's foot. The flowers are white and very slender. Trained up to a tall pillar the exceedingly graceful habit of the plant is seen to advantage, as the slender shoots hang down for a considerable distance.

Clerodendron splendens.

This climbing species from tropical Africa forms a very bright feature in the T range, where, trained to one of the rafters, it has been flowering for a long time. The flowers borne in loose cymes, are of a deep scarlet or bright crimson colour. It is an old species, but is by no means so generally met with as its merits deserve.

Begonia manicata.

Though the individual flowers of this Mexican species of begonia are but small, they are so numerous as to make a good display, and that, too, when many of the others are past. In the T range it is just now in good condition. This species forms a short sturdy stem, clothed with large handsome-lobed leaves of a bright shining green colour. The erect flower scape, which well overtops the foliage, is terminated by a branching panicle of light pink blossoms. There are two varieties notable for foliage distinctions, namely, aureo maculata, in which the leaves are blotched with gold; and cristata, whose leaves are crisped at the edge like some of the kales.

Columnea glabra major.

A specimen of this charming gesnerad forms a very bright and attractive feature in the T range. It forms a freely-branched shub a couple of feet or so in height, the shoots being clothed with small, ovate, hairy leaves, while the flowers in shape suggest those of the nearly allied genus œschynanthus. These are, however, natives of the warmer regions of the old world, while the columneas occur in the Western Hemisphere. That herewith referred to is a native of the mountainous districts of Costa Rica, where it occurs principally as an epiphyte. The flowers are about three inches in length and of an orange-scarlet colour.

Rhododendron cornubia.

A flowering example of this Rhododendron in the Temperate House shows it to be one of the best of the bright-coloured Himalayan hybrids. It was, as implied by the name, raised in Cornwall, the parents being the Himalayan R. arboreum and the hybrid R. Shilsoni. The flowers of cornubia are of a bright scarlet crimson colour. It was the only rhododendron to be given an Award of Merit by the Royal Horticultural Society last year.

Cytisus proliferus.

A large specimen of this member of the broom family, getting well on for 20ft. in height, is now flowering freely in the Himalayan portion of the Temperate House. It is a native of Teneriffe, and in the favoured parts of these islands will thrive out of doors, but, as a rule, it requires protection. The shoots are long and vigorous, and well clothed with silky leaves, while the flowers, which are freely borne from the leaf axils, are white. Being of a loose, rambling nature, this cytisus needs support, the specimen at Kew being trained to one of the pillars which uphold the structure. The "Dictionary of Gardening" gives the date of its introduction as 1779, but the same authority is greatly in error in giving its height as 2ft. to 4ft.

K.

ROSE BIANCA.

A charming hybrid tea, raised and introduced by Messrs. William Paul and Son. The flowers are cream-white, tinted peach colour.

SOME DWARF CAMPANULAS.

Under the above title it is not intended to include those species, like C. cerisia and others, which require special treatment, but only those dwarf and free-growing kinds that prove so valuable for furnishing the rock garden and border. The Bellflower family is such a large and varied one that a most interesting garden could be made entirely confined to the members of this genus alone. The flowering time extends over a long period, so that an effective display might be obtained from spring until well into the autumn months. In habit the species vary to a great extent, from tiny plants like C. cerisia, only an inch or so high, to giants like C. lactiflora, which in favourable situations attain a height of 8ft. or more. Those species and varieties mentioned below are a few of the more easily-grown and decorative plants suitable for many situations in the rock garden.

C. Portenschlagiana.

This charming little Dalmatian campanula, which is here illustrated, is burdened with a cumbrous name, but it certainly is one of the most useful of the smaller-growing members of a family that plays a prominent part in furnishing our rock gardens. Of free-spreading habit, in half-hardy or even in sunny positions, this Bellflower will soon cover a good space with its stoloniferous stems, which love to ramble amongst moisture-holding rocks or stones. In such positions it will produce masses of rich violet flowers from June onwards through the summer months. This species has often been confounded with the Italian C. garganica, quite a distinct species, with wide, open flowers. It is also known under the more acceptable name of C. muralis, and varies a good deal in the size of its bells. The Bavarian form bears the largest flowers, and is also very vigorous in habit; it is known either as var. bavarica or var. major.

When planting C. Portenschlagiana should be provided with a gritty compost of loamy soil, to which should be added some broken limestone. It does not appear to ripen seeds; at least, I have never seen any yet. However, it may be propagated readily by means of division in autumn or spring, or cuttings in summer. It is a native of Dalmatia, and found on rocks and walls.

C. carpatica.

The Carpathian Bellflower is deservedly one of the most popular garden plants; it is so easily grown and so very floriferous. The type forms a neat tuft of stems and foliage, with fair-sized blue flowers on stems about nine inches high. In gardens there are numerous beautiful varieties, some with very large flowers. They vary considerably when raised from seed, so that forms may be multiplied indefinitely. Some of the most distinct are: White Star, with large white flowers; pelviformis, with flat, saucer-shaped flowers of a pale blue colour; Riverslea, very large, somewhat flat flowers of a deep blue shade; and turbinata, similar to the last, with rich blue flowers of large size, and a dwarf compact habit. Many others have been offered in catalogues, but they are more or less similar to the above, environment and conditions under which they are grown making a considerable difference.

C. garganica.

A very dwarf plant is the Italian Bellflower, forming tufts of dark green, shining foliage, only two inches high. These are covered from May to July with numerous wide open, starlike flowers of a pretty blue-lilac shade. It is a good perennial, and quite hardy, although often suffering from too much damp in winter if not provided with copious drainage. Like the Dalmatian Bellflower, it is an excellent subject for walls, planted between the loose stones. C. garganica grows on Mount Gargans in the fissures of rocks and old walls, in full sun. It seems to be strictly limited to this locality, not having been recorded elsewhere, although its closely-allied species, C. Portenschlagiana, is found on the other side of the Adriatic some hundred miles away.

C. garganica var. hirsuta is an attractive form, with very hairy foliage, and is still more impatient of damp than the type. It should always be planted in the fissures of vertical rocks. The white form of the latter is a pretty companion.

C. pulla.

C. pulla, from the Alps of Austria, is a beautiful little tufted species, forming a regular turf by means of its numerous

CAMPANULA PORTENSCHLAGIANA.
A beautiful plant for the rock garden or border; it bears violet flowers.

stolons. It enjoys a porous soil, rich in humus, mixed with small granite chippings. Spreading rapidly it is one of the campanulas that repay for replanting, as all the stronger growths are found on the outside of the patch, the centre portion becoming weak and exhausted. The large, deep violet, drooping flowers are produced singly on stems during the summer months, and are very attractive in a partly-shaded position in the rock garden.

In cultivation there is a stronger-growing plant closely allied to this species, which is known as C. pulloides, and is evidently the result of a cross with C. carpatica. C. G. F. Wilson, in both forms, with green or yellowish foliage, is also the result of the same cross. Both forms are very dwarf, free growing, and floriferous.

C. pusilla.

One of the prettiest and most popular kinds is this charming little bellflower, which is found over a wide stretch of the Alps. It is usually met with in calcareous regions, growing in mountain debris and glacial moraines at altitudes varying from 1,000 feet to 6,000 feet. In places it forms large turf-like carpets, covered during the whole of the summer with its drooping flowers of blue or lilac. One of the easiest of campanulas to grow either in the rock garden or border, it is certainly a most decorative and useful plant. Gritty, but rich soil should be provided when planting, and although it will do in full sun, it is more partial to a semi-shady position.

A pretty variety is the pure white form, C. pusilla var. alba, and recently another has been distributed under the name of Miss E. Willmott. The latter, however, is only a selected form of the well-known C. pusilla var. pallida, which has long been grown in gardens.

Other Kinds.

In addition to the above there are many other dwarf-growing species which are quite easy to grow. There is C. Allioni, from the Alps of Dauphiny and Piedmont, which only needs a very gritty soil. Its large violet bells are very handsome, growing singly on short stems, and it spreads rapidly by means of stolons. The Bearded Bellflower, C. barbata, is also well worth a place, planted in a non-calcareous soil. From the Caucasus we have recently received several welcome additions to this family, among which are C. Raddeana, a low-growing plant with large blue flowers, and C. imeretina, a plant in the way of C. sibirica, but more compact in habit. Another species from this region is C. bellidifolia, which is somewhat like C. Stevensi. As they both hail from the Caucasus they are possibly forms of one species. A useful later-flowering and beautiful plant is C. Stansfieldi, which may be described as a glorified C. Waldsteiniana. It is of dwarf compact habit, with rich violet-coloured flowers in autumn.

W. IRVING.

Kew.

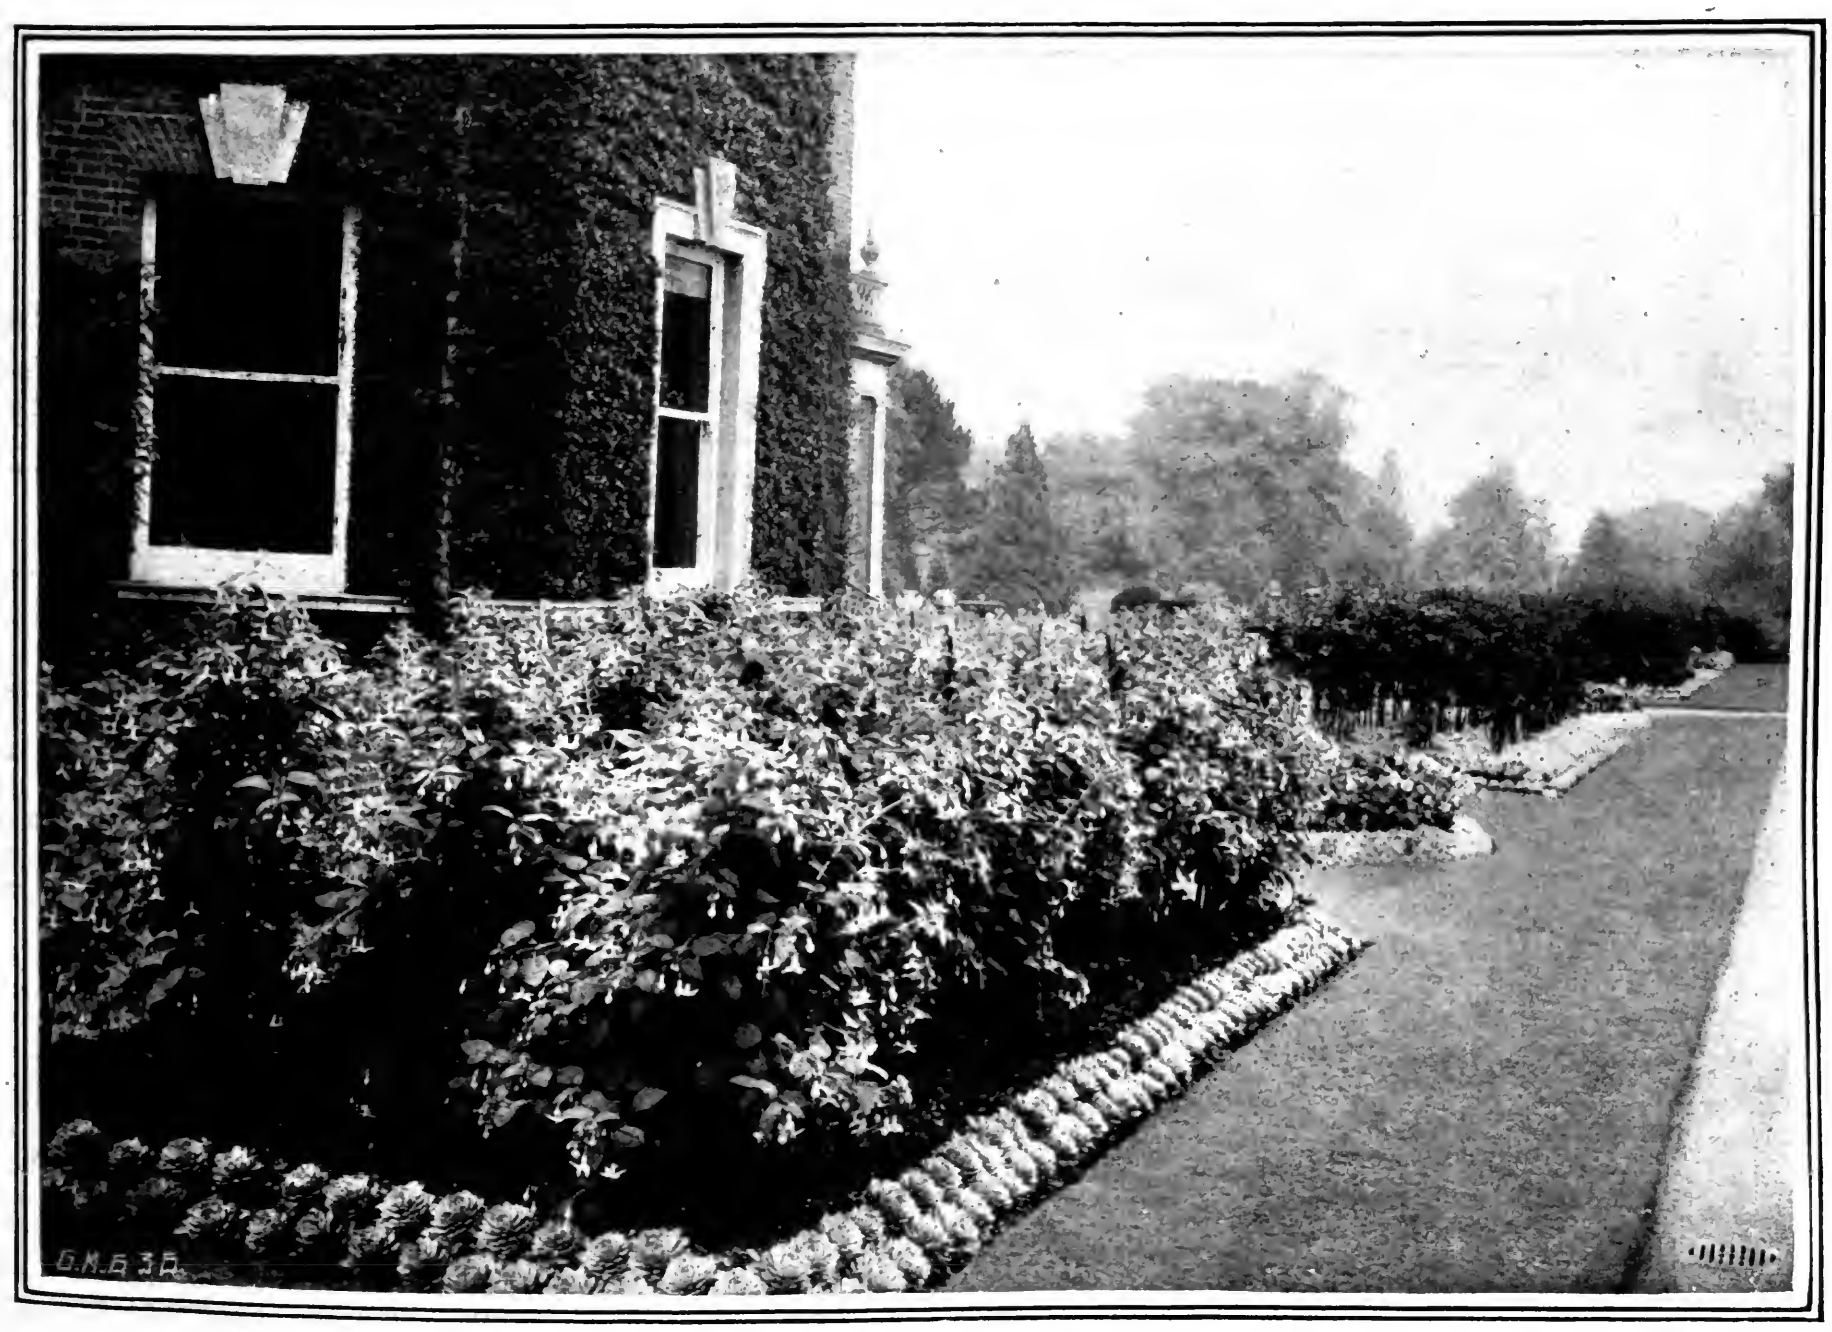
Cucumbers.—Great care and attention is necessary to maintain an unbroken supply of cucumbers at this season. The plants require to be lightly cropped, thinly trained, and moderately top-dressed with warm compost whenever the roots appear on the surface, and otherwise encouraged by occasional waterings with warm, weak liquid manure. Fresh seeds should be sown at once in small pots, which should be plunged in a hotbed of 80 degrees, placing them later near the glass in a temperature of 68 degrees. Prepare for the reception of these plants by cleansing the pits and preparing the materials for fresh beds, repeating the above temperature, and maintaining a generally humid atmosphere by frequent dampings of the path and beds.—F. JORDAN.

BEDDING FUCHSIAS.

The present-day style of summer bedding is vastly different to what was practised twenty years ago, and, naturally, a different class of plants has been brought into being. Illustrations of what I refer to have quite recently appeared in the pages of GARDENERS' MAGAZINE, as well as previously, with notes upon subjects especially suitable. But my remarks hereunder refer particularly to fuchsias.

There are several reasons why fuchsias are so valuable for summer bedding, and I will mention a few. Present-day arrangements do not stop at evenly arranging plants of one height as formerly, but it is now customary to use standard plants of varying heights over a base of some plant, flowering or foliage, eminently adapted for carpeting the soil. For these standards various plants are brought into use, and while fuchsias cannot be used entirely for the purpose, their diversity of flower and foliage enables them to play a prominent part. For freedom of flowering they are unsurpassed, and may be relied upon to provide a continuous feast of flowers until autumn frost puts an end to the general scheme. Here, again, they score over the many other and somewhat less tender subjects, because they are indifferent to the climatic conditions, and the flowers are not hidden by superfluous foliage in moist seasons.

Fuchsias for bedding, as standards, are easily and quickly grown from cuttings, and even when a stock is already established for the purpose, I would recommend each year raising a few young plants, so that the oldest may be dispensed with, and younger and more vigorous ones of uniform size take their place. These are easily rooted in the autumn, and kept gradually growing during the winter in a warm greenhouse temperature, and shifted on as



FUCHSIAS IN THE FLOWER GARDEN AT ALDENHAM HOUSE.

required, they will make nice plants. Fuchsias are not very exacting, and when they have done duty in the flower beds, if they have been plunged in their pots, they should be lifted, have the roots trimmed off as near the pot as possible, be pruned back to the hard wood, and stood during the winter months in a cool frost-proof shed or pit. If the plants were turned out of their pots at planting time, then put them into the smallest receptacles possible, making them quite firm at the root after considerably reducing the ball; if at all dry, give a thorough watering. They will need but little water until the buds begin to move next spring, when they should be kept a little warmer, and also be syringed freely on bright days. They must not be allowed to crowd one another at the time, or the plants will suffer, and as the days lengthen air must be more freely admitted and the plants gradually hardened, making quite sure before they are finally placed out of doors that they will receive no harm.

The following varieties are those which we grow here, and include, I think, most of those best suited for the purpose, though I have no doubt there are others of equal merit. Some of these fuchsias are to all intents hardy, but, excepting in very favoured localities, it would not be wise to leave them out of doors throughout the winter months.

Brilliant is a splendid variety for bedding, having double flowers, with reflexed sepals of a rich deep red, the corolla violet, shaded with red. Ballet Girl is another double-flowering variety with immense flowers of great substance; the sepals are bright red, corolla white; a beautiful and most effective variety, and a splendid bedder. Jubilee Queen is a single variety somewhat resembling Lye's Own, with white sepals and tube, and deep red corolla. F. Coffe has a red tube and sepals, and blue centre; it is a splendid variety for bedding. Wave of Life is a most attractive variety, possessing golden foliage, which renders it the more conspicuous, when blended with other suitable subjects. The flowers are single, freely produced, and the tube and sepals are a pleasing red shade, with a blue corolla. Lye's Own is a single fuchsia with white tube and sepals, and red corolla. Madame Cornelison, an old variety, has a white corolla and carmine sepals, and is yet one of the best.

Audenkenan H. Henkel, which we, to save time, call Henry Henkel, is one of the best, with salmon-red flowers. Thalia is another variety belonging to the same section as the last. Coralle, a most attractive variety, and one that has been admired here as much as any, is free flowering, with blooms of a beautiful shade of coral-red, and particularly handsome foliage. Gottingen is another variety with salmon-red flowers, and Mary has coral-red flowers and distinct foliage.

The above five varieties of hybrid fuchsias are each excellent, and may be bedded with the best possible effect. They flower with remarkable freedom, and form quite a feature when massed together in a bed by themselves, or interspersed with other plants; and, in addition to their strikingly handsome flowers, the foliage is most attractive, giving numerous green and bronze shades.

EDWIN BECKETT.

Aldenham House Gardens.

Early Turnips.—A sowing should be made on a mild hotbed. Early Long Frame or White Forcing will be found suitable varieties for this purpose. Turnip seed germinates very quickly, and care must be taken that the young seedlings are afforded air before they become drawn in growth; thin out the plants at any early stage.—W. MESSENGER.

AMONG THE ROSES IN FEBRUARY.

February is one of the most important and busy times among roses under glass, and the future result of almost all early forced plants depends, in a great measure, upon their present treatment. There are few subjects so difficult to bring into first-class order as roses that have not had the benefit of correct treatment during the first part of their new growth.

Roses Under Glass.

A few hints upon potting and pruning have already been given, and by the end of the month all the plants should be in active growth if the blooms are to be of real service. The only instance in which I would keep roses back as much as possible is when they are in unheated structures. Unless we can retard these somewhat it is by no means an easy matter to keep the tender young foliage safe from a spell of cold or very dull weather, without any aid in the way of artificial heat. It is when the dampness of early morning hangs upon the foliage for a long time that much of the damage is done, and at the risk of having the atmosphere a little colder than seems desirable, I would use the ventilators carefully, with the object of dispersing this chilly dampness as soon as possible.

Great care in watering, never giving water except when quite necessary, and then early in the day, will do much towards checking this early-morning moisture, which often hangs upon the foliage like very heavy dew in unheated rose houses. I do not think we can pay too much attention to a rather dry night atmosphere, and it is an undoubted fact that more cold can be borne by the plants when dry than when there is a tendency to excessive moisture. In conveniently heated houses also I would advise a somewhat drier morning atmosphere than many maintain. We can easily have moisture when needed, and it is not as though the foliage had to fortify itself against a parching summer day's heat.

So many instances have come before me where the check to growth could be plainly traced to the resort to extremes in the matter of liquid and other stimulants, in fumigation, and in the use of too strong an insecticide, that I need make no excuse for again warning against these extreme measures. It is such a folly to hopelessly harm the growth and its prospect of future blossoms, simply by using too stringent measures to destroy a few insect pests. If properly watched for these latter will be discovered as soon as they put in an appearance, and if tackled promptly no great strength of insecticide is necessary. At this dull time of the year I am a staunch advocate of weak fumigations, which should be used in conjunction with the syringe as soon as possible on the following morning.

Pruning.

It is very early to mention pruning, but the plants are so forward in some instances that I would like to say a word against undue haste because of this. Instead of an inducement towards an earlier use of the knife, it should make us all the more reluctant to prune. Some few of the older varieties, also the Scotch and Rugosa sections, may, perhaps, receive a little pruning, but these need scarcely any. On the other hand, to cut away wood because the tips of these growths are precocious does not accomplish any desirable end. In fact, it is apt to encourage just what we do not want, viz., too early development of the more valuable basal buds that are our chief asset in the production of good blooms. At present these top growths and buds, that are breaking so freely, really act as a safety valve to this all too early flow of sap, and leave the lower buds far more dormant than would otherwise be the case.

In all sheltered positions the more evergreen sections and varieties of roses have not ceased growing all through the winter, and, doubtless, this will account for the great impatience of many frends to have their roses pruned soon. Nor is there the waste some of them apparently think, for in almost all cases we should be cutting away the wood carrying these abnormal growths in the ordinary course of pruning, whether they are active now or not. I shall keep my knife shut up all through this month. There is one exception, however, and that is where long rods of climbers are to be secured to walls, fences, or buildings. Here we can do no harm, the main point being to secure the long rods of growth made during the previous summer and autumn, and I would certainly proceed with this work as suitable weather allows.

Planting Rose-stocks.

At the close of last month's notes upon outdoor roses I mentioned the early spring planting of dwarf stocks. Why we plant now, instead of autumn, is to avoid the risk of severe frost upon the stems of rooted dwarf stocks made from cuttings. We must remember that these cuttings have been buried in the soil from the previous autumn, and all through winter and summer; therefore, to expose soft bark that has existed under such softening and tender conditions to the trials of winter does not seem reasonable; and all the more so because they are already rooted, and do not need the same opportunity to do so as in the case of standard briar stocks from the hedgerows. This is why we keep back the cutting stocks, whether these be from the briar, Manetti, De la Grifferaie, or any of the polyanthas used for that purpose, and plant them after the severest part of the winter has, in all probability, passed. On the other hand, seedling briars do not run the same risk of injury at the crown, but even then I prefer waiting for a more settled soil, and until the dangers of winter are over, and such troubles as hares and rabbits have something more attactive to occupy their attention. I have often seen beds of autumn-planted stocks seriously injured by winter frosts and the visits of rodents, which are often very frequent during periods of severe weather.

Plant with some little thought as to the class of growth to be worked upon the stocks. Three small beds at differing distances apart is much the best method. For instance, stocks nine inches apart in the row, and rows eighteen to twenty-four inches from each other; a second bed twelve inches from stock to stock, and rows two feet apart; and a third bed three feet from row to row, with the stocks a foot or a little more apart, will afford a good choice for the various heights and growth of the varieties. Always plant dwarf stocks as shallow as possible, to afford greater facility in putting the rose buds closer upon the crown of their roots. The fuller treatment of pruning may safely wait until next month, when I hope to be able to deal with it.

RECENT ADVANCES IN HORTICULTURE.

(Continued from page 112.)

Commercial Horticulture.

In the domain of commercial horticulture there have also been many changes and many important developments in recent years, but the general tendency in this branch of horticulture is specialisation. One grower specialises in, say, ferns; another takes up, say, roses; another, chrysanthemums; another, carnations; another, orchids, and so on, for it is only by specialising that the best results can be obtained. Ferns are now grown commercially for house decoration by the million, and it would be very difficult to even guess at the number sent out yearly from commercial establishments in the case of roses, carnations, and chrysanthemums. The forcing of bulbs and other plants for commercial purposes has now become a very large industry, and the area covered by glass structures for forcing and other purposes has increased at an enormous rate in recent years. In comparatively recent years the opposite process of retarding has made great progress, and by these two processes, forcing and retarding, it is possible to have certain plants in flower almost at any time of the year.

In commercial horticulture competition is keen, but if the cutting of prices has hit some hard, it has at the same time had the effect of raising the quality of the article, and it is only by producing a better article that competition can be successfully met. In some lines foreign competition has made great headway, and, in the case of articles which require a somewhat better climate than ours, probably this will always be so; but where better climatic conditions are not necessary, provided he enjoys something like equal terms as regards the cost of production, the British grower ought to be able to compete successfully with foreign or Colonial produce.

French Gardening.

Another branch of commercial horticulture which has received some attention lately in this country is what is known as "French gardening." It is too early to say yet whether it has come to stay or not, but it has a special interest for those who are engaged in the growing of vegetables for market, as it enables them to produce certain kinds at times of the year when they are not obtainable by ordinary methods of cultivation. But the initial cost, as well as the annual outlay, must be heavy, so that it would require to yield a very good return to be sufficiently attractive as a commercial concern.

Fruit Growing.

As an industry, fruit growing in this country has not made so much progress as some of the other branches of commercial horticulture, and for this there may be reasons, climatic and economic, but there does not seem to be any drawback to it otherwise. Of course, when we come to fruits which require to be grown under glass, the case is different, the cost of production probably being too great to enable growers to compete successfully with cheap foreign and Colonial produce in the open market; but when we come to hardy fruit, like apples, there seems no reason why we should not be able to do so. No doubt, we have yet a great deal to learn regarding the grading and packing of fruit for market, and there is no doubt that it is their splendid methods of handling fruit which have given the Canadian and other fruit growers such a strong hold on our markets. It therefore behoves us to do our best to improve not only our methods of growing, but also our methods of dealing with the fruit after it is grown in order that we may be able to cope with the foreign and Colonial article.

Implements and Appliances.

As regards horticultural appliances, there is always some advance being made, though several of the commonest implements, like the spade, hoe, and rake, are practically the same as they were fifty years ago. In hot-house building, material has been lightened, with the result that the houses are better adapted to the purposes of plant-growing than were the heavily-timbered structures erected about the beginning of the last half-century. In one respect, however, little change has been brought about in recent years, and that is in the method of heating plant houses. Boilers innumerable have, no doubt, been put on the market, each claiming to have some superiority over all others, but here the change ends. Heating by low-pressure hot water circulation is practically universal, and it seems to meet all requirements; and, however much apparatuses may differ from each other in detail, the principle is the same in all of them. There is one aspect of the matter, however, to which the attention of inventors may be directed, and that is to the method of heating the water. The petrol engine has made aviation and other modes of locomotion possible, and it is not surely beyond the bounds of possibility that some simple method of using oil fuel of some sort may yet take the place of coal in horticultural and such like heating, and that the grimy stoke-hole and the smoky chimney may some day be a thing of the past.

Among implements, probably the greatest advance has been made in connection with the lawn mower, and this again the petrol engine has made possible. The motor lawn mower has come to stay, and where extensive mowing operations are necessary, it is a great advance over the horse-drawn machine. The advent of the lawn mower sounded the death-knell of the scythe, and with its passing there also disappeared the art of mowing, an accomplishment of which every young gardener was proud fifty years ago.

Diseases and Pests.

Great progress has been made in our knowledge of the diseases and pests which attack our plants and crops, and of the means of exterminating them. Much useful information regarding these matters is now disseminated by the Board of Agriculture by means of leaflets, which are supplied free of charge, and no gardener need therefore want for information regarding the commoner diseases and pests, at any rate. In the methods of fighting both diseases and pests, also, inventors have come to the aid of the horticulturist, and spraying appliances of the most up-to-date description are now to be had everywhere. In fact, with our knowledge of the diseases and pests and their ways, the effective means at our command in the way of insecticides and the various kinds of apparatus for applying them, we ought to be in a position, one would almost imagine, to exterminate anything and everything in the shape of plant enemies, insect and fungoid alike. But it would almost seem that the more we wage war on some of them, the more formidable do some of the others become, and this just reminds us that by destroying the balance of nature we sometimes bring incalculable mischief on our heads. It therefore requires both knowledge and discrimination in dealing with matters of this sort.

Literature and the Press.

In no way has there been a greater advance in recent times in horticulture than in the literature of the subject, and in this, as in the practice of horticulture itself the general tendency is towards specialisation. Since the days of Loudon and McIntosh, the number of works on general gardening has been comparatively small, but in recent years work on special subjects have been produced in bewildering profusion; in fact, it is difficult to make a selection from them. And the price at which they are produced is marvellously low compared with what used to be the case. I will only give one illustration of such books, viz., the "Every Day Gardening" series, published by an Edinburgh firm, which contains volumes on almost any class of plants. And the same remarks apply to the gardening Press, which, thanks to the wonderful development in photographic and other printing processes, is now profusely illustrated with all that is best and latest in horticulture, and at a price which brings it within the reach of all. Our leading gardening papers are not equalled by any other gardening papers in the world.

(To be continued.)

EXAMINATION OF PARKS EMPLOYEES.

The Royal Horticultural Society's eighth examination of employees in public parks was held on January 6, and, as previously, the examination was partly viva voce and partly written, occupying three hours and twenty minutes. It was held at the society's hall in Vincent Square, Westminster. Thirty-four candidates entered, and of these 10 secured places in the first class, 14 in the second, and 6 in the third, leaving 4 who failed to satisfy the minimum requirements.

The examiners report that the answers in the viva voce section were, generally, above the average, but the written answers show no very marked improvement on those of past years. Some of the candidates were weak in a knowledge of the functions of roots and leaves. The question on the drainage of heavy soils, was well answered, but that on the manuring of lawns and of different types of land, and the action of lime upon soils and plant foods, required a more scientific knowledge, and was not well answered. The study of artificial manures is important, and candidates should familiarise themselves with their use, especially as an adjunct to farmyard manure, and also of the quantities of each to be used.

There was a surprising ignorance concerning the utility of bastard trenching, and of the labour required for a specified area; and it was not a little disappointing to find only the oldest and commonest trees and shrubs mentioned, whereas so many excellent new varieties are now to be found in public parks. Five candidates omitted to answer the obligatory question, for which omission a certain number of marks was deducted.

The impression left upon the minds of the examiners, after the papers were marked, was that the information given showed but a fragmentary knowledge, uncertain and lacking conviction, instead of an exhaustive mastership of the subjects of the questions. Public parks gardeners are urged to recognise the value to themselves of a full and complete information, and of the knowledge born of the practical application of such information in their work. This is not to be gained by a month or two's book-reading before the examination, but by continued and persevering application to work and study and observation throughout the twelve months.

The attention of the first-class candidates is called to the society's general examination, which it is hoped they will prepare for, as inviting a higher standard of gardening ability.

CLASS I.

1. J. F. Goaman, North Finchley.
2. W. Power, Victoria Park, and G. J. Rule, Wandsworth Common.

14. F. Cobbold, Dulwich.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

THE COOL HOUSE.—Among the odontoglossums we find the bulk of the plants in their most active state of growth. Some will have completed their pseudo-bulbs, and will have their flower scapes in various stages of development; these require constant watching to protect them from slugs, thrips, and other insect pests. It is a difficult matter to keep slugs in check, and the safest plan is to lay lettuce leaves, small portions of bran or brewers' grains about the stages, so that the pests may be caught with the aid of a light at night, and destroyed. Pieces of cotton wool twisted round the base of the spikes forms a barrier which is not easily surmounted, but does not altogether protect the flower scapes from attack. After a practically sunless summer and unfavourable winter conditions, the pseudo-bulbs will be sappy. It is desirable to place all plants that are in a backward state and have their flower scapes advancing where they may obtain the maximum amount of light, with due consideration, of course, to protection from actual scorching. It will not only be found that the flowers are poor when produced from improperly matured growths, but it will also be found, in many cases, that the succeeding growths are not satisfactory, and such bulbs and growths are more liable to attacks of insect pests than is the case with thoroughly hardened growths.

FLOWERING PLANTS.—We should also consider wheher our plants are capable of carrying full spikes of flower. I am thoroughly convinced that it is a great mistake to expect too much from odontoglossums. When a full spike of flowers is taken from a plant for two or three seasons in succession we make but little advance in the size and quality of growth and pseudo-bulb, in fact we are more likely to find that, after such treatment, there is deterioration. It is all very well to cry out about disbudding of flower scapes, but it is possible that those who cry the loudest in this respect take good care to nurse their plants, by the entire removal of spikes, until the plant has become sufficiently robust to carry a full spike of bloom. There is no doubt that a great deal can be done to assist the plants by disbudding, and with the choicer kinds, where the increase of stock has also to be considered, it will prove to be a still greater advantage. Seedlings flowering for the first time should always have their flowers kept down to one or two on the scape. This will be ample to determine the quality, and there will not be any apparent loss of vigour in succeeding growths. This disbudding should be done as early as possible.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CLIMBING ROSES.—As these are now showing their flower buds they must be given plenty of stimulants. If growth is at all inclined to be congested it must be liberally thinned, or the flower stems will be weak. A surface dressing of well-rotted manure will be beneficial, and the feeding properties of this should be washed into the soil with tepid water as soon as it is put on. A sprinkling of soot should be scattered over the manure before watering. If mildew appears, dust the affected parts with flowers of sulphur. Aphis may be destroyed by fumigating with a nicotine compound.

ROSES IN POTS.—As the early batches pass out of flower they must be placed in a cold house for a week or two preparatory to standing them out in the open. It is important to keep these free from insect pests, therefore, if they are affected, measures must be taken to clean them. The plants which are coming into flower must be carefully watered, using liquid manure, soot water, or some approved fertiliser, as the case demands. Great care must be exercised in ventilating the structures containing roses, as cold draughts must be avoided. Fire-heat must not be used excessively at any time.

CANNAS.—The plants which have been resting may now be brought out and started into growth. The roots must be shaken out and repotted in suitable sized pots. If propagation is desired the roots may be carefully divided and put into small pots and plunged in a moderately warm hotbed. Propagation may also be effected by seeds, sown singly in small pots. The canna is a gross feeding plant, and to secure the best results the rooting medium must be of a very rich character. Loam, leaf-soil, well-rotted manure, and crushed bones, with a good sprinkling of coarse sand, forms a suitable compost. When the plants have made plenty of roots they will need copious supplies of water. Stimulants must also be given them at this stage, increasing this in strength as growth advances. Keep them growing in a light structure near the glass, in a temperature of 60 or 65 degrees until the spikes begin to appear, when they may be given a greenhouse temperature.

BEGONIAS.—The tubers which have been resting during the winter may now be started into growth. Extra large tubers may be divided with a view to increasing the stock. The tubers may be placed in leaf-soil in boxes till growth commences, when they must be put singly into 5in. or 6in. pots in a compost of loam, leaf-soil, and sand. Keep the plants growing in a temperature of 65 degrees, syringe them with tepid rain water, and keep the atmosphere moist until flowering commences, when cooler and drier conditions will be necessary. Seed may now be sown in shallow pans. Fill the pans with a compost of loam and leaf-soil in equal parts, mixing plenty of silver sand with it. The compost must be passed through a fine sieve. Sow the seeds carefully over the surface and sprinkle a small quantity of sand over them. Place the pans on a hotbed, and keep them covered with a piece of glass and shaded.—E. HARRISS, Lockinge Gardens.

HARDY FRUITS.

STRAWBERRIES.—Planting from the nursery beds may still be carried out on good land. Plant firmly, when the land is not too sticky, and allow ample room for the full development of the large, strong-growing varieties. Those intending to make use of plants that have been forced should have the land thoroughly prepared some few weeks prior to planting. Strawberries delight in a firm grip, and soil in good heart. These forced plants should not be kept in their pots longer than is just necessary to harden them a little, and more space should be allowed than for smaller plants taken from the nursery stock. Clean over all the older beds thoroughly, dust soot among the plants, and finally mulch with suitable manure.

ALPINE STRAWBERRIES are very useful, and often much appreciated for their refined flavour. Some varieties may be increased by runners, while others must be raised from seeds. If raised from seeds, procure a good strain from a well-known firm, and sow at once in pans filled with good sandy soil, pressed firmly. Stand the pans in a gentle warmth, and cover with a square of glass and paper, until the seeds begin to germinate. Strong plants put out in April should fruit in autumn.

GRAFTING.—Attend to this work as soon as the bark parts freely from the stock. Several grafts will be required for large trees, and some of the headed-back branches will be better with two or three grafts, according to their thickness. Graft good varieties only, and after inserting the scions see that they are neatly bound before claying.

CUTTINGS OF GOOSEBERRIES, CURRANTS, ETC., that were inserted in beds suitable prepared at the end of last season, will need to be looked over, making each firm should they have become somewhat loosened by frost. Push the stems down, and tread by the side of the lines so that the soil is very firm. If the soil is not too wet run the Dutch hoe between the rows, keep the whole clean, neat, and the bushes properly labelled. In all gardens it is advisable to propagate a few of the best kinds annually—to replace older, worn-out bushes. Plants struck a year ago will need more room; plant them in beds, or in lines on some suitable land, allowing 12in. from plant to plant, and 2ft. between the rows. Prune a little to ensure neat bushes for planting permanently in the coming autumn. Good varieties of gooseberries are: Whites—Howard's Lancer, Antagonist, Langley Gage, Whitesmith, and Transparent (white); London, Speedwell, Crown Bob, Dan's Mistake, Whinham's Industry, and Warrington (reds); Leveller, Golden Lion, Keepsake, Trumpeter, and Golden Gem (yellow); Hedgehog, Greengage, Telegraph, Shiner, and Surprise (green). Red currant—Raby Castle, Fay's Prolific, River's Late Red, White Dutch, and Transparent. Black currants—Baldwin, Boskoop Giant, and French Black. H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

ONIONS.—For this crop the ground requires to be well manured and deeply dug; no better site can be wished for than that previously occupied by celery, and it is only necessary to apply a dressing of well-rotted manure and dig the ground one spit deep. When the soil is dry enough to be easily worked, it should be levelled and made firm by treading. Prior to sowing the seed, a good dressing of soot should be scattered over the surface and well raked in with a wooden rake. If possible, the sowing should be completed by the middle of March, when the soil should work freely, and admit of the drills being drawn at an even depth. If the weather be wet the operation should be deferred until a more favourable opportunity occurs. Sow the seeds thinly and as evenly as possible, in shallow drills about one foot apart, lightly press in the seeds with the back of the rake, and cover them with soil, and lightly rake over the bed to make a neat finish. Among the many excellent varieties are Improved Reading, Bedfordshire Champion, A1, Brown Globe, James's Long Keeping, and Nuneham Park. Where large bulbs of mild flavour are desired, Ailsa Craig, Cranston's Excelsior, and Rousham Park Hero may be recommended. Autumn-sown onions may be transplanted at the first favourable opportunity on well prepared ground. The rows should be one foot apart and the plants set out nine inches apart; this distance may be curtailed or extended according to the size of bulb desired.

TOMATOES.—Plants from a December sowing will be ready for a shift into 6in. pots. The potting soil should not be too rich, as it is desirable to promote short, sturdy growth; good turfy loam, with some finely broken old lime or plaster rubble, and a six-inch potful of bone-flour per barrow-load of loam, will insure satisfactory growth. Stake and tie the plants as required, and place them near the glass in a sunny position. Young plants from recent sowings should be dibbled into the centre of small 60 pots, or into boxes, well watered in, and, if the weather be bright, shaded until they commence to root. Water should be given in moderation to pot plants until the soil becomes filled with roots. Afford a night temperature of 60 degrees, with a corresponding rise during the daytime; admit air on every favourable occasion, as excessive humidity of the atmosphere will cause soft, sappy growth.—W. MESSENGER, Woolverstone Park Gardens.

ENORMOUS DEVELOPMENT of the BIRMINGHAM SHOW, Friday and Saturday, July 18th and 19th. £600 Cash Prizes and Trophies. SHALL YOU BE THERE? Schedules (post free) from Secretary, WILLIAM G. CARRADINE, F.R.H.S., Birmingham.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

Notwithstanding a bitterly cold north-east wind, and a snowstorm the previous night, there was a quite good show at the Royal Horticultural Hall, on Tuesday, February 18, and during the afternoon the hall was crowded with visitors. The rock garden displays and collections of hardy flowers grow somewhat monotonous, the same style of arrangement and the same kinds of plants being repeated time after time. Orchids were not numerous, but daffodils were quite gay, and vegetables were of great interest, while primulas and azaleas and ferns were largely exhibited.

FLORAL COMMITTEE.

A very beautiful exhibit of primulas was set up by Messrs. Sutton and Sons, Reading. The grouping of the colours and varieties was very interesting and educative; a few leading varieties were Brilliant Rose, Majendie, Coral Pink, Sutton's Lavender, The Duchess, Giant Crimson, Crimson King, Giant Pink, Reading Blue, and the very fine deep purple-blue variety named The Czar. A very bright exhibit of rhododendrons from Messrs. R. Gill and Sons, Falmouth, was greatly admired because of its fine trusses of Rhododendron Cornubia, R. ciliatum, R. barbatum, etc., and its colony of Primula Winteri. Messrs. H. Cannell and Sons, Swanley, contributed a collection of cut zonal pelargoniums staged in glass vases.

A first-rate exhibit of finely-grown ferns, made by Messrs. J. Hill and Sons, Edmonton, was greatly admired, and it contained excellent specimens of the elegant Davallia tenuifolia Veitchi, Osmunda javanica, Nephrolepis exaltata superba, the bold Platycerium æthiopicum, Davallia repens—a grand plant, Asplenium serra, and Davallia fijiensis elegans.

Boronia megastigma lent fragrance to the group of greenhouse-flowering plants submitted by Messrs. Jas. Veitch and Sons, Chelsea. Cineraria Matador, rich scarlet; C. Feltham Beauty, and C. Pompadour, a fine strain of cyclamens and Tillandsia Lindeni all went to make up a bright collection. A handsome bank of Indian azaleas, both dwarf and fairly tall standards, was arranged by Messrs. Jas. Veitch and Sons, Chelsea; Mdme. Van der Cruyssen, rosy mauve; J. T. D. Llewelyn, pink; Apollo, scarlet; and Niobe White, with the blush and rose Vervæncana were a few of the leading varieties.

Among the carnations exhibited by Messrs. Young and Co., Hatherley, we made note of the new blush pink Hon. John Boscawen, Lady Audley Nield, Duchess of Devonshire, and Scarlet Glow. Mr. C. Engelmann, Saffron Walden, presented some excellent carnation blooms, and showed the yellow Sunstar and the pink Lady Northcliffe in very fine condition. Mr. H. Burnett brought over a beautiful lot of carnations from Guernsey, and delighted everyone with his vases of Lady Alington, Benora, White Chief, Mrs. C. F. Raphael, Rosette, Triumph, etc.

Mary Allwood was the outstanding carnation in a group of these popular flowers set up by Messrs. Allwood Bros., Haywards Heath, but Mrs. T. M. Cook, Rosette, Mrs. C. W. Ward, and the new and dainty rose-flaked Wivelsfield Wonder were also on view. A good strain of cyclamen with a bold group of carnation blooms, a batch of Acacia cordata, A. armata, and Erica melanthera made up a fairly large display from Messrs. Stuart Low and Co., Bush Hill Park, Enfield. Mikado, Salmon Enchantress, St. Nicholas, the new Northport, and White House, were the carnations chiefly shown in the small group set up by Messrs. Wells and Co., Merstham.

Forced flowering shrubs, chiefly azaleas, lilacs, and magnolias made up an effective exhibit from Messrs. Wm. Cutbush and Son, Highgate; at one end a fine set of carnation flowers were set up boldly, and notable sorts on view were Mrs. L. Mackinnon, Mrs. Tatham, King Manuel—a pretty cerise pink, R. F. Felton, and Countess of Onslow. A fragrant and elegant group of forced flowering shrubs from Mr. L. R. Russell, Richmond, was composed largely of standard lilacs and mollis azaleas, arranged over dwarf lilacs, pyruses, and azaleas.

A large contribution of ferns from Messrs. H. B. May and Sons, Edmonton, contained a batch of the exquisitely beautiful Nephrolepis Marshalli compacta, and grouplets of Gymnogramma schizophylla superba, the white powdered G. Mayi, the narrow-fronded Platycerium Cordreyi, and other good things.

Messrs. C. Brooks and Son, Basingstoke, showed their strains of Primula sinensis; the whole of the blooms were laid flat on black velvet in blocks of from 60 to 100 flowers. The varieties were Queen Mary, salmon-pink; Orange King, King George V., crimson scarlet; Giant Salmon, and Queen Alexandra, white. Very bright blue were the cinerarias shown by the London Flower Co., North Audley Street, W.; the varietal name, Bleu d'Azur, was a capital one, and the plants attracted a great deal of attention.

Mr. A. Shambrook, gardener to the Rev. H. Buckston, Sutton Hall, Sutton-on-the-Hill, Derby, is a first-rate grower of cyclamen, and on this occasion showed splendidly-flowered examples of his fringed variety, Mrs. Buckston, one of these carrying about seventy fine bright rose-pink flowers. Flowering peaches were delightfully displayed by Messrs. Wm. Paul and Son, Waltham Cross, and their group of Double White and Double Crimson, with the double almond, was a foretaste of early spring.

Forms of Primula cashmeriana and P. denticulata, showing great advances in sturdiness, size of bloom, and colour over the type, were exhibited finely by Mr. Maurice Prichard, Christchurch; some of the named sorts, especially Sir D. Morris and Rob Roy, were remarkable for their rich rose-purple colouring. Anemones, saxifrages and hardy heaths were included in the group. Messrs. Barr and Sons, Covent Garden, again arranged a little rock garden near the entrance and filled it prettily with groups of Saxifraga Elizabethæ, S. oppositifolia, Muscari azureum, Narcissus minimus, N. cyclaminens, N. bulbocodium, Crocus Malyi, C. Sieberi, Scilla sibirica alba, and many other dainty and beautiful spring flowers.

The rock garden arranged by Mr. C. Elliott, Six Hills, Stevenage, was prettily filled with groups of Morisia hypogæa, Iris reticulata, Saxifraga oppositifolia alba, S. Elizabethæ, S. Burseriana Gloria in grand form, and Gentiana acaulis. The Wargrave Plant Farm, Lim., The Arcade, Liverpool Street, put up a very pretty rockwork display, and in it set out charming little colonies of Iris reticulata, Saxifraga oppositifolia, Myosotis Ruth Fischer, Primula megasæfolia, hepaticas, and the white form of Scilla sibirica.

Alpine plants shown by Messrs. Whitelegg and Page, Chislehurst, were backed by forced daffodils. Morisia hypogæa, Houstonia serphyllifolia, Anemone pulsatilla, Iris reticulata, and Aubrietia Violet Queen. Messrs Thompson and Charman, Adam Street, Adelphi, presented primulas set in rock work, and a few small-growing shrubs, including pernettyas. In the small collection from the Guildford Hardy Plant Company, hardy heaths were conspicuous, and an outstanding plant was the pink-flowered Andromeda calyculata. Messrs. R. Tucker and Sons, George Street, Oxford Street, W., exhibited a little rock garden, with hardy heaths, primulas, and Saxifraga Burseriana grandiflora, and S. oppositifolia lotena, with quite large flowers.

Primula malacoides alba, Saxifraga Burseriana major, Lupinus argenteus, with elegant silvery leaves, Soldanella alpina, and Iris histrioides, were the features of the group from Messrs. Bees, Lim., Liverpool. A goodly group from Messrs. T. S. Ware, Lim., Feltham, contained colonies of Bletia hyacinthina, the showy Primula cashmeriana, P. denticulata alba, Cyclamen Atkinsi rubrum, saxifragas in numbers, and the sweetly-scented Epigæa repens.

Mr. G. Reuthe, Keston, again showed an interesting collection of hardy flowers that included saxifragas, hardy heaths, rhododendrons, camellias, scillas, iris, and species of crocus. Mr. G. W. Miller, Clarkson's Nurseries, Wisbech, was chiefly represented by hepaticas, coloured primroses, and primulas. Messrs. J. Piper and Son, Barnes, put up a very pretty little rock garden in one corner of the hall, and had fine breadths of Primula megasæfolia, Iris pumila lutea, Primula denticulata alba, hepaticas, blue primroses, Saxifraga oppositifolia, and S. Burseriana major. Retinospora tetragona aurea, planted on the highest part, was a very pretty and pigmy shrub.

Mr. James Box, Lindfield, submitted a bright exhibit of early flowers that was rich in hardy primulas and miniature shrubs, Daphne Blagayana being especially noticeable among the latter. Messrs. R. Wallace and Co., Colchester, had many interesting plants; Tulip Kaufmanniana, Iris bucharica, Narcissus triandrus albus, Lithospermum prostratum, and Anchusa myosotidiflora were a few of the choicest. Messrs. G. and A. Clark, Dover, presented coloured primroses, hardy cyclamens, irises, hardy heaths, and the glaucus junipers, set in a small rock garden. Retinospora filifera aurea, saxifragas in variety, and Primula denticulata were shown, with primroses and scillas, on rockwork, by the Burton Hardy Plant Nurseries, Christchurch.

One of the largest and also one of the boldest of the many groups exhibited was one composed of Poetaz daffodils grouped around and under conifers from Messrs. James Carter and Co., Raynes Park, S.W. Foremost among the varieties was Aspasia, a splendid pot plant, carrying from four to six fragrant white flowers on a stout stem. Irene, Elvira, Ideal, and Jaune à Merveille were other good varieties of this useful section, but Aspasia stood out conspicuously in this large, tastefully-arranged, grass-margined group.

Bulbs grown and flowered in ornamental bowls of fibre proved an interesting exhibit, and Messrs. R. H. Bath, Lim., Wisbech, demonstrated once more the value of this method of culture; the pans of golden crocuses attracted us as much as anything.

An exhibit of dainty daffodils from Mr. F. Herbert Chapman, Rotherside Gardens, Rye, was composed entirely of triandrus hybrids, nearly all of those staged being raised by Mr. Chapman. There were no fewer than fifty distinct sorts, and all were of refined form and habit. A few of the white sorts that attracted special attention were White Hart, Alabaster, Mrs. Walter Wright, Madonna, White Witch, and Problem. N. minacycla, the lemon-cupped Problem, and the dainty Little Bo-peep, as well as the bolder Bennett Poë, were other charming varieties.

Early daffodils were boldly shown by Messrs. Barr and Son, Covent Garden, their group being fronted by batches of Dutch crocuses. A few of the most striking daffodils were Primrose Queen, Blackwell, King Alfred, Blazing Star, Alice Knights, the bright golden Mikado, and White Lady. The tulips shown were also very good.

In a setting of Isolepis gracilis, Messrs. Cartwright and Goodwin, Kidderminster, set up a very bright and attractive contribution of cut daffodils, with a few hyacinths, muscaris, and a pan of the beautiful large white crocus named Kathleen Parlow (A.M.), a grand variety that has one faint line of rose-purple along the centre of each inner

segment. Among the daffodils Cornelia, Henry Irving, Victoria, Southern Star, Firebrand, and Blackwell were a few of conspicuous merit.

Paintings of flower and garden scenes were unusually numerous. Miss M. H. Mason, the lecturer of the afternoon, exhibited a large collection of sketches of landscapes of the Transvaal, and flowers of South, Central, and Eastern Africa, these latter drawn life-size from nature. Miss C. di Guardi, Montague Road, Richmond Road, Surrey; and Miss Adie, Brechin Place, W., were exhibitors of pictures. Miss Ivy Massee, Gateacre, Kew, sent skilful drawings of fungi, saxifragas, orchids, rhododendrons etc. Mrs. E. Fisher, Westerham, East Molesey, showed flower studies and views in Hampton Court Gardens. Miss Ough, Westwell Road, Streatham Common; Miss Josephine Gundry, Foot's Cray, Kent; Miss E. Warrington, Streatham Common; and Mrs. Macalister, Thurloe Square, W., were other artists whose productions were on view.

ORCHID COMMITTEE.

Mr. Alexander, orchid grower to Lieut.-Colonel Sir George Holford, Westonbirt, Tetbury, brought up Cymbidium Gottianum, the showy L_{a}-c. Valeria and Cattleya Leda (A.M.), a handsome Percivaliana cross, with deep rose-purple and gold flowers. Cymbidium Alexanderi Fowler's var. (F.C.C.) was very fine as shown by Mr. J. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford; this has rich rose-pink flowers of considerable size, and is one of the best of the C. insigne crosses. Mr. G. Day, gardener to H. S. Goodson, Esq., Fairlawn, Putney, put up a very pretty and interesting group, consisting chiefly of Odontioda Bradshawiæ Goodson's var., O. Keighleyensis, Odontoglossum ardentissimum, O. Loochristyense, O. Lambeauianum Henry Goodson, O. allium, and Phaius Norman. The plants were grouped pleasingly amid ferns and moss.

The large and brilliant Odontioda Mrs. F. M. Ogilvie, with pink, scarlet, and white colouring, was finely shown by Mr. Balmforth, gardener to F. Menteith Ogilvie, Esq., The Shrubbery, Oxford; the spike carried fourteen flowers. Odontoglossum Amethyst Glebelands var. (F.C.C.), a fine hybrid between O. eximium and O. Lambeauianum, was splendidly shown by Mr. J. Gurney Fowler, and its brilliant red-brown and rose-coloured flowers were a great attraction.

Cattleya Trianæ The Baron, with beautiful broad white petals and sepals and a blush yellow-throated lip, gained a F.C.C., as shown by Mr. Shill, gardener to Baron Bruno Schroder, The Dell, Egham; Odontoglossum crispum The Dell Sunrise, with a brown edge to the sepals, was another notable plant from The Dell.

Messrs. J. and A. McBean displayed fine plants of Cymbidium insigne with tall spikes of pink flowers; C. Schlegeli, C. Gottianum, Odontoglossum sceptrum, O. Lambeauianum, and other good things. Mr. Roberts, gardener to Miss Baker Baker, Ellemore Hall, Durham, showed the pale blush Bletia hyacinthina gebina. Mr. W. A. Manda, St. Albans, put up a group of orchids, consisting chiefly of varieties of Cattleya labiata. Mr. Maurice Mertens, Ledeberg, Ghent, exhibited Miltonia Bleuana nobilior, and a few bright hybrid odontoglossums and odontiodas.

Messrs. Sander and Sons, St. Albans, had a quite big display of orchids, including a brave show of Cattleya Trianæ, spikes of Odontoglossum elegans polyanthum, O. Pescatorei, with Cœlogyne flaccida, Odontioda Bradshawsiæ, Cypripedium Caractacus, Dendrochilum glumaceum, and some dendrobiums. Cattleya Trianæ Pallas, a pale blush form, was a charming form in this group.

From the Liverpool Orchid Nursery Company, Gateacre, Liverpool, came a small group of lælio-cattleyas of the Hippolyte section.

Messrs. J. Cypher and Sons, Cheltenham, put up some fine plants of good varieties of Lycaste Skinneri, spikes of Calanthe Bryan, the old Angræcum eburneum, and Phalænopsis Schillerianum, with good examples of Cypripedium Minos Youngi, C. Alcibiades superbum, etc. S. Gratrix, Esq., Whalley Range, Manchester, sent Odontoglossum crispum Leonard Perfect, a fine variety that had fourteen of its splendid, brown and red blotched flowers.

Exquisitely beautiful was Brasso-cattleya Menda (C. labiata Virginia × B.-c. Queen Alexandra), from Mr. Hunt, gardener to Pantia Ralli, Esq., Ashtead Park, Leatherhead. It has white sepals, greenish-white petals, a creamy lip with a purple line in front, and gained a F.C.C. Messrs. S. Low and Co., Enfield, had a goodly display of Dendrobium Wardianum, varieties of Cattleya Trianæ, Lælio-cattleya Bella, Cypripedium Mrs. Mostyn, Cœlogyne pandurata, and Brasso-cattleya Imperatrice de Russie.

FRUIT AND VEGETABLE COMMITTEE.

Especially fine in form and colour were the carrots, beet, turnips, and parsnips exhibited by Mr. Gentle, gardener to Mrs. E. H. Denison, Berkhamsted. Mr. Gentle is an adept at cultivating garden root crops, and seems to have a special lathe for his carrots and beet. His onions and potatoes were of equal merit, clean, well-kept, and really handsome.

Messrs. Sutton and Sons, Reading, had a few dozen lovely heads of their Superb Early White broccoli, an early self-protecting variety of great value, and high quality.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Cattleya Trianæ The Baron, from Baron Bruno Schroder (gardener, Mr. D. Shill), The Dell, Egham; Brasso-cattleya Menda, from Pantia Ralli, Esq. (gardener, Mr. Hunt), Ashtead Park, Leatherhead; to Brasso-cattleya Goodson's var., from H. S. Goodson, Esq. (gardener, Mr. Day), Putney; to Cymbidium Alexanderi Fowler's var., and to Odontoglossum Amethyst Glebelands var., from J. Gurney Fowler, Esq., Glebelands, South Woodford.

Award of Merit.—To Lælio-cattleya Leda, from Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury; and to Crocus Kathleen Parlow, from Messrs. Cartwright and Goodwin, Kidderminster.

Cultural Commendation.—To Mr. Kempshall, gardener to the Duchess of Ilchester, Abbotsbury, Dorset, for fine flowers of Magnolia Campbelli.

MEDALS.

Silver-gilt Flora.—To Messrs. J. Veitch and Sons, Chelsea, for azaleas, etc.

Silver-gilt Banksian.—To Mr. Burnett, Guernsey, for carnations; to Messrs. J. Hill and Son, Edmonton, for ferns; to Messrs. H. B. May and Sons, Edmonton, for ferns; to Messrs. Sutton and Sons, Reading, for primulas.

Silver Flora.—To Mr. Day, gardener to H. S. Goodson, Esq., Putney, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. Charlesworth and Co., Hayward's Heath, for orchids; to Messrs. Barr and Sons, Covent Garden, for daffodils, etc.; to Mr. F. Herbert Chapman, Rye, for hybrid daffodils; to Messrs. W. Cutbush and Son, Highgate, for carnations and flowering shrubs.

Silver Knightian.—To Mr. Gentle, gardener to Mrs. Denison, Little Gaddesden, Berkhamsted, for vegetables.

Silver Banksian.—To Messrs. Sutton and Sons, Reading, for broccoli; to Sir Walter Gilbey, Elsenham, for lavender water; to the Rev. H. Buckston, Derby, for cyclamens; to Messrs. Jas. Carter and Co., Raynes Park, for daffodils; to Mr. C. Elliott, Stevenage, for alpines; to Messrs. R. Gill and Son, Falmouth, for rhododendrons; to Messrs. Stuart Low and Co., Enfield, for carnations, etc.; to Messrs. Wm. Paul and Son, Waltham Cross, for flowering peaches; to Mr. L. R. Russell, Richmond, for forced flowering shrubs; to Messrs. Whitelegg and Page, Chislehurst, for hardy plants; to Messrs. W. A. Manda, St. Albans, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. J. and A. McBean, Cooksbridge, for orchids; and to the Liverpool Orchid Nurseries, Gateacre, for orchids.

Bronze Flora.—To Messrs. Allwood Bros., Hayward's Heath, for carnations; to Mr. G. Renthe, Keston, for hardy flowers; and to Messrs. T. S. Ware, Lim., Feltham, for hardy flowers.

Bronze Banksian.—To Mr. Maurice Prichard, Christchurch, for hardy flowers; to Messrs. J. Piper and Son, Barnes, for rock garden.

National Chrysanthemum Society.

A meeting of the Executive Committee was held at Carr's Restaurant, Strand, W.C., on Monday evening last, under the presidency of Mr. T. Bevan. Business was of a somewhat formal character. The retiring members of the Floral Committee were re-elected, and Mr. Martin Silsbury was elected to the one vacant seat. The finance, schedule, and publications sub-committees were reappointed, and Messrs. P. Cragg and W. Wells, jun., were added to the latter. A few new members were elected.

After this meeting the members of the Floral Committee dined together, Mr. D. B. Crane presiding. A pleasant evening was spent, the short speeches, many of an interestingly reminiscent character, being sandwiched between songs and readings.

National Dahlia Society.

During the evening of Friday, February 14, this society held its fourth annual conference at Carr's Restaurant, Strand. The President, Mr. George Gordon, V.M.H., opened the proceedings, and referred to the growing interest in dahlias, an interest that the conferences had doubtless deepened. The society was entering upon a new and vigorous policy, but it needed more support if it was to carry out its work properly and make the dahlia as popular as it deserved, and in this connection he urged that every member should do his utmost to secure new adherents. He said that three growers of the highest eminence were present to read papers, and had come from long distances to give their experience. Mr. Wyatt, of Salisbury, was well known as a raiser and grower; Mr. Treseder, from Cardiff, was known as an extensive and successful competitor, while Mr. A. Cobb came from Duffryn Gardens, where probably more dahlias were grown for garden decoration than in any other garden in the United Kingdom.

EXHIBITING AND JUDGING DAHLIAS.

The President then called upon Mr. Wyatt, and in passing we may say that Mr. Wyatt demonstrated many of the points raised during the reading of his paper, and showed how dahlia flowers might be made to look better on a show board than at present by raising the two back rows in tubes, and adding greenery beneath these raised rows. Mr. Wyatt's subject was "Dahlia Exhibiting and Dahlia Judging," and we hope to give his paper in extenso in an early issue.

Mr. J. Cheal opened the discussion with thanks to Mr. Wyatt. He was not prepared to follow Mr. Wyatt's suggestion that a dahlia was pre-eminently a show flower and its setting was of little value. Mr. Cheal maintained that the habit of a dahlia should count for a great deal, and would certainly add to the interest of dahlias as a class. He emphasised the need for extreme care on the part of the judges not to miss any stand in any class. Discussing the points laid down, Mr. Cheal said it was quite possible to give too great a value to size, and pointed out that refinement should receive full consideration. Setting up he also considered a matter of no small importance.

Mr. J. T. West put high quality far before size in the matter of show dahlias, and he thought the N.D.S. had sinned in this respect, the judges paying too much attention to size. He thought the use of foliage under the two back rows presented some difficulties, as such foliage flagged rather quickly.

Mr. J. B. Riding said that some dahlias had nothing but their face to recommend them, and he urged that good character—long and stiff stem, for instance—was of even greater importance than good looks. He was in general accord with Mr. Wyatt in his scale of pointing for judging, but said that far too much attention was given to size. There was, he said, a great need for a good code of judging for dahlias.

THE FUTURE OF THE DAHLIA.

Under this title Mr. Treseder peeped into the future, and, basing his observations upon recent history, he predicted a larger measure of support for garden dahlias, and suggested the possibility of new developments.

Mr. Cheal said Mr. Treseder's remarks were most inspiring and suggestive; it was difficult to discuss what had been said, but he would emphasise the need of an ideal in the minds of those who were raising dahlias, and strenuous effort to attain that ideal. In public gardens there was special need of the greater use of dahlias.

Mr. Riding believed there was a need for a sharper distinction between pæony and decorative dahlias; the latter were double, the former, though possibly having two or three rows of florets, must show a considerable centre, and be of more single character.

Mr. West humorously suggested pensions for dahlia raisers until the ideal dahlia could be raised, suitable alike for the show board and the garden.

Mr. Treseder, in reply, said he felt that show and garden dahlias would always be kept distinct from those desirable for garden effect.

GARDEN DAHLIAS.

Mr. Cobb then proceeded to read his paper on "The Selection and Cultivation of Dahlias for the Garden," and a portion of this is given in another part of the present issue.

After Mr. Cobb's instructive and enthusiastic paper, the President spoke of the need for a careful selection of varieties suitable for garden decoration, and also for a careful consideration of methods of culture when garden decoration was the point in view.

Mr. Treseder described briefly the dahlia garden at Duffryn, situated in a slight depression, with its hundreds of plants flowering profusely, and providing a glorious and startlingly impressive scene, that pointed very clearly to a great future for the dahlia. Mr. Riding and others joined in the discussion.

Mr. C. H. Curtis proposed a vote of thanks to the readers of papers, and suggested that a code of judging and a new set of "properties" would be a good outcome of the conference. He referred to the possible use of dahlia species for the creation of new races. Mr. Welsh seconded the motion, and said how eagerly the dahlia growers, particularly the smaller amateurs, looked forward to the publication of the papers read. He suggested a Certificate of Merit, by way of prize, for circulation among societies affiliated with the N.D.S.

This vote having been passed heartily, the President referred to a proposal from Mr. Cory to hold a trial of garden dahlias at Duffryn during the present year, and requesting help to make this trial as extensive and useful as possible. A vote of thanks to the President brought the proceedings to a close.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

Croydon Gardeners' Society.

A lecture of much interest and great practical importance was recently given before the members of this society by Mr. G. C. Gough, A.R.C.Sc., B.Sc., a scientist from the Board of Agriculture and Fisheries.

The subject of Mr. Gough's lecture was the American gooseberry mildew, a scheduled disease in gooseberry culture, and one which has given considerable trouble in parts of Kent and other counties. Being a scheduled disease, anyone finding it prevalent in their gooseberry plantations, must report it to the Board of Agriculture, under penalty of a fine for failing to do so. It necessarily follows that all cultivators should be acquainted of its habits so that they can easily recognise it. When first discovered the Board issued an order that all trees infected were to be grubbed up and burnt, but this order has since been rescinded, and the case has only to be reported, and the inspector from the local Council will examine the trees, and effective measures to combat the disease will be advised.

The lecturer explained that after carefully investigating the cause and effect of this disease it was found to belong to the mildews, and is quite different to any other form; especially must it be noted the difference between this and the European gooseberry mildew. By aid of lantern slides Mr. Gough gave illustrations of magnified spores of the two diseases, and their formation was thus readily made apparent to his audience. Where badly infected bushes are found traces may be discovered on currant bushes, but the character of the currant being somewhat different to the gooseberry it does not adapt itself so readily, and is easily eradicated. Strange as it may seem the good cultivator is more likely to suffer than the possessor of trees which are not so well cared for. This is accounted for by the tenderer growth on the well-cultivated trees. The parasitical nature of the mildew finds in the young succulent growth a better host than old and matured wood. It has its seasons of growth, and about April and May will be found in its earliest stages. A white mildew will be noticed about this time on the tender foliage and young growths. After a few weeks it changes to a yellow colour, and as the season advances it takes to itself a chocolate hue. Spreading to the fruit it quickly covers this and makes it unfit for use. When it has reached the chocolate colour it can be easily detected by scraping a little from the bark, from which it readily peels off. At this stage the difference can be noted from the brown appearance of the wood made with the green-fly ravages. If left through the winter the spores drop off to the soil underneath, and there remain for long periods. Spraying with sulphide of potassium is not much use, for the spore is coated with a hard substance, and this strong wash will not penetrate the skin. To combat the disease Mr. Gough advised cutting off all the tips of infected growth and all infected fruit, consigning both to the fire. This should be done by October 31 at the latest. This procedure will prevent the spores falling to the soil for its resting period. The use of nitrogenous manures is not to be recommended because of their favouring the development of succulent growth. A dressing of slaked lime on the surface soil applied in April will be beneficial.

A few exhibits were staged by members and greatly appreciated. Mr. W. Tyrrell showed half a dozen parsnips; Mr. A. Edward, hyacinths, tulips, and narcissus, growing in moss fibre; well-flowered sprays of Prunus Pissardi, showing the early season, were staged by Mr. F. W. Moore; and 29 tubers of Midlothian Early potatoes, comprising the yield from one tuber, were exhibited by Mr. H. Bridge.

NEW BOOKS.

AMATEUR GARDENING ANNUAL AND YEAR BOOK, 1913.

Edited by T. W. Sanders, F.L.S. (Messrs. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London, E.C.) Price 1s. net.

The new edition of this annual forms a work abounding in interest and of great practical value to amateur gardeners of all classes. A special feature is made of the work in the garden, greenhouse, and home during each month of the year, and deservedly so, for the article dealing with it is so arranged as to render immense assistance to its readers in carrying out the many details that require attention in the several departments. Each month is divided into two sections, one of which is devoted to the work that has to be done in southern gardens and the other to that which will require attention in the gardens of those resident in the northern counties. This arrangement is a considerable improvement upon that in which there is no differentiation in the requirements of southern and northern cultivators. In addition to this important feature there are special articles on various subjects, prominent among them being those on "Hardy and Half-hardy Annuals," "Planting of Hardy Herbaceous Borders," "Formation and Planting of Rockeries," and "How to Manage a Greenhouse."

The Annual is profusely illustrated, and the illustrations are throughout of so high an order of merit as to render it not less remarkable for its attractiveness than for its utility as a comprehensive guide to the garden.

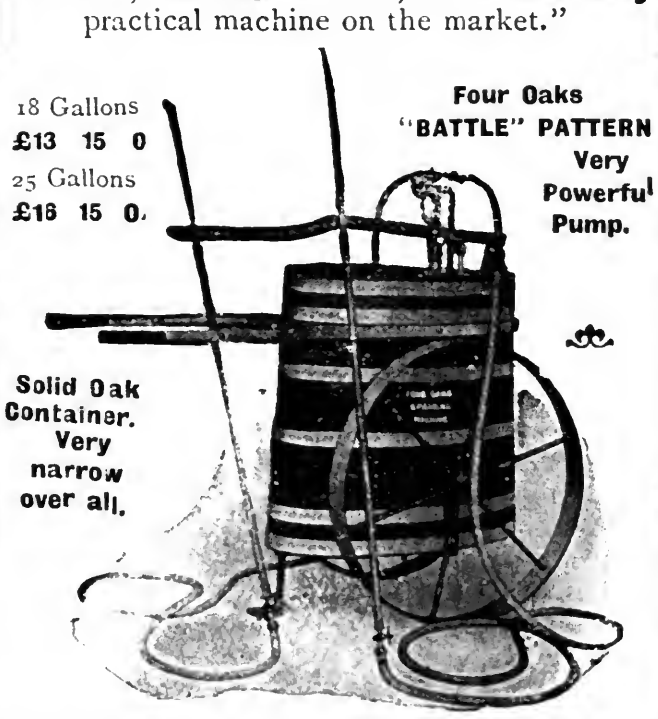
THE HORTICULTURAL DIRECTORY, 1913.

Journal of Horticulture," Essex Street, Strand, W.C. Price 1s.

The new edition of this work fully maintains the traditions which have become associated with it during the past fifty-four years, and should receive a welcome not less warm than in the previous years. So well known and highly appreciated are the merits of the publication that there is no occasion for us to write of it at length, or indulge in praise. Suffice to say that it amply fulfils its title, and, as a directory of all that relates to horticulture, is as complete and satisfactory as could be desired. Therefore it should be regarded as essential to all who are interested in the various horticultural activities.

Spraying.

One of England's leading Fruit Growers says: "I consider the 'Four Oaks' Spraying Machine, **'Battle'** Pattern, to be **the only** practical machine on the market."



Complete Catalogues of Spraying and Limewashing Machines and Syringes of every description free on application to the Sole Manufacturers:-**THE FOUR OAKS SPRAYING MACHINE CO., No. 3C, Sutton Coldfield.**

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

CŒLOGYNE CRISTATA.—C. W., Stockton: I have a few pans of Cœlogyne cristata, and the plants have flowered very freely. The roundish pseudo-bulbs fill the pans, and it seems that potting would be desirable. Would you advise potting; and, if so, when should the work be done?—When cœlogynes need repotting the work should be done quite soon after the flowers have faded, as new growth and new roots at once commence. C. cristata does not care for frequent root disturbance; therefore it should be so potted that there is room for development for a couple of seasons Where many plants are grown it is usual to pot half the number each year. Pans are preferable to pots, as C. cristata is of creeping habit, and is not deep rooting. Use live sphagnum and peat or osmunda fibre in about equal proportions with a little broken charcoal and sand. Ensure free drainage and press the compost firmly about the roots.

CHIVES.—B. M. B., Shrewsbury: What is the best time of year to move and replant chives? We have a very small patch, but the leaves were so much appreciated last year for flavouring that we propose to increase our stock if that is possible from what we have at present.—It is usual to increase the stock of chives by division of the clusters either in autumn or spring. You should lift and divide your plants directly weather permits, placing the bulbs six inches apart in rows a foot apart. A piece of fairly good ground should be chosen, but the plantation should be rather narrow, so that the leaves may be gathered from either side.

DIPLOMA IN HORTICULTURE. — W. B. M., Dorset: Appreciating the importance of gardeners doing all that is within their power to raise the status of the members of the gardening craft, I was very pleased to learn from the pages of the GARDENERS' MAGAZINE that the Royal Horticultural Society are about to take steps to confer the distinction of a National Diploma in Horticulture upon gardeners. As I should like to obtain the diploma I shall be much obliged by your informing me what I must do to qualify myself.—The scheme under which the diploma will be granted has not yet been prepared and published, but it will be granted on the results of an examination in the practice and science of horticulture. We have reason to believe that two examinations will have to be passed, the preliminary, the first of which will be held in 1914, and the final to be held about twelve months later. It is intended to hold the examination in three centres, and this will include written papers, viva voce questions, and practical work, the last-named to be done in a selected nursery. The examination will be open only to those who have had not less than seven years' experience in gardening. As you will readily understand, a thorough acquaintance with the practical work of the garden will be essential to success; and a full knowledge of botany, chemistry, entomology, fungology, and geology, in relation to the work of the garden, will, it may be assumed, be not less necessary. It will be well to wait until the syllabus is issued before preparing a systematic course of work, but you should at once proceed with the study of the several subjects mentioned. It may be well for you to enter for the ordinary examination in horticulture that will, as usual, be held by the Royal Horticultural Society this year, for not until you have passed that can you hope to pass the preliminary for the diploma. The ordinary examination will not only be useful in testing your knowledge, but the experience gained will give you greater confidence when you have to deal with more advanced questions.

LYCHNIS CHALCEDONICA.—A. M. E., Dorchester: I have been told that there are double-flowered varieties of Lychnis chalcedonica; please tell me if this is correct, and whether such double sorts are worth growing. —The well-known Lychnis chalcedonica, with its dense heads of scarlet blooms, is represented in gardens by at least two double forms, one scarlet and one white. These double varieties should be obtained, and planted at the end of March or in early April. They are not so robust as the type, but if planted in rich, loamy, and well-drained soil they will make good clumps provided they are left undisturbed for a couple of years. Propagation is by division in autumn or spring. These double forms are well worth growing, especially if you are interested in herbaceous plants.

MOLASSINE MEAL AND MANURE.—A correspondent, who has had a complete failure with mushrooms, although following methods previously successful, wishes to know whether the failure is in any degree due to the fact that the droppings used for the mushroom-bed were from horses fed with Molassine meal. We should say the failure is due to some other cause, but shall be very glad if any of our readers can enlighten our correspondent on this matter.

MUSA ENSETE FOR SUMMER EFFECT.—R. G. D., Tunbridge: We have had a root of Musa Ensete given us, and it seems as though two growths are likely to start therefrom. What is the best way to proceed with it for the purpose of securing good plants that will be effective in the garden during the summer?—You are probably fully aware of the means whereby cannas, started now, can be grown successfully; the culture of Musa Ensete may follow on similar lines. Afford moist heat and rich soil; if two growths start carefully separate them, and pot each separately. Allow plenty of room, feed liberally when the plants are growing freely in their final pots or tubs, and gradually harden off in May, so that plants may be put out of doors with safety early in June.

LAYERING OR RINGING FIGS.—A. B., Bradford.—I wish to take layers from a bush fig tree, by bringing branches through pots, my idea being to cut these from the parent bush below the pot, in the autumn. Kindly advise me how and where to cut the buried portion of the stem, to encourage rooting.—If a cut is made fairly deep in one side of the stem, to form a tongue, as in ordinary layering, and a piece of stone is placed so as to prevent the tongue from touching and growing on to the main portion, roots will be formed. The cut should be made at a point that will come rather more than half-way up the pot. Two tongue-like cuts, on opposite sides, one two inches below the other, would probably be an improvement. Write and tell us how many "layers" you make, and how many good plants result.

SPECIES OF ARAUCARIA.—P. G. H., Wigtown: Will you please tell me how many species of araucaria there are in cultivation? Discussing the matter the other day with a friend we could only think of three, i.e., A. excelsa, A. imbricata, and A. Bidwilli.—There are not very many species of araucaria, and beyond A. imbricata and A. excelsa, few are in cultivation outside botanic gardens, and special collections of coniferous trees. The chief species, all in cultivation at Kew, are A. Balansæ, from New Caledonia; A. Bidwilli, the Queensland "Bunya-Bunya"; A. brasiliana, from the mountains of Southern Brazil; A. Cooki, a New Caledonian species; A. Cunninghami, the Moreton Bay Pine, from Queensland; A. excelsa, the Norfolk Island Pine; A. imbricata, the popular Monkey Puzzle; and A. Rulei, from New Caledonia. There are a number of very distinct forms of A. excelsa, and several of these are of recent introduction.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well-marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

E. T., Wolverhampton.—1, Nuttalia cerasiformis; 2, Ruscus aculeatus; 3, Pinus Coulteri; 4, Saxifraga apiculata.

S. E. B., Norwich.—1, Odontoglossum triumphans; 2, Dendrobium Pierardi; 3, Phaius grandifolius; 4, Tillandsia Lindeni.

H. W. C., Chingford.—1, Prunus divaricata; 2, Sempervivum arachnoideum; 3, probably S. flagelliformis, send when in flower.

C. R., Chepstow: 1, Saxifraga sancta; 2, Adiantum tenerum; 3, Davallia polyantha; 4, Selaginella Mertensi variegata; 5, Garrya elliptica.

NEWS FROM HEADQUARTERS.

"THE BIG FOUR."

One's bank balance would rapidly vanish if the amount withdrawn were not periodically replenished.

That fact everyone recognises.

Yet how apt the amateur gardener is to forget that the same is true of sustenance for ever being steadily drawn from the soil by plant life!

The nourishment yielded by the soil is no more inexhaustible than the funds in one's bank. Unless the heavy withdrawals be periodically replaced we can expect nothing but weakly plants that fall easy prey to late frosts, prolonged droughts, blights, and disease. It is fruitless spending money on seeds and bulbs unless this elementary law of nature be obeyed.

There are FOUR BIG DEBTS we must pay back to the land in return for her bounty. These — "The Big Four" — are Lime, Phosphoric Acid, Nitrogen, and Potash.

Lime we place first and foremost because soil that is deficient in this element becomes sour, stagnant, and unresponsive to any other fertiliser. At least 90 per cent. of failures in cultivation, one eminent authority declares, is attributable to a deficiency of lime.

It is phosphoric acid that supplies the strength and stamina without which the plant cannot make its great effort in producing perfect fruit.

Nitrogen is responsible for the growth and foliage of the plant; when it is deficient the crops are backward, stunted, of yellow foliage, and quickly attract vermin.

Insufficient potash results in poor, hard, and tasteless fruit and vegetables.

A most interesting handbook on this important subject, "The Big Four," by Reginald Beale, F.L.S., will be sent free upon application. It deals lucidly and briefly with Soil Analysis for the amateur gardener, and with the various manures and fertilisers on the market.

CATALOGUES RECEIVED.

HERD BROTHERS, PENRITH.—A wide range of subjects is listed in this catalogue.

JOHN PEED AND SONS, WEST NORWOOD.—An extensive seed list, freely illustrated, and well arranged.

CHARLES TURNER, SLOUGH.—A larger catalogue than usual; flower seeds are especially well listed, and a feature is made of collections.

W. W. JOHNSON AND SON, BOSTON.—A concise retail list of vegetable and flower seeds; seed potatoes and sweet peas are leading features.

HARRISON AND SONS, LEICESTER.—The wholesale list of vegetable and flower seeds issued by this Midland firm is very interesting, and it is nicely illustrated.

C. ENGELMANN, SAFFRON WALDEN.—An illustrated price list of perpetual-flowering carnations; specimen blooms, vases of flowers, and houses of plants are depicted.

RYDER AND SON, LIM., ST. ALBANS.—A wonderful catalogue of seeds, all in penny packets, and ranging from mustard and cress to orchids. Over 9,000 kinds and varieties of seeds are listed.

ROBERT SYDENHAM, LIMITED, TENBY STREET, BIRMINGHAM.—A compact pocket catalogue of seeds, containing a severe selection of varieties of vegetables and flowers. A coloured plate of sweet peas is included.

W. DRUMMOND AND SONS, DAWSON STREET, DUBLIN.—Plants, bulbs for spring planting, as well as sundries, and an extended list of flower and vegetable seeds is included in this freely-illustrated catalogue.

SUTTON AND SONS, READING.—Under the title of "Farmers' Year Book and Graziers' Manual," the Reading firm has issued a most interesting catalogue of farm seeds. Root crops and grasses receive very special attention, and the illustrations are excellent.

DICKSON AND ROBINSON, MANCHESTER.—A catalogue without an introduction; in other words, it has no preface, but opens at "Peas," and follows on with a rare selection of flowers, fruits, and vegetables derivable from seeds. There are plenty of illustrations, and a select number of meritorious novelties are listed.

BARR and SONS, COVENT GARDEN.—It is a pleasure to peruse this catalogue because, by virtue of its alphabetical arrangement, everything can be found easily. Novelties and specialities, lists of popular English names of flowers, of sundries, and of gardening books are included, as well as cultural notes, and the whole book is of handy form and size.

COUGHS, COLDS,

ASTHMA, BRONCHITIS

nd all kindred ailments are speedily cured by

Dr. J. Collis Browne's

Chlorodyne

The RELIABLE FAMILY MEDICINE

In DIARRHŒA and other complaints of the Bowels Dr. J. COLLIS BROWNE'S Chlorodyne acts like a charm, and its soothing and restoring effects are equally marked in COUT, NEURALGIA, RHEUMATISM.

Purchasers should see that the name, Dr. J. Collis Browne, is on the stamp and refuse all substitutes.

Convincing Medical Testimony with each bottle.

Of all Chemists, 1/1½, 2 9, 4/6.

ALWAYS ASK FOR THE ORIGINAL AND ONLY CHLORODYNE—COLLIS BROWNE'S.

FORTHCOMING ENGAGEMENTS.

THURSDAY, February 20.—Linnean Society meets.

FRIDAY, February 28.—Beckenham Horticultural Society, Lecture.

TUESDAY, March 4.—Royal Horticultural Society: Narcissus Committee meets at 11.30; Fruit, Floral, and Orchid Committee at 12 o'clock; Lecture at 3 p.m. on "The Spring Flower Garden," by Mr. W. H. Divers, V.M.H.; Scientific Committee at 4 o'clock.

Royal Horticultural Society's Show of Forced Spring Bulbs—two days.

Horticultural Club, Monthly Dinner and Conversazione, at Hotel Windsor, 6 o'clock.

Scottish Horticultural Association.

WEDNESDAY, March 5.—Royal Horticultural Society's Show of Forced Spring Bulbs; second day.

THURSDAY, March 6.—Linnean Society Meeting.

MONDAY, March 10.—United Horticultural Benefit and Provident Society.

TUESDAY, March 11. Surbiton Spring Show.

WEDNESDAY, March 12.—Clevedon Spring Show.

North of England Horticultural Society's Spring Show, at Bradford.

THURSDAY, March 13.—Torquay Spring Show.

TUESDAY, March 18.—Royal Horticultural Society: Narcissus Committee meets at 11.30 a.m.; Fruit, Vegetable, and Floral Committees at 12 o'clock; Lecture at 3 p.m. on "The Romance of Weeds," by Mr. R. Lloyd Praeger, B.A.; Scientific Committee at 4 o'clock.

SATURDAY, March 29.—Paisley Spring Show.

VOL. LVI.—No. 3,096. SATURDAY, MARCH 1, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

"Garden" Varieties.

Although the publications of the British Pteridological Society, now extending through some nineteen years, and still more the articles contributed for a still longer period to these pages, have done much to enlighten the public with regard to the origin of the now innumerable beautiful varietal forms of our native ferns, we still find constantly cropping up the term "garden forms," as applied to them. Although this is better than the more ancient epithet of "monstrous," which implies that Nature had, as it were, made a mistake in creating them, it is still as erroneous and as misleading, and betrays as much ignorance of the real facts underlying their production. To deal with the term "monstrous" first of all we might quite as justifiably apply the term to all our most beautiful flowers, and fruits, and vegetation generally which do not conform to the strictly botanical specific forms of the wild plants. It is purely a question of degree of variation, and can only be justifiably applied to the innumerable instances where, for some reason or other, irregular deformation occurs, due sometimes to reversion, more or less partial as in the cases of the transformation of floral organs to the foliar forms from which they have been derived in the process of evolution, or by local interference with normal development, due to injury, insect influence, or other causes. Such properly "monstrous" departures from the normal are, however, as a rule, non-inheritable. They are not, as in the case of "sports" proper, part and parcel of a general change in the constitution of the organism, plant, or animal concerned, which change affects the seed or spore so that the new character appears regularly in the succeeding generations. There are exceptions, but they are very rare indeed. When, however, we find a thoroughbred variety or "sport," with its structure symmetrically altered throughout, so that it far exceeds the normal parent in beauty, and when the spores or seeds be sown, we acquire a generation showing precisely the same peculiarities, even though it be in different grades, it is surely a misnomer to apply the epithet "monstrous" thereto. When, however, as sometimes happens, a "sport" appears in which persistent structural defects occur so that, instead of a more beautiful plant, we obtain a persistently ugly and imperfect one, then, indeed, we may apply the term with justice, but only then. Coming now to the so-called "garden" varieties, under which category the choice ferns are erroneously classed, the "garden" has nothing whatever to do with their origin, nor has it acted in any way as an incentive to the production of the beauty we see, since quite probably it may have been found in even greater beauty, in the wild glen, wood, or other unsophisticated habitat in which it was originally discovered as a purely wild plant of Nature's unassisted production. True it is that, subsequent to its discovery, its spores may have been sown, and new generations been raised of even greater beauty, and that, instead of the original wild parent, we may be viewing in the garden one of the many of its descendants, but this makes no difference at all. In that wild plant, and under wild conditions, the potency was implanted of producing these subsequent wider developments, the garden itself has not, and does not, contribute anything thereto, though, of course, we have to thank the gardener, the selective cultivator, for his care in sowing and selecting. Even he, however, can do no more than profit by the "wild" potency alluded to; and the result which it affords him the capacity of obtaining. These considerations, therefore, show us that it is only in the case of hybrids and crosses specially effected by the cultivator that the term "garden form" is in any way properly applied, since the results attained are due to human interference with normal reproduction, and would not, and perhaps, could not, have been acquired without it. With the wild "sports," however, it had been practically proved that, if left in their original habitats, their scattered spores may produce improved types without any human aid whatever. The mere growth within the limits of a garden, might just as well justify the appellation of "garden" forms to the millions of normals grown under the same conditions, which would obviously be absurd.

MR. GEORGE P. MILN, J.P.

Mr. George Peddie Miln, J.P., recently appointed a magistrate for the city of Chester, is widely known in commercial circles by reason of his long connection with Messrs. Dicksons, Lim., of Chester and his present position as managing director of Messrs. Gartons, Lim., of Warrington. He has devoted his attention chiefly to seed production, and has achieved considerable success in the improvement of cereals and grasses by cross-fertilisation and selection. Natural science has always claimed his devotion, but botany has been his particular hobby, and the Order Gramineæ his special study for many years. For a long period he was hon. secretary of the Chester Natural Science Society, and held the office of president for three years, and in this connection he was awarded the Charles Kingsley Memorial Medal in 1905 "for having contributed to some branch or department of natural science." He has been instrumental in establishing prizes for Nature study for the scholars of the city and district, and by his energy and influence he

has made the Chester Paxton Society a great power for good in the directions of practical and scientific horticulture. As hon. secretary and treasurer of this society he has come prominently before the gardeners, amateur and professional, of Chester and he is greatly loved and admired for his work's sake, so much so that in 1908 the Paxton Society pleasingly recognised his valuable services by presenting him with its gold medal. To the Bench of magistrates at Chester Mr. Miln will prove a wise and welcome addition, and he is to be congratulated upon the honour conferred upon him.

Research Work in Forest Products.—A paper on the development of research work in forest products will be read by Mr. E. Russell Burdon, M.A., Investigator in Timber, Forestry School, Cambridge, at the meeting of the Royal Society of Arts on Wednesday next, March 5, commencing at eight p.m. Lieut.-Col. Sir David Prain, C.M.G., F.R.S., V.M.H., will preside.

Kew Tea Pavilion Destroyed by Fire.—Shortly after 3 a.m. on Thursday, February 20, the popular Tea Pavilion at the Royal Gardens, Kew, was found to be on fire, and, though the local and Richmond fire brigades were soon on the spot, it was impossible to save the building, and very soon all that remained of the rustic creeper-clad tea house was a few erect, charred posts, and a heap of ashes. The fire is believed to be the work of militant supporters of woman's suffrage. Two women discovered running across the Old Deer Park at the Richmond end of the Gardens were captured, and in a bag thrown away by one of them tow and paper covered with tar were found. These women were charged at Richmond with setting fire to the building, and were remanded in custody, but we understand one has since been released because of ill-health. The Tea Pavilion is closed during the winter months, and had been opened the previous Sunday afternoon for the first time this year. The total damage done is estimated at about £1,000. The Pavilion is public property, i.e., it is part of the establishment, but it contained a large amount of material belonging to the caterers. Besides the loss of Government and caterer's property, there is the loss sustained by the waitresses thrown out of employment, a loss which probably did not occur to those responsible for it.

Horticultural Club.—The monthly house dinner will take place at the Hotel Windsor, Victoria Street, Westminster, on Tuesday next, March 4, at 6.30 p.m., when Mr. Edward A. Bunyard will talk about "The Introduction and Development of Some of Our Hardy Fruits," illustrating his remarks with lantern slides.

Pruning and Planting Fruit Trees.—In a lecture given at the Royal Institution on the 21st ult., Mr. Spencer Pickering, F.R.S., stated that the investigations at the Woburn Experimental Fruit Farm showed that the well-being of a tree depended on the balance between roots and branches, both of which supplied certain, but different, elements necessary for growth. It did not matter at what period of the year the annual pruning of a tree took place, so long as it was not done while the tree was in actual growth. A good deal could be said, however, as to the extent of the pruning, but it was established as a fundamental principle that the less pruning there was the more would a tree grow, and the more fruit would it bear. With regard to planting fruit trees when received from the nursery, Mr. Pickering said it could make little or no difference to the future welfare of the tree whether the ends of the old roots were trimmed, or left jagged and torn, nor whether these roots were carefully spread out, instead of being huddled into the hole prepared for them; for it was the new rootlets which were to be formed, and not the old ones, on which the future life of the tree depended. Even when the roots were twisted and tied together in a bundle the tree did just as well as when they were spread out in accordance with the general practice. All the anomalous results which had been obtained on the subject of planting were easily explained by, and were the material consequences of, the fact that a tree when transplanted had to form a new root system before it could begin to grow again, and if this were but kept in view the whole subject became simplified, and the reason became evident why many of the practices supposed to be essential to the proper planting of a tree did not bear the test of actual experiment.

Adviser in Forestry at Cambridge. — Mr. C. Hankin, forester to Earl Cadogan, has been appointed adviser in forestry to the Cambridge University. He will be associated with the Reader in Forestry, under whose responsibility all working plans and proposals of a general nature will be issued.

Kew Bulletin.—The recent issue of this publication is of quite exceptional interest. The more important of the contributions to its pages are the "Notes on some Species of Acalypha," which occupy twenty-seven pages, the descriptions of new orchids, and a communication from Mr. J. B. Davy, the Government Botanist of South Africa relating to "Teff" (Eragrostis abysinica), a grass which has proved of much value as a fodder plant. Seed of teff was obtained from Abysinnia in 1886 by the Royal Botanic Gardens, Kew, and was distributed to the botanic gardens and some other institutions in India and the Colonies. This grass is of annual duration, attains a height ranging from two to four feet, and makes so rapid a growth as to mature in seven or eight weeks. Its drought-resisting properties, combined with high nutritive value, have rendered it especially useful in South Africa.

The Kew Guild Journal for 1913 has just reached us. It is the twentieth issue. How time flies! It is full of interest to Old Kewites, and, indeed, of great interest to other horticulturists who know and appreciate the work of Kew and of Kew men the world over. The frontispiece is a fine portrait of Mr. William Goldring, an old Kewite famous in three-quarters of the globe as a landscape gardener. As usual, the Kew notes and the letters from Kew men in distant lands are excellent and entertaining reading, as well as descriptive and instructive; the letters are from Papua, Portugese East Africa, Philadelphia, Singapore, St. Vincent, Kuala Lumpur, etc. The list at the end of the "Journal," showing the geographical distribution of Old Kewites and the positions they occupy, is at once an "eye-opener" and a fine record that any institution might be proud of.

Spread of American Gooseberry Mildew in Kent.—A report on the extension of the American Gooseberry Mildew in Kent was presented to the County Council at its meeting on the 19th ult. by the Diseases Committee. The report states that there is now a total infected area of 3,353 acres, and that the unsatisfactory feature with regard to this disease is the great difficulty which the inspectors have in inducing growers to comply with their notices requiring them to cut out the diseased shoots within a prescribed time. Many of these notices expired on October 31 last, it being important that the work should be done early so that the ground would not become reinfected by the falling spores. At the date, however, of the inspector's report (January 14) the work on no less than 1,586 acres was still unfinished, plantations of that extent being still in a condition which could not be passed as satisfactory. The Board of Agriculture is considering whether they should not themselves take action in some of these cases, and has asked that the local inspectors may, if necessary, be allowed to assist the Board with their evidence. To this the committee have assented.

Mr. Augustine Henry, who has during the past six years occupied the position of Reader of Forestry at the Cambridge University, has been appointed Professor of Forestry in the Royal College of Science, Dublin. Mr. Henry is the first Professor of Forestry at the College.

Additions to the Kew Arboretum.—As has been the case now for some years past, the most noteworthy additions to the hardy ligneous collections during 1912 have been of Chinese origin. These, we learn from the "Kew Bulletin," have been presented by the Arnold Arboretum, Mr. J. C. Williams of Caerhays, Messrs. Veitch, Mr. Maurice L. de Vilmorin, and the Hon. Vicary Gibbs. Most of the plants are still under number, and to those of Mr. Wilson's collecting are now being added the results of the journeys of Messrs. Purdom and Forrest. Mr. Forrest is still in, or on the borders of, China. A very charming dwarf rhododendron of his introduction, R. fastigiatum, Franchet, flowered during the year; a species resembling R. intricatum in leaf and in colour of flower but very distinct in the long exserted stamens. It is interesting to note that both at Kew and with Mr. J. C. Williams it flowered when only a few inches high and within seventeen months of sowing the seed—a remarkably short period compared with that taken by most seedling rhododendrons. From Canon Ellacombe have been received several plants of great interest, especially old-fashioned roses of which he has so fine a collection. The Earl of Ducie sent seeds of Fagus obliqua, which germinated well, and various plants have been received from Miss Ellen Willmott, Sir John Ross of Bladensburg, and Lady Hanbury, La Mortola.

Border Carnations.—In our issue of the 8th inst. we shall make a special feature of border carnations, and the articles on these fragrant flowers will chiefly have reference to spring planting and other cultural details requiring attention at this season of the year. Illustrations will be given of several of the finest varieties of recent introduction.

Visit of the Gardeners' Company to Belgium.—In our issue of February 22 we stated that the Gardeners' Company had decided to make a visit to Belgium in the course of next summer. We now learn from the "City Press" that the members of the Company taking part in the visit will leave London on June 2 and return on June 9. In addition to the study of horticulture, the members will take an official part in the International Agricultural Congress at Ghent. The secretary of the Board of Agriculture and the head of the agricultural branch of that authority are to be invited to accompany the deputation as guests of the Company. The itinerary will include an inspection of the nurseries of Messrs. Sander and Sons, at Bruges, the School of Arboriculture near Bruges, the vines at Hoeyleart, the private gardens of M. Firmin Lambeau and M. Dietrich, the School of Horticulture at

Vilverde, the gardens at Malines, the orchid houses of M. C. Vuylesteke, and the nurseries of MM. De Smet freres, near Ghent. The World's Fair at Ghent will also be visited. It is expected that the deputation, M. F. Lambeau, and M. Dietrich, the School of Horticulture, and the delegates attending the Agricultural Congress will be among the company invited to a reception by the King of the Belgians at his Palace at Laeken.

Jobbing Gardeners' Wages at Edinburgh.—At a meeting of employers in the nursery, garden, and florist trade, recently held at the Lauriston Hall, Edinburgh, it was unanimously resolved to increase the charges for jobbing gardeners. The principal speaker at the meeting said that, not only were the charges, so far as the employer was concerned, too small, but the employees were much underpaid. After some discussion, it was unanimously resolved, on the motion of the Chairman, to fix the jobbing rates, as from March 31, at 8d. per hour to the master and a minimum wage of 6d. per hour to the employee. It was also decided to form a trade association to be called The Edinburgh and Suburbs Nurserymen, Gardeners' and Florists' Association.

Concert for the Gardeners' Royal Benevolent Institution.—The Committee of the Liverpool Auxiliary of the Gardeners' Royal Benevolent Institution has arranged for their annual smoking concert in aid of the funds of the Institution to take place on March 8, at the Bear's Paw, Liverpool. Mr. R. G. Waterman, Woolton, is the hon. secretary.

Protecting Young Conifers from Frost.—In the issue of the "Transactions" of the Royal Scottish Arboricultural Society reference is made to the utility of alders and birches in protecting young coniferous trees from frost. The alder grows rapidly, and the side branches afford protection to the conifers from frost in winter and the scorching rays of the sun in summer; this benefit is proved by the healthy, dark-green appearance of the young trees, and by the rapid growth which they make after they are once fairly established. Mention is made of the results obtained on a plantation where spruce and larch are mixed with hardwoods, on the outside of the plot, while the wet, low-lying centre of the plot is planted with spruce mixed with alder. The alders are about 12ft. apart, and have proved a splendid protection, for a frost at the end of April, which scorched dozens of spruce on the outside of the wood, left unharmed the trees mixed with alder.

Cottage Gardening in Scotland.—In order to promote an interest in practical cottage gardening, the Board of Agriculture is appealing to the teachers in the rural parts of Scotland to help in this matter. The Board is now prepared to supply free of charge for use in the teacher's garden a collection of flower and vegetable seeds, bulbs, herbaceous plants, trees, bushes, etc., to the value of £1, on condition (1) that the older pupils in the school receive practical instruction in gardening from the plots and be encouraged to apply such instruction at their own homes; and (2) that the condition of the plots, etc., and the pupils' progress in gardening be, if practicable, subject to such tests or reports as the Education Department may require. The Board of Agriculture will welcome at the end of the session a short report by the teacher showing the effect of the instruction on the home circumstances of the pupils. The officials of the North and West of Scotland Colleges of Agriculture are desirous of assisting in the development of school gardening in Scotland, and are prepared to advise as to the formation of school gardens, and, on invitation, will give personal assistance with the work.

The "Perfect" Lady Gardener.—A short time since the daily Press gave a great deal of attention to Miss Elsie Scheel, of Brooklyn, describing her as the perfect woman, because her bodily measurements were considered to be in perfect proportion. What we were not told was that Miss Scheel is a horticultural student at Cornell University. We rather expected to find the "perfect woman" was a lady gardener, and we understand she is taking the horticultural course at Cornell, so that presently she may assist her father, who has a farm at Long Island.

Spraying Potatoes.—In the two reports recently published by the Agricultural College, Bangor, some interesting particulars are given of the results obtained in the use of Bordeaux mixture as a preventive of potato disease. It is stated that the Bordeaux mixture, with which the potato crop was dressed, was prepared with 24lb. sulphate of copper and 30lb. pure washing soda dissolved in 120 gallons of water, per acre, and this was applied to two plots in the first half of July. To one of them a second application was made, and another plot was sprayed in the second half of the month, the object being to compare the effects of early and late spraying, and double spraying with single applications. The results last year did not differ materially from those of the four preceding seasons. The yield of marketable potatoes was not much more than half that in 1911, but the relative returns from the sprayed plots, as compared with the unsprayed plots, were about the same. The evidence of the five years shows that there was a gain of nearly one ton per acre from early spraying, of nearly two tons from two dressings, and of nearly 1½ tons from late spraying.

Mutation of Œnotheras.—At a recent meeting of the Linnean Society Dr. R. R. Gates called attention to mutating œnotheras, and referred to the following facts and views relating to mutation as an evolutionary factor: (1) Œnothera Lamarckiana has probably undergone crossing in the wild state to the same extent as other open pollinated species intercross. (2) The mutation phenomena are evidence of germinal instability resulting from crossing, change of climate, or cultivation. (3) Hybrid splitting is inadequate to account for the forms which suddenly appear. (4) Some of the mutants differ from the parent in their physiological adjustments, and this may account for cases of "climatic adaptation." (5) O. rubricalyx has originated as a heterozygous mutant, but there are obvious difficulties in applying the same explanation to the other mutants of the genus. (6) The origin of certain of the mutations, at least (e.g., O. lata, O. gigas), is intimately concerned with chromosome mechanisms; that of certain others may be concerned with the action of releasing stimuli. (7) Darwinian natural selection always assumed an original environmental change for the organism, either (a) a change of climate in a given area, or (b) the introduction of new organisms, leading to the gradual modification of the species. (8) But neither chance-wise mutations in all directions, nor the vicissitudes of changing climates and distributions can account for the orderly phylogenies which larger groups of organisms frequently show. (9) There is no single evolutionary factor, but the process is a multifarious one.

FINE FOLIAGED BEDDING PLANTS FROM SEED.

It is not to a special class of plants that this article is directed, but to those that possess leaves of a beautiful or attractive nature, and may be considered suitable for bedding purposes. Within the last few years many subjects have been introduced to this class of decorative planting, and by their use the beauties of our gardens and parks have been very considerably enhanced.

As there are very many plants that cannot find a place in the space at disposal, it is intended to give a brief list only of those kinds that are easily raised from seeds, and a place for which may be found in most gardens, great or small.

Among plants with grey or light-coloured foliage, the centaureas and cinerarias take a foremost place. These always give a softening touch, and help tone down other plants of brighter hues and colours. Centaurea candidissima, C. gymnocarpa, Cineraria, acanthifolia, and C. maritima are invaluable for bedding purposes. Seeds of these may be sown any time during February or early March in gentle heat, and the plants kept growing steadily until required in May or June.

Cannas and ricinus, in their respective varieties, are attractive, and very effective where a bold display of foliage is desired. Seeds of the former should be sown during January or February in brisk heat, and by generous treatment large and useful plants may be secured by the end of May or the early part of June. These plants may be used year after year, if the roots are stored safe from frost during the winter months. The Castor Oils (Ricinus), on the other hand, should be sown annually, or, as is the method of some, the seed may be sown in the autumn, and the plants wintered in a warm greenhouse, afterwards growing them in gentle heat in the spring.

Chilian or Brazilian beet are excellent subjects for a dry border, and grown under such conditions the colouring of the foliage is superb. These plants will not, however, stand much disturbance at the roots; it is therefore better to sow two or three seeds in a three-inch pot, finally thinning them down to one plant only; as the seedlings strengthen they may be potted on into larger pots, and by these means fine specimens are obtained by bedding-out time. Seed may be sown any time during March or April, as the plants make rapid growth in a temperature of 55 or 60 degrees.

Cannabis gigantea (Giant Hemp) is now too seldom seen, but is an excellent subject for use in sub-tropical bedding. The seeds should be sown in gentle heat some time in March; these quickly germinate, and the seedlings make rapid progress. Fine specimens are easily obtained by bedding-out time by potting the plants as they need it. The growths may be stopped from time to time, to induce the formation of miniature bushes, but, given a good strain, the seedlings seldom require such attention. Select, if possible, a sunny position, well-manured ground, and afford plenty of moisture at the roots; given these the plants soon attain to a height of six or eight feet.

Kochia tricophylla (Mock Cypress) is an exceedingly pretty plant, with light green, feathery foliage, which, as the season advances, gradually changes to a brilliant crimson hue. Seeds may be sown in March in gentle heat, and afterwards the seedlings may be grown sturdily in a temperature of 55 to 60 degrees. No kind of coddling must be attempted, as the plant resents any such treatment, but at all times

ample drainage must be given, and plenty of moisture at the roots. The kochias when fully grown, form neat, compact, pyramid-shaped bushes, from two to three feet in height. As dot plants for small beds they are admirable.

Given a warm soil, a sunny position, and well-drained beds or borders, Amaranthus superbus and A. tricolor splendens may be safely used as bedding plants. From a decorative point of view these are equal to many fine-foliage hothouse subjects. Used as dot plants over a suitable groundwork, such as lobelia, dwarf ageratum, or Cineraria maritima, the effect produced is very pleasing. Sow the seeds in heat during March, pot the seedlings as required, giving greenhouse or warm frame treatment until planting out time.

This brief list of foliage plants would be incomplete without including the ever-useful Zea gracillima variegata. Given a good strain of this variety, for general usefulness and effect it is hard to beat. Given the same treatment as the amaranthus excellent plants are obtained by the end of May. A sheltered sunny position—such as a sunk garden—free from rough winds, suits it best, for if unduly exposed the foliage suffers, and becomes unsightly. Zea quadricolor perfecta is also a desirable variety, the foliage being beautifully striped with purple, rose, and yellow. Both these varieties of maize grow to a height of three to four feet only.

W. Hedley Warren.

ROYAL HORTICULTURAL SOCIETY'S CHELSEA SHOW.

References have recently appeared in the Press indicating the disappointment felt in the City that the Royal Horticultural Society's "Great Spring Show," or, as it is better known in the City, the "Temple Show," is no longer to be held at the Temple, but in the Royal Hospital Gardens, Chelsea, where it will occur for the first time on May 20 to 22 next.

The Council fully appreciate this disappointment, and sympathise with it; nor was it without long and careful consideration that they could bring themselves to consent to the change. As pointed out in their annual report, "the society has received much kindness from the Master and Benchers in being allowed for so long a time to make use of their gardens, but for several years past the feelings of attachment to the Temple Garden and dislike of the overcrowding have been struggling together for the mastery. . . . The Council have unavoidably come to the conclusion that it is their bounden duty, in the interest of the vast majority of Fellows, to move the show in future to Chelsea, which affords a space nearly three times as large as the Temple."

The change having thus not been sought by us (far from it), but forced upon us by the intolerable crowding, the Council of the society hope that all fair-minded men in the City will fall in with the inevitable and unavoidable change which, after all, is only an outward expression of the splendid work being done by the society and of its progress. Even at this early date, we can promise a show which will far exceed any of the society's previous shows, and repay even busy City men for the very few additional minutes taken by the journey to Chelsea.

The Council have also, in response to the suggestion of a City banker, decided to keep their fortnightly shows at Vincent Square open one hour later than hitherto, thus clearly showing that they are by no means unmindful of the interest of those of their Fellows whose daily work lies in the City. The alteration cannot, unfortunately, be brought into action this year, as all notices, etc., have, some time since, been printed and circulated, but it is ordered to begin in January of next year. W. Wilks.

SELECT PEAS OF MEDIUM HEIGHT.

In a large number of gardens, especially those of medium size, and where tall sticks are not easily obtained the varieties of garden peas of medium height are generally preferred to the taller ones. At the same time it must not be supposed that these are equal, in many instances, to some of our best-known tall varieties, either for appearance or productiveness.

As is generally known, much attention has been paid during recent years to the improvement of these highly-esteemed vegetables in relation to quality and earliness, and, indeed, for maintaining an unlimited supply till quite late autumn.

Unfortunately, the numbers of names in catalogues are most puzzling, especially to those who are not fully acquainted with the relative merits of varieties, and, in my opinion, it would be a great gain if these varieties were reduced considerably. Very many cultivators feel that they are bound to grow old varieties, and others are inclined to those which generally do well in their various districts. There is, of course, a great deal to be said for this inclination, but there are a certain number of sorts which seldom fail to produce the best results in any locality, providing, of course, good cultural skill is brought to bear upon them. For some years past I have advocated dispensing with the old white-seeded varieties. These are so inferior in every respect to the late additions of the marrowfat type, and at the most are only a day or two earlier, that they are hardly worth the expense and trouble of cultivating.

To ensure gathering at the earliest possible moment I strongly advise sowing the early and second early varieties thinly in boxes, and raising them under glass in a low temperature, either in unheated houses or pits, or even in cold frames. Though this may appear to involve additional work and trouble, it is really not the case, and much better results are sure to follow. The seeds germinate much more freely under glass than they would do in the cold ground in early spring, and one has them under better control, and can more readily protect them from inclement weather, and the ravages of the various pests, such as rats, mice, slugs, and birds.

Peas ought not to be coddled, but should have a free circulation of air about them on all favourable occasions, and, after being properly hardened, may be planted out in a warm sunny position during favourable weather.

At the time of planting the supports should be added, and there is nothing better than good bushy hazel sticks, generally prepared for the purpose. Where birds abound some means should be taken to prevent these injuring the young growths. If carefully and firmly planted on well-prepared ground, the plants will be found to progress much more rapidly than those sown in the open, and will come into bearing much more quickly. Capital varieties for this purpose are Gradus, Early Morn, Early Giant, and Edwin Beckett. Each of these varieties will rise to a height of from three to four feet, according to the season and the condition of the ground. It is a common mistake to sow and plant these varieties, as, indeed, all kinds of peas, too thickly. Five or six seeds are frequently sown where one would suffice, the result being poor quality and the bearing season much shortened.

Sutton's World Record is unquestionably a very fine pea, absolutely distinct, and the flavour all that can be desired. This variety seldom exceeds three feet in height; an ideal pea for very small gardens. Thomas Laxton is another grand variety of superb quality, and generally succeeds well in any locality; height, three feet. For successional crops King Edward can be strongly recommended, and is one of the best varieties with which I am acquainted; the quality is of the highest, and the height from two and a-half to three feet. Triumph is certainly a good pea, averaging about 3ft., and very prolific. The Gladstone is much cultivated in the North, and is a very fine variety for exhibition; height, four feet. Unfortunately this does not succeed in all districts.

Veitch's Perfection is an old, but very reliable variety, and succeeds well in most gardens. The height is from three feet to three feet six inches. Autocrat, in my opinion, is one of the finest peas ever raised for producing late supplies. It is of first-rate quality, pods fill well, has a most robust constitution, and unless overcrowded seldom becomes affected by mildew. It is possible in many districts, unless exceptionally severe weather intervenes, to gather from this variety until quite the end of November. Masterpiece is no doubt a selection from the above, and a very fine one too. The pods are slightly larger, but otherwise it is much the same as Autocrat. I have grown this for many years, and can testify to its good qualities. The above two varieties will rise to a height of from four to four and a-half feet.

For midseason and later supplies too much care can hardly be taken in the preparation of the ground. The labour of preparing trenches much in the same way as is practised for celery will be well repaid. When the trenches are made fill them with good well-decayed manure. Peas always enjoy a good root run and also an abundance of moisture when in full growth. Both clear water and liquid manure should be liberally applied during periods of drought, as this does much to ward off the attacks of mildew. At the same time apply a good mulching of short stable litter to check evaporation. It is a capital plan, both for early and very late sowings, to pinch out the points of the leading growths, and remove all side growths after a fair crop of pods have set. It is surprising what an influence this has on the development of the pods.

Edwin Beckett, V.M.H.
Aldenham House Gardens.

An Interesting Competition was arranged by the Cardiff Gardeners' Association during the current session, and the results were made known at the recent monthly meeting. Prizes were offered for skill in pruning, and for papers on the cultivation of violets for winter flowering. Mr. H. C. Davies, Palace Gardens, Landaff, obtained the premier award in the pruning competition, and Mr. C. H. Oldham, Roath Park, was first in the contest for the prizes for papers on violets.

Birmingham Horticultural Society will hold its second annual exhibition in Handsworth Park on Friday and Saturday, July 18 and 19. The schedule of prizes is now ready, and may be obtained from Mr. W. Carradine, the secretary, Hamstead Road, Birmingham. Cash and trophies, to the value of over £600, are offered as prizes in a series of a hundred and eighty classes. Of special interest are the classes for groups, a rock garden, a floral hanging basket, table decorations, fruit, sweet peas, and the series of trade displays.

ANNUALS IN THE FLOWER GARDEN.

There has been such rapid improvement in the various flowering plants which are annually raised from seeds, that it is now almost possible to dispense entirely with the plants that one had to rely upon a few years ago for carrying out schemes of floral decoration in the flower garden.

It is not prudent nor desirable to entirely do away with these old-fashioned bedding subjects, but, by making proper use of annuals in positions which are really suitable for them, a great deal more variety may be introduced into the general scheme of garden decoration. There are, of course, many annuals which cannot be employed in prominent positions, as their flowering season is so short. These should be relegated to mixed borders in the kitchen garden, or vacant places in shrubberies. Those selected for filling beds in the immediate vicinity of the dwelling should flower during the greater part of the season.

Among the most useful flowers for this purpose are the antirrhinums. They are not really annuals, but are best so treated. To make the best use of these the seed should be sown in heat in February or early in March. When the seedlings are large enough, they should be pricked out into boxes. While in boxes they must not be allowed to become crowded or starved, and should the beds which they are intended to furnish be occupied with spring-flowering plants they should be again transplanted in the reserve garden. Here they will make strong plants, and be capable, when transferred to their summer quarters, of flowering all through the season. The intermediate class is generally the most useful, although in filling large beds with mixed colours both the tall and Tom Thumb kinds may be intermixed with admirable effect.

The annual delphiniums are also invaluable for massing in beds, and need similar treatment to that recommended for antirrhinums. Lavateras are excellent for massing in mixed borders. These should be sown in specially prepared stations where they are intended to flower; they are invaluable for decorative purposes indoors. Clarkias are also useful for the mixed border and need much the same treatment as lavateras. Salvia Blue Beard is a most effective annual, which may be employed in various ways. It makes a pleasing combination with Hyacinthus candicans, which may be dotted over the bed. A mixed bed of salpiglossis always calls forth admiration. Nemesias cannot be excluded, as they are always admired either in beds by themselves or massed in their various colours in mixed borders. East Lothian stocks may be made use of for filling beds by themselves, and they must be sown early in the spring, pricking the young seedlings out singly into small 60-sized pots when large enough, and planting them out in April. They will commence flowering in July, and continue to bloom until the end of the season.

Dianthus Heddewigi is exceedingly valuable, and must also be sown early and treated liberally to obtain the best results. Gaillardias will respond to annual treatment if sown early enough, and treated liberally. These are invaluable for massing in clumps in the mixed border. Dimorphotheca aurantiaca deserves more extended cultivation, as it will bloom continuously during the greater part of the season if planted in a sunny situation.

Godetias deserve recognition in every garden, as they offer a wide range of most brilliant colouring. These may be grouped in separate colours in the mixed border or massed in several colours in beds or narrow boders. Lupins should be grown specially for the mixed border. Linum grandiflorum rubrum is always admired, and it is most effective when grown in large groups in the mixed border.

Eschscholtzias, of which there is now a charming variety, cannot be excluded. Cosmeas are very effective in the mixed border, but to obtain the best results they should be grown in pots until flowering commences.

Asters, coreopsis, Phlox Drummondi, Phacelia campanularia, petunias, nigellas, nasturtiums, nicotianas, centaureas, and annual chrysanthemums are all very useful annuals for summer bedding. It is a good plan to have a border of annuals of sufficient size to include many kinds and varieties, as, apart from those mentioned above, there are a host of others deserving of attention.

E. Harriss.

A BOLD ARRANGEMENT OF ANNUAL FLOWERS IN A SURREY GARDEN.

UNCOMMON VEGETABLES.

A marked feature in the development of our social life during the last twenty years, in its economic aspect, is the greater recognition of the dietetic value of fresh vegetables. This recognition is not, perhaps, as general as one might wish, nor has it yet reached its climax, but it is interesting to note that vegetables which were then considered as luxuries, and used only by a few, are to-day commodities deemed necessary by many. That this dietetic value of fresh vegetables is a real one is borne out by observation of children, in whose daily diet a regular supply of fresh vegetables forms an important part. If comparisons are made with other children fed largely on farinaceous foods, one cannot fail to notice the difference, and it is by no means difficult even in country villages, to determine the children belonging to a home which owns a well-cultivated vegetable garden.

The increased interest in vegetables and their cultivation has caused a much greater variety to be grown than formerly, though many kinds have not yet attained any great commercial value, yet much more, in the way of variety, is expected from the private gardener than was formerly the case.

Some of this interest may be due to the fact that people travel more, and acquire fresh tastes. Continental nations, as a rule, make greater use of vegetables as articles of food, and are generally credited with better methods of preparing them than the English.

Aubergines.

Among lesser-grown vegetables are the aubergines, or, as they are more generally known, "Egg Plants." The plant is an annual, and a near relative of the tomato; the fruits are used in similar ways. The taste to many is insipid, and has to be acquired, as with the tomato.

To obtain the best results the seeds should be sown, in light soil, early in the year—January or February—in a temperature of 60 to 65 degrees, and put when in the seed leaf into small 60's, or 72-sized pots. When established shift into 32's in rich compost, and pot firmly. At this stage a slightly lower temperature, with more air, is suitable. The plants "break" when about nine inches or one foot high, and may then be disbudded to two shoots, which may be allowed to carry two or three fruits each. These two shoots may be pinched and disbudded as the fruits form. From a March sowing plants may be set out on a spent hotbed in a pit or frame when large enough, planting about 15in. apart each way, but treating them otherwise in a similar manner to those in pots. Those in pots will need much feeding, or the fruits will fail to develop to any great size. Aubergines are particularly prone to attack by red spider, and the surroundings should be kept well damped, and the leaves well syringed on the under side. They are less trouble when planted out in frames, but in an unfavourable summer, such as that experienced last year, they are not as satisfactory as when grown in pots.

Good King Henry.

A native perennial plant used as a vegetable, and which I have only met with in East Yorkshire, but is, I believe, quite common in some parts of Lincolnshire, is one known as "Good King Henry." It is a species of chenopodium. The young shoots are much appreciated in spring in some districts.

The plant requires no particular attention, but if grown in rich soil the young growths are stronger, and therefore better than when the soil is poor. It is easily propagated from seeds or by division.

Maize.

We are, perhaps, indebted to our American visitors for the addition of maize, or Sweet Corn, to our list of vegetables. It was no doubt used long ago by Anglo-Indians, but Americans appear to have used it as a vegetable long before it was cultivated to any extent in England. Within recent years I have noticed fairly large plots planted with this crop in the market gardens in Middlesex, and there appears to be a fair demand for the green cobs in London hotels. The market gardeners dibble or sow the seeds thinly in frames or pits in April, over a gentle hotbed, and after hardening, lift, and transplant the seedlings in the latter part of May, about 18in. each way. The seeds may be sown singly in large 60's, where only a limited number of plants are wanted, but they must be planted out in good, rich soil before the pots are filled with roots, or growth will be checked.

New Zealand Spinach.

A useful vegetable, but not frequently seen in gardens is the New Zealand Spinach. Some years ago in the market gardens of Fulham, it was largely grown for picking during summer and early autumn, and the plants grew to a large size in the rich warm, sandy soil which had been well manured for generations. The practice there was to sow or plant between early crops of salads, at wide intervals, and intercrop again in the later ones while the plants were developing. The plants eventually had the plot to themselves, spaced at intervals of about 3ft. by 2ft.

In private gardens a few plants may be raised in pots in spring, placing a few seeds in a pot, and afterwards thinning to one, transferring them to the open ground in rich soil in May.

Celeriac.

This is another of the less common vegetables, which is now seen in some of the shop windows, although from experience there does not appear to be a great sale for it. The turnip-like roots are much appreciated by some people. The seeds are sown early in March, and the plants treated in the early stages in the same way as the celery used for salads. Like the celery it must be liberally supplied with moisture in all stages or the roots will be tough and stringy.

To obtain clean, well-shaped roots, free from coarse fibres, the soil must be rich, but free from raw manure. Contact with fresh or raw manures is apt to produce ill-formed roots, which, on cutting, are discoloured and rusted. Although shallow trenches facilitate watering in a dry period there need not be this labour spent on them, as in the case of celery, nor need the roots be planted deeply. When planting the distance apart may be 15in. each way or 1ft. by 18in. All lateral shoots should be pulled out. Abundance of water and liquid manure should be given in summer, and in August or early September the swollen roots should be earthed up, in order to blanch them.

The general practice is to lift the roots and store them in sand in October. The best-shaped roots are grown in a soil of a nature calculated to produce good carrots.

Cardoons.

The cardoon appears to be more appreciated on the Continent than in England. One serious objection to its cultivation in small gardens is the amount of room taken up by the plants. In habit of growth it resembles its relative, the Globe Artichoke, and, like it, is a perennial; usually it is raised from seeds each year. Seeds may be sown in April in a frame, over a spent hotbed, and the plants grown on and hardened ready for planting out in the latter half of May. It is unwise to allow plants to attain too large a size previous to planting out, or they may run to seed prematurely. The best method of planting is in trenches 4ft. apart, prepared as for celery, the plants being set out at 2ft. apart in the trench. Water freely in dry weather, and occasionally use liquid manure.

In September draw the leaves together, and bind them with bands of hay, the folds being placed closely together; afterwards earth up the crop with fine soil. If not used before frost sets in the cardoons must be protected, or lifted and stored.

F. Drew.

Reading University College Gardens.

NOVELTIES IN HARDY FLOWERS.

In this brief note it is proposed to touch lightly upon a number of hardy flowers that have gained some prominence during the last year, and so may be regarded as novelties. Sweet peas have been discussed already, and attention will be devoted to carnations and to dahlias in forthcoming issues; moreover, hardy trees and shrubs that are in any measure new were dealt with on a previous occasion. The scope of the present reference is, therefore, somewhat limited.

Antirrhinums are hardy plants, although they do not survive our damp winters in all gardens. These are unquestionably beautiful, and their popularity is already assured. All the leading seedsmen have excellent strains of tall, intermediate, and dwarf sections, and in many instances there are novelties in each section. The newer pink, rose, chamois, and vermilion shades are especially deserving of attention, but the older self colours must not be omitted. Rose Doré, listed in most catalogues, is a very meritorious variety. The varied colour forms of Dimmorphotheca aurantiaca owe a good deal of their popularity to Messrs. Barr and Sons, but on the rock garden or in a sunny season they will need no other aid than their own freedom and beauty to extend that popularity. The new Eschscholtzia Mikado (Gardiner) canaliculata with vivid orange, crinkled flowers, commends itself to lovers of brilliant annuals; and Lavatera Olbia (M. Prichard), lately brought into prominence, is sure to have admirers, as it reaches a height of from 3 to 6ft., and carries beautiful silvery or satin-rose flowers.

Astilbes have been greatly improved of late, and A. Rhemania (Profittlich), with pink plumes of violet-tipped flowers, is a striking novelty; while A. Avalanche (Waveren and Kruyff), of taller growth, has spikes of white flowers, and is especially fitted for the bog garden or moist border. Differing widely from these is A. simplicifolia, with white flowers, and a maximum height of six inches; it has been already grown in rock gardens where rare plants find a home. Patrinia palmata (Miss Willmott), with spreading heads of yellow flowers, is a dwarf summer-flowering plant, suitable for the rock garden, and Rodgersia tabuleris (A. Perry), with head of white, fragrant flowers, is a somewhat rare Chinese plant that produces large peltate leaves.

Lithospermum Froebelli (M. Prichard) has deep-blue flowers, and is a trailer. Also of trailing habit is Lysimachia Henryi (M. Prichard), a prostrate golden-flowered species. Two new wahlenbergias have made their debut; these are W. vincæflora (M. Prichard), rich blue; and W. gentianoides (Piper and Son), with drooping bright blue flowers. Each of these campanula-like flowers is a miniature plant adapted for the rock

Used in the Royal Gardens; throughout the grounds of the Royal International Horticultural Exhibition, 1912; by Local and Municipal Authorities, and by Horticulturists universally.

Sold Everywhere in Tins, 6d. and 1s.; and in Branded and Sealed Bags; 7 lbs., 2/6; 14 lbs., 4/6; 28 lbs., 7/6; 56 lbs., 12/6; 112 lbs., 20/-; or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order (except 6d. TINS).

YOUR GARDEN NEEDS

In the Spring the Gardener's fancy
Gladly turns to thoughts of CLAY'S.
Whose mysterious necromancy
Lessens care and toil repays.
Gardens burst in grateful smiling
When the FERTILIZER's near,
And, beneath its blest beguiling,
Leaf and Flower and Fruit appear.

WEBBS' NEW GUARDIAN.—Mr. Edwin Beckett, Aldenham Gardens, writes: "The heaviest cropper and best disease-resister we grow; unquestionably one of the very finest potatoes yet raised."

WEBBS' GOLDFINDER.—Awarded Honours at all leading Shows.

By Special Appointment

To H.M. The King.

WEBBS' POTATOES.

POPULAR AND PROFITABLE VARIETIES.

WEBBS' NEW "COLONIST" (First Early).—4s. per peck; 14s. per bushel. Kidney-shaped; heavy cropper, of very fine table quality. Mr. M. Bailey, Hindlip Park Gardens, writes: "Your potatoes—Colonist and Express—are marvellous croppers, of good size, and without disease."

WEBBS' NEW "FIRST CROP" (First Early).—4s. per peck; 14s. per bushel. Suitable for growing in frames. Pebble-shaped; white flesh; good cooker. Awarded the maximum number of 3 marks by the National Vegetable Society for its all-round merit."

WEBBS' NEW "GUARDIAN" (Second Early).—3s. 6d. per peck; 12s. per bushel. The best mid-season potato ever introduced. Wonderful cropper; good keeper, of first-class table quality; free from disease; and valuable for exhibition. Cannot be too highly recommended.

WEBBS' "WORDSLEY PRIDE" (Second Early) 3s. peck; 10s. 6d. bushel. An extraordinary cropper, producing an abundance of large handsome tubers; of great value for exhibition and equally suitable for table use.

WEBBS' "GOLDFINDER" (Main Crop).—3s. 6d. per peck; 12s. per bushel. A most handsome white-skinned variety; very productive. Tubers flattish-round, and unsurpassed for eating quality and exhibition. Winner of prizes throughout the Kingdom.

WEBBS' NEW "CHIEFTAIN" (Main Crop).—3s. 6d. peck; 12s. per bushel. A very fine white, oval-shaped variety; crops very heavily; keeps and cooks well. Splendid for exhibition.

For full particulars of WEBBS' POTATOES, see
WEBBS' SPRING CATALOGUE—POST FREE.

Rose Garden at Markyate Cell, designed and planted only last season. In August our client wrote "The Rose Garden is just a constant and unfailing pleasure. All has been done admirably."

GARDEN MAKING.

We have a special staff devoted exclusively to Landscape Gardening, and invite inquiry from all who contemplate making, or remodelling or extending their gardens. We prepare plans, designs, and estimates, in respect of any scheme suggested, so that at the outset our clients have a definite undertaking as to the nature of the work and its cost.

NO GARDEN TOO SMALL OR LARGE. Write for FREE BOOKLET on GARDEN DESIGN

R. WALLACE & Co., Colchester.

garden. Oxalis enneaphylla rosea (C. Elliott), from the Falkland Islands, is another rock garden plant of great beauty, its soft, rose-coloured flowers being freely produced in early summer. Silene Hookeri (T. S. Ware), a lovely rose-coloured Catchfly, flowers during June, and is a charming plant. Under the name of Phlox Arendsi (Arends) we have a quite new race of hardy flowers of varied colouring, derived, it is said, from P. canadensis and P. decussata; these were shown last July and attracted a great deal of attention. They should certainly be "made a note of." Lewisia Howelli (M. Prichard) is a rarity, its statice-like spikes of greenish-yellow flowers rising from a rosette of dwarf stout leaves; it will need careful handling. Celmesia spectabilis argentea (Bees, Lim.) is another plant needing special care, and in most parts of the country it will need the protection of a frame; its white flower-heads are three inches across.

is satin-white, with crimson centre. Pyrethrum Queen Mary (Miller), double, pink, has been shown so often that most people already know its worth.

The new lilies include a splendid addition in L. Warleyensis (Miss Willmott), a tall-growing kind, with numbers of orange, brown-spotted flowers on a fine spike. L. myriophyllum (R. Wallace and Co.), with its elegant leafage and large, white, yellow-throated flowers, was greatly admired at the International Horticultural Exhibition, and on the same occasion L. davuricum luteum (A. Perry), bright yellow, with brown spots, was very much in evidence. Kniphofia Unique (Wallace) and K. John Benary (J. Veitch and Sons) are two fine members of the Red Hot Poker family. The former is rich coral-red, but J. Benary is deep and brilliant red, and is one of the giants and a late-flowering member of the group. The new Montbretia Star of the East (Davison) is far and away the finest of its family, its

rosea superba (Whitelegg and Page), frequently shown in large masses early last year; its name suggests its colouring.

Turning to, and concluding with, the primula family, it is noticeable that Chinese species were fewer than usual; one, however, P. Knuthiana (J. Veitch and Sons) came from the Far East, and was collected by Mr. Purdom; it has rosy-lilac flowers, borne above neat rosettes of mealy leaves. P. Juliæ (W. Baker) hails from the Caucasus, and its purple-mauve flowers are very like those of the common primrose, except in colour. P. Warleyensis (Miss Willmott) is a tiny little plant, barely two inches high, but it bears purplish-lilac flowers quite freely; possibly it will have to be treated as an annual or biennial. P. Mrs. Douglas (J. Douglas) has handsome purple-blue flowers, and is of auricula-like habit, while Auricula Roxburgh (J. Douglas) is a delightful Alpine auricula, bearing fine trusses of purple-blue, white-centred blooms.

SAXIFRAGA ROSEA SUPERBA.

A remarkably effective variety with rich rose-red flowers, that has been well shown by Messrs. Whitelegg and Page, Chislehurst.

Delphiniums are strong favourites, and new varieties are always forthcoming; those calling for mention at present are Dusky Monarch (Kelway), dark purple, 8 to 10ft. high; Drake (Kelway), light blue, white centre; Tagalie (Kelway), semi-double, blue, white centre; Lovely (Kelway), deep blue and purple; Lavanda (Ferguson), large mauve flowers; and Harry Smeatham (Blackmore and Langdon), blue, with a purple line down each segment. Other good border plants of recent introduction are Aster Nancy Ballard (Ballard), a double Michaelmas daisy, with purplish-mauve flowers; Pentstemon Mrs. F. Fulford (Fulton), bearing rich red blooms; and Cheiranthus mutabilis, Keeley's var. (R. W. Rickards), a pretty wallflower with rose and purple flowers of distinct appearance. Two Oriental poppies, Edna Perry (A. Perry) and Perry's White (A. Perry), must be referred to. The former has salmon-pink, fringed flowers; and the latter yard-high spikes bearing yellow, orange suffused blooms, four inches across. Several new gladioli have appeared, but gladioli have to be very fine or distinct nowadays to secure awards. Crown Jewel (Kelway) is a lovely pink and yellow variety; Innocence (T. W. Le Page), pure white, belongs to the early or Colvillei set; Queen Mary (Barr and Sons), rich pink, white blotches, is also of this class, and so is Cardinal (E. H. Wheadon and Sons), a large salmon-red variety; Rosina (Blamfield) has soft pink flowers, and appeared in June last.

Yellow-flowered Eremuri increase, and two were added to them in 1912, i.e., E. Tubergeni (Wallace), a sulphur-yellow form of great beauty, rising about 4ft. high; and E. Golden Queen (J. Veitch and Sons), a charming lemon-yellow form obtained by crossing E. Warei with E. Bungei. One Nymphæa appeared last year, N. Attraction (L. de Rothschild). A good showy Saxifrage is S.

It may be added that all the foregoing novelties have gained an award at the R.H.S. or other prominent exhibitions.

Prunus triloba.—In the open ground the flowers of this showy member of the plum family sometimes suffer severely from late spring frosts, for which reason it is often trained to a wall. In this way the flowers develop unchecked, and when in good condition it must be regarded as one of the finest of wall shrubs, while it holds a similar position among those available for forcing, as under glass the slender shoots clothed with their charming semi-double pink blossoms, are very beautiful. Beside the numbers that are grown in this country great quantities are sent here from Holland and Belgium for flowering under glass. The allied Prunus or Cerasus sinensis or japonica, a smaller grower than the preceding, is also much valued for forcing.—W.

NOTES ON TUBEROUS BEGONIAS.

It is superfluous to say that tuberous begonias have been prominent in the van of floral progress, and certainly it would be difficult to mention any family of plants that can show such immense improvements and wonderful development during the past twenty-five years. This applies equally to habit, size, substance, and colours of the flowers and general excellence, and the exhibits that have been presented to public notice at large shows in recent years leads one to wonder whether any further advance is possible.

The combined efforts of several specialists, including Messrs. Cannell, Lemoine, Laing, Ware, Veitch, Blackmore and Langdon, etc., have brought about this wonderful change, and they have good reason to feel proud of the success which has attended their labours. If a gardener could have been found thirty years ago sufficiently bold and farseeing to predict that in the near future tuberous begonias would, to a considerable extent, supersede pelargoniums as bedding plants, he would have been regarded as talking nonsense.

For Garden Decoration.

We are obliged to admit that in very hot and dry seasons begonias are somewhat inferior to pelargoniums, while they are greatly superior to them in a normal, or dripping summer. The effect of heavy rains upon pelargoniums is to destroy their beauty for a week or two at least, and, on the other hand, these begonias appear the more resplendent after a short or prolonged rainfall. Nowhere have I seen such glorious displays as at Hampton Court gardens, where the value of massing on a large scale is amply demonstrated. These famous gardens are, from a gardening standpoint, in the country, and one cannot expect these pure-air plants to flourish in the same degree in the London parks.

An open position that is partially shaded during the middle of the day is found to be the most suitable when begonias are employed for garden decoration, and, perhaps, the best results are obtained when sandy loam enriched with old cow manure and flaky leaf-soil is provided. I cannot agree with some writers that the tubers should be started in heat early in February for bedding purposes, as, apart from the time and labour lost, the plants are not to be compared to those started later, and grown on under cool conditions. The middle of March is quite soon enough, and in order to economise space they may be arranged in shallow boxes filled with light rich soil, and be placed where they will have the assistance of a mild hotbed. Later, and when the growths are about two inches high, they should be transferred to large and fairly deep boxes, and be put six inches apart. If a little cocoanut fibre refuse is added to the compost they will lift with a large body of soil attached to the roots, and will receive no check whatever when placed in their permanent quarters. It is important they be kept, during the growing and hardening-off process, fairly close to the glass.

It is idle to expect success if the plants are allowed to suffer from drought after being planted out, and to reduce the labour of watering to a minimum I would advise that the beds be mulched with cow manure, preferably applied immediately after the ground has been loosened with a handfork. I have found nothing to equal the lawn sprinkler for watering purposes, and if it is allowed to remain half an hour at each station the ground is thoroughly moistened in every part. It may be added that in Western England the dry tubers are often planted out in April, but the practice is not to be recommended in less favourable parts. Appended is a list of double kinds that are specially suitable as bedders, and with regard to the single-flowered section there is no appreciable difference in their behaviour. The naming of these latter has, to a great extent, died out, but if procured from firms who have a reputation to maintain the highest form of excellence can be relied upon. I am reminded that the fringed and crested sections are possessed of much beauty and charm, and, to give credit where it is due, the perfecting of these types is the work of Messrs. Blackmore and Langdon, who also have produced some wonderful creations amonst the double varieties.

BEGONIA GLADYS VALENTINE.

An exquisitely beautiful variety, the flowers blush suffused with salmon. Raised by Messrs. T. S. Ware, Lim., Feltham.

For Beautifying the Conservatory.

Something must be said as to the management of begonias in pots, because in most gardens they figure largely in the decoration of the conservatory and greenhouse. It is usual to start batches of tubers at intervals from early in February to April, and in the same way as with bedders. The size of the pots from the outset will, of course, be regulated by the tubers and plants. It is important to give roomier quarters immediately the roots reach the sides of the pots, and to avoid overpotting. Further, it is a huge mistake to subject the plants to a high temperature, more especially in the early stages of their growth. Perhaps, from 60 to 65 degrees constitute ideal conditions.

It will occur to the cultivator to stage the plants fairly closely to the roof-glass whilst making their growth, also to supply atmospheric moisture by damping floor and staging, supplemented by overhead waterings daily until they are allowed to commence blooming. To maintain a buoyant atmosphere ventilate freely, and protect the plants from the direct rays of the sun during the hottest part of the day. From the time the plants are firmly established in the pots in which they are to bloom liquid manure may be applied once a week with advantage.

A few first-rate varieties for bedding purposes are Mrs. Langtry, white; Count Zeppelin, glowing scarlet; Gambetta, of similar colouring; Major Hope, a popular kind in light rose; Mrs. French, creamy-white; Hilda, deep salmon; Marquis of Stafford, crimson; Lafayette, crimson-scarlet; Rev. E. Lascelles, yellow; Hollyhock, pink; Argus, a pleasing shade of scarlet; Harry Laing, brick red; President Savage, lemon-yellow; R. B. Parsons, deep pink; Miss M. Griffith, blush; and Golden Crown, a fine sort.

For hanging baskets the following may be recommended: Lena, rosy-crimson; Starfish, of similar colour; Alice Manning, yellow; Fleur de Chrysanthéme, salmon-pink; Golden Shower, a great beauty; Carminia, carmine-red; Rose Cactus, rose-pink; Marie Bouchet, deep red, and extremely vigorous. Amongst a great galaxy of beauty I should select for pot culture, and especially for exhibition: Mary Pope, pure white; King Edward VII., crimson; Mrs. Augustus Philip Brandt, blush; Elaine, white; Miss Clara Sare, yellow, shaded gold; Kennerley Rumford, apricot; Lady Cromer, pearl-pink; Princess Victoria Louise, salmon-pink; Gladys Valentine, blush suffused with salmon; and Irene Tambling, fiery orange.

Walter H. Aggett.

PITS AND FRAMES.

During late years we have heard much about cloches, intensive cultivation, French gardening, and the like, but many who are strong advocates of this system fail to recognise the important part played in gardening by pits and frames, or ignore them altogether. Cloches may be very well, but I fail to see their very great merits. Certainly they are handy for protecting plants in the herbaceous borders against the inclement weather, or useful for putting over salads or herbs; but for bringing things forward I should much prefer a cold frame, as that does not entail half the labour.

I remember, when first starting gardening, more than half a century ago, that hand-lights were then much in vogue. A whole host of plants were protected by them, but, as glass became cheaper, these hand-lights gave place to frames. In some instances they were permanent structures made of bricks, while in others they were temporary ones made of rough boards. These latter answered the purpose very well. Stakes were driven into the ground wide enough apart to take the lights; to these rough boards were nailed, and by this means a frame was made as long as desired. A hotbed was made in a portion, if not the whole length, and over this a whole host of seeds were sown. In some instances the seeds were sown in boxes, in others they were sown in specially prepared soil. As the heat declined fresh beds were made, to which the more tender subjects were transferred, while those in which the heat was on the wane were used for pricking out cauliflowers, lettuces, celery, etc. These frames, with their glass lights, would hold far more than the same space covered with cloches, and could be readily covered at night with mats or other protecting material.

At that time I lived not far from the moors, where we could obtain plenty of ling, and this was made into mats by being woven into a frame made of wood, so as to form a kind of thatch. Mats of this description were warm, and would keep out much snow and rain, as well as the frost, and they were very portable, being readily handled by a man. In those days most of the early produce, such as potatoes, carrots, lettuce, celery, French beans, and the like were grown in these primitive structures. Some others were used for forcing asparagus, while bedding plants occupied not a few, the old hand-light, cloche, or other portable protector being discarded.

It would, however, appear that the cloche was a new invention, and so it may be in its present shape, but it has long since been put on one side by the more practical for something more useful and economical, such as pits, frames, and portable low houses, which are far less trouble, and give greater satisfaction. BED OF SEEDLING DOUBLE TUBEROUS BEGONIAS
In Messrs. Blackmore and Langdon's Nursery, Twerton Hill, Bath

Planting Vines.—Any preparations necessary should now be made for planting, but it is time enough for a couple of months yet to place the vines in the borders. Have in readiness a sufficient quantity of good loam, old mortar rubble, charred wood, and earth, bone-meal, and a little vine manure, if considered necessary, mixing all well together by turning several times. See that the drainage is perfectly clear before placing on the turf, grass side downwards, following afterwards with the compost, which can hardly be made too firm. Make the border about four feet wide. Those who intend planting one-year-old vines must disentangle the roots before planting, spreading them out carefully, and covering them with a nice sharp compost to the thickness of about three inches, giving a good watering afterwards with water at 75 degrees. I much prefer planting green vines in May or June, or even later, prepared from eyes.—F. Jordan, Warter Priory Gardens.

ROSE PLANTING IN SPRING.

Although it is undoubtedly best to plant roses in autumn, circumstances may prove too much for us, and then it behoves us to do the best we can in spring. In this connection February and March are the best months for transplanting roses grown in the open air, but April and the early part of May have been found most suitable for planting those from pots.

So much depends upon the preparation of soil that any labour in this direction is sure to be repaid. It is very essential to have the ground suitably moist, so that new roots can be formed quickly, and grow without check. A little extra attention is desirable in the matter of spreading the roots, and placing some soil among them; in fact, the whole operation of planting needs more care than would have sufficed under favourable conditions in autumn. I believe many failures in late spring planting are assisted (I will not say caused) by too loose planting. There is not the same amount of rain to press the soil that autumn-planted roses have received, and, although we do well by keeping the surface soil stirred, it appears to me to be best that where the roots are the ground should be firmer than is often the case for some time with spring-planted roses. If this is not so, why do so many of our old-established favourites thrive so well?

A mistake that I have only too frequently observed is that of leaving over-much growth upon the plants Doubtless, in most cases this is due to delay until what is considered a more seasonable date arrives. But it must be obvious that the quantity of shrivelled and distressed wood we so frequently meet with, more especially upon the stronger growers, is a great strain upon the roots that have not had time to feed the wood with more sap. In the ordinary course of autumn planting, we should cut away the top growth of most climbers, and I would do the same with most of our spring-planted roses at the time of, or very soon after, planting. There need be no fear of the same precocious growth among them as in established and early autumn-planted roses.

There is a method of spring planting that has proved very successful with us, and that is the use of small plants from pots. Oftentimes these can be procured at the same price as good ground plants; and, even if a little more expensive at first, we have a much better and more reliable display during the first season from planting them, and this is a great gain. If we do not secure much wood, it is always firm, and in the right place, instead of several feet away. The roots, too, are ready for immediate occupation of the fresh soil, and, having practically no check, soon make use of it. Another advantage lies in the almost certain absence of failures to grow, seeing the roots are already at home and established in the pot soil. Fortunately, all of our best and most reliable varieties from the tea-scented section and its hybrids can be readily purchased in this form, and, if planted well below the union of graft and stock, are quite equal to any budded plants from the open, seeing that nowadays the bud and graft are both worked lower than was the practice some years ago.

Even smaller plants than these can be obtained. I allude to the small, grafted plants that were propagated during the past winter, and it is astonishing what a display many of these will make during the summer. At all events, they will make really serviceable plants during the year, and will possess the great advantage of an abundance of fibrous roots.

The dwarf polyanthas, now so much used for bedding, will be a perfect picture during late summer and throughout the whole autumn if planted in this way. Bought in small pots, they are not expensive in the matter of carriage, while most of them may be carefully turned out of the pots, and thus less expense would be incurred. One point I must impress upon readers is, that, being in such tiny pots, the roses must be planted in soil that is quite moist. In our own case we always carefully water them before, or soon after, planting. The most suitable distances at which to plant depends so entirely upon the variety and its habit of growth, therefore I must leave that to the owner or planter, who should not neglect to become acquainted with the characteristics of the variety he is handling.

The filling-in of blanks, discovered at the time of pruning, may come under the heading of these notes, and I would merely reiterate the need for a little extra care, more especially as regards watering, for a short time, should the weather be dry, as the roses will have no far-reaching roots to keep them in such a case of necessity.

Rosarian.

ROSE LA TOSCA.

A beautiful hybrid tea with soft rose-pink flowers, of much value for bedding, having a good habit, and blooming freely and continuously.

ARRANGEMENT OF PLANTS FOR SUMMER DISPLAYS.

Well within the memory of most people great changes have taken place in the arrangement of plants for summer displays, and the different subjects that are employed for the purpose. To go back to the later 60's, nearly everyone seemed to be infatuated with the beauty of the ribbon border, that consisted of straight lines of brightly-coloured flowers, the longer the better. Whatever else might be planted, one was almost sure of finding scarlet pelargoniums, yellow calceolarias, blue lobelias, and Coleus Verschaffelti.

The advent of the bronze and tricolor-leaved pelargoniums, and the popularity they so quickly attained, led to great changes in the summer bedding, the displays being then less gorgeous than they formerly were.

The era of carpet bedding then followed, and to a certain extent continues to the present day, though it is decidedly less popular than it formerly was, the amount of time necessary to be spent over beds of this class being greatly against it. In positions, however, where the beds are looked down upon at close quarters, carpet bedding is still very effective.

A prominent feature of the present day is the extended use, for summer displays, of different hardy subjects, especially roses and the better-class of herbaceous plants. This, however, is not the only change that has taken place within the last few years, for, where tender plants are employed, the choice of subjects is not nearly so limited as it used to be, and in their arrangement a more informal and pleasing system of planting is generally followed. This allows for the employment of much larger plants than was at one time considered desirable, and now, especially in mixed beds which are so popular, plants up to six feet in height of such subjects as heliotropes, Streptosolen Jamesoni, Solanum jasminoides, Cassia corymbosa, Swainsonia galegifolia, Calceolaria Burbidgei, and others are often employed.

Fuchsias, which are now extensively used for summer displays, often as large specimens, do not, as a rule, associate with other subjects of equal stature, though violas as a groundwork for standard fuchsias of medium height, has a very pretty effect. For very large fuchsias an undergrowth and edging of some of the smaller kinds, such as Alice Hoffmann and Ida Noack, with the variegated-leaved form of Fuchsia gracilis, and the coloured kinds, such as Cloth of Gold and Meteor, may be used with advantage.

An item of considerable interest when the question of summer bedding is under consideration is at what part of the season the display is required to be at its best. Thus some annuals make, for a time, a goodly show, but they are in many cases over so soon that it is necessary to replace them before the season ends. Fuchsias, on the other hand, and in fact many things, retain their beauty till the nights grow very cold.

Calceolarias, especially the larger growers, still hold their own as desirable subjects for summer bedding, while pelargoniums are not yet out of the running. The advent of Paul Crampel and the improvement in the ivy-leaved section has kept pelargoniums well to the front. For a mass of brilliant colouring the variety of Salvia splendens known as Pride of Zurich, still holds its own with the brightest of the zonal pelargoniums, while marguerites, especially since the double-flowered Mrs. Sander has become so widely distributed, are now extensively grown.

As a foil to flowers of vivid tints, many foliage plants are very popular. The silvery-white Leucophyta or Calocephalus Browni may be pegged down as an edging, or, if grown as an upright specimen from 18in. to 3ft. in height, it is extremely useful as a dot plant. Others of that hoary tint are Artemisia arborea, Gnaphalium microphyllum, Cineraria maritima, Centaureas, with Antennaria tomentosa and Cerastium tomentosum, these last two being of very lowly stature, and therefore suitable only for edging or carpeting purposes. With the various subjects above alluded to, and others innumerable, it is evident that combinations without number can be made. The system followed in the case of these arrangements will, of course, depend upon many circumstances, such as the surroundings of the beds, the position from which they are chiefly viewed, and, above all, the fancy of the individual by whom they are planned, or more often of those to whom he is responsible. The stock that is available of any particular subject also plays an important part in the matter, so that suggestions cannot always be carried out in their entirety.

Still, the following arrangements which have been made within the last two or three years gave universal satisfaction: A groundwork of Koniga maritima, dotted over with double pink Begonia Major Hope, and, above these, a few 2ft. plants of Leucophyta Browni, edged with Echeveria secunda glauca. Salvia Pride of Zurich, dotted over with tall plants of Leucophyta Browni. Begonia Triomphe de Lorraine, one of the semperflorens section, with double crimson flower and leaf of much the same tint, interspersed with Fuchsia gracilis variegata and Centaurea candidissima,

MARGUERITE MRS. F. SANDER.

A bold arrangement of this free-flowering pure white double marguerite, which has proved of much value as a summer bedder.

edged with Koniga maritima. A carpet of blue viola, with Canna Paul Bert (amber) scattered over the whole, overtopped with plumes of Humea elegans. Dwarf crimson Begonia Washington and Koniga maritima, interspersed, and dotted over with Leucophyta Browni.

As a concluding note mention must be made of that comparatively new annual, Kochia tricophylla, the various uses to which it may be put, and the fact that it rapidly bounded into popularity, its quick growth, delightful leafage, and the change in colour that takes place in the autumn, are all features of interest. W. T.

PLANTING SWEET PEAS.

The unusually mild weather of January and February seems to have given us false ideas of how far the season has advanced, but each week brings us so much nearer to that period of activity and hopefulness—the planting season.

Many of us have very divided interests, and, should the coming season not be quite favourable for one thing, it will surely be of such a character that it will prove happy for at least one or two of the subjects that we cultivate. Disappointments may be ahead of us, but we hope they will be balanced by a fair amount of success.

Naturally, the lover of sweet peas is hoping that the weather will favour his own particular fancy, and after two such seasons as those of 1911 and 1912, the one so very hot and the other (after May) so very cold and wet, he may be excused if he is optimistic enough to think that he is in for a really good sweet pea season in 1913.

Up to the time of writing the weather has not been all that one would desire to bring the soil into that state of mellowness which is so necessary for planting; on the other hand, heavy soil generally is in a very wet or waterlogged condition, and some time must elapse before anything can be done to bring it into a nice workable condition. Fortunately there is still time for the ground to dry well before planting, for even in very favoured localities, and on light soil, it is not safe to plant out sweet peas before the second week in March. This is the earliest date that I have planted—and, I might add, with excellent results—but owing to adverse weather conditions I have had to leave planting as late as April 23, and even at this late date the plants had a good covering of snow, and twelve degrees of frost, before they had been in the ground two days, and yet no harm came.

The necessity for thoroughly hardening the plants cannot be too fully emphasised, as half the failures that one hears of after planting can be traced to coddling in the frame previous to planting, or to thick sowing in pots or boxes, which amounts to the same thing. When the plants are too close together, or growing too thickly, air cannot get among them, and the foliage and stems are badly nourished and thin, so, instead of growing away freely and becoming a good colour when planted out, they turn yellow, and if they do not actually die they are weeks before they get over the check, and the flowers are thin, which spells failure at an exhibition.

After the end of February we do not expect very severe frosts, and, if the lights are left off in anticipation of a fairly mild night, the degree or two of frost we sometimes get in the morning will not harm sweet peas; but, of course, there is a difference between a prolonged frost of seven or eight degrees and an occasional light one. The severe frost would probably freeze the pots right through, and might kill a great many of the young roots; so be cautious, remembering that sweet peas withstand twice this amount of frost after they are planted in the ground, where the roots are thoroughly protected by the soil.

This hardening process and the actual preparation of the soil are the two chief points to be considered, presuming, of course, that the ground has already been trenched and left rough. It is now considered advisable to give the ground a slight dressing of sulphate of potash some little time before planting, and if this is given at once, with an equal proportion of superphosphate, there should be sufficient manure in the soil to last the plants a considerable time, certainly until they are well advanced in growth.

Light, porous soil will only need lightly forking over just previous to planting, and, as already intimated, any time after the second week in March the plants should be as safe in the ground as in the frames. Heavier soils will probably need much more care, taking advantage of a good dry spell to get the whole surface of the soil thoroughly broken up either with the fork or harrow. This may need to be done two or three times before planting. The addition of old potting soil, leaf-mould, old hotbed manure, wood ashes, or mortar rubble will all help to make heavy soil more friable, and if this cannot be obtained in sufficient quantities to spread over the whole patch, a little might be worked in when the rows or clumps are to be planted.

I have many times advocated shaking out the roots well before planting, and, after further experience, I feel even more sure of its benefits. Even when the plants are raised singly in pots a certain amount of the roots should be shaken free of the ball of soil. The advantage of this is not so apparent immediately after planting, but in a fortnight plants so treated invariably look better, and commence growing away more freely than when the ball of soil is left intact, and, even where the plants are raised in the T.P. seed raisers (which, by the way, are splendid contrivances in which to raise a large number of plants in a small space), they should be given the same treatment, and not planted with the stiff paper raisers still around them. A good hole and firm planting are also essential, and without thorough tilling of the soil this cannot be nicely accomplished.

The number of plants and amount of space available will naturally control the amount of room each plant is to occupy, but double rows, five feet apart, is about the minimum that can be allowed if convenience in staking, watering, cutting, etc., is to be considered, and an extra foot or two of space between the rows will tend to sturdier growth and greater convenience in working. It matters very little which way the rows run, providing they have plenty of room, but those varieties that require shading may advantageously be planted all together in a row running east and west, as the shading will then be much more easily fixed, and need only be put up on one side of the row.

Staking and sooting, after planting, must be properly attended to, or slugs may do a lot of harm, and birds, too, must be guarded against. This may all seem a lot of bother, but it is the proper attention to details, especially at the outset, that is the keynote of success, and without it no one can hope to excel in the cultivation of any particular plant or flower.

Thomas Stevenson.

Woburn Place Gardens.

THE ROCK GARDEN IN MARCH.

"The sap will surely quicken soon or late,
The tardiest bird will twitter to a mate;
The spring must dawn again with warmth and bloom."

Christina C. Rossetti.

With March, we who are lovers of the alpine flowers feel that we are entering into our truest pleasures, and that spring has really come. Even now we are having a foretaste of the many treasures which the milder days will bring. On slope and in crevice of the rock garden there are already many beautiful flowers which have called for our glad welcome.

Many days, it is true, may pass over us before we can say that wintry weather has really passed away, and that the blossoming days have come with their full benison. Snell winds will blow and shrivel up some tender blooms, or wither up our hopes of the morrow during the dark hours of the night. Snow, and sleet, and bitter rains may yet drench our alpine flowers, and cause us to lament for their distressful plight. Yet it is of no use to despair; the story of the past will be repeated, and we shall surely again enter into our full joys. These are, to a large extent, the pleasures of anticipation, but it is our duty now to ensure for our favourites all the attention they desire at this season. The work of the time will bring the reward of the morrow, and we may well take count of what our plants call for as March begins to run its course.

Planting.

Now, and later, there is much planting to be performed. There are blanks, the result of the winter's assaults, to fill. Bare spots have to be clad, and with the earlier alpines this planting must be taken in hand at once. It is work which should be carefully performed, and not gone about in a haphazard fashion.

We should have some proper soil prepared for the pockets or crevices into which the plants are to go. Loam, leaf-soil, and sand, in about equal proportions, with the addition of some grit, will be a suitable compost for the greater number of our alpines. Some chips of stone among this will be useful; and for the few plants which really need lime or are benefited by it, limestone, in the form of chips or old broken mortar, may enter into the compost. If the plants are turned out of pots the outside of the ball should be slightly loosened; if full of roots some of these ought to be disentangled, and the whole planted with as little further disturbance as possible. If the plants are not in pots they require more care. Should the weather be dry the alpines should have their roots spread out as well as the space will permit, except in the case of deep-rooted subjects, a little soil put over the roots, and the hole filled up with water, adding more earth, and watering again when the former supply has drained away. The hole may then be filled up completely, and a few pieces of stone, or some grit and chips, placed about the plant to prevent evaporation, unless in a crevice of the rocks, where this can hardly be done. Firm planting is most essential, and many alpines are annually lost from the temerity of the grower, who is afraid to press the soil about the plants.

Top-dressing.

"Top-dress! Top-dress!" should be one of the maxims of the cultivator of rock plants, and more alpines are lost from neglect of this than from almost any other cause. All the plants should be gone carefully over at this season, loose leaves which have blown among them removed, and

decayed material taken from about them. Then some fine compost of the character just mentioned ought to be well tucked in about the plants, and worked into the tufts of the low-growing mat-like subjects, as well as some of the others. Many alpines have a tendency to grow out of the soil, and these are generally greatly assisted by some top-dressing. It hardly ever comes amiss, and that worked among the foliage may be watered in if the weather be dry.

Tidying Up.

This is an excellent time for a general "titivating" of the rock garden. Any unsightly plants should be removed, and everything made as neat as is compatible with the genius of the garden. Nowhere is a little work of this kind more noticeable than in the rock garden. Among other items which should be attended to is that of forking up the soil about the plants. This is not inconsistent with firm planting, and the loosening of the surface which is uncovered by stones prevents the hasty evaporation of the moisture underneath, and adds greatly to the well-kept appearance of the rockery and the plants upon it.

Watering.

The question of watering must always be approached with caution, especially at this season. Artificial watering is not to be commended, save under certain conditions. These conditions sometimes arise in March, when a parching wind licks up all the moisture, and is most injurious to our flowers. It is thus necessary at times to give a supply of water. Should this be so it ought to be given with a generous hand, not a miserly one, as a mere sprinkling does harm instead of good. If at all possible the water should be poured beside, and not on the plant. It is hardly possible to give too much water if the rock garden is as well-drained as it should be. Should the evenings be mild, which is not too often the case, a gentle dewing with water is often helpful, but it should never be applied unless the plants are moist at the roots.

Seed Sowing.

More and more are we realising the advantages of raising alpine flowers from seeds, and from now until May will be found as good a time as any for raising rock plants in this way for next year's bloom. It is needless to detail the methods to be followed, but it may be said that, as a rule, the seeds should be sown very thinly in pots, and not in the open ground.

Briefly stated, the arguments for raising more vigorous plants, having the plants at hand ready to put out at the more "convenient season," and the chance of securing improved varieties. Against these are to be set the additional labour and space required. It is for the reader to choose between the two courses. In any case he will find that March among the alpines is not only a time of enjoyment of the flowers, but is also one when there is much work to perform. S. Arnott.

Lachenalias.—The Cape Primroses, as these are sometimes termed, form a very pleasing feature in the greenhouse early in spring. Whether grown in pots or suspended baskets, they are very pretty. Good distinct kinds are L. Nelsoni, L. pendula, and L. tricolor. The failures that one sometimes hears of are due to their being potted too late in the season, as they should be in their flowering pots by August.—K.

ARAUCARIA EXCELSA.

The Norfolk Island pine has long been looked upon as most desirable for the decoration of the greenhouse or conservatory, while it also figures as one of the most popular subjects for the dwelling-house. From some points of view the extreme regularity of its growth is looked upon as too formal, while by others it is admired. Plants from a foot to eighteen inches in height are disposed of in considerable numbers by some nurserymen. They are obtained in two ways, the first by seeds and the second by means of cuttings.

In the case of cuttings, though the side branches may be rooted, they will not form effective plants, therefore, in order to obtain cuttings, plants that have become bare at the base or in other ways shabby may have the top or leader cut off. This will lead to one, two, or more side shoots being pushed up in order to replace the leader, and these shoots, being taken off and inserted into small pots of sandy soil, will soon root in a close propagating case, where there is a gentle bottom heat. Plants so obtained realise a higher price than seedlings, as they are well furnished at the base, whereas seedlings have only small branches at the bottom, and therefore present a much less pleasing appearance.

Of late we have had two distinct varieties of this araucaria brought prominently forward, one, elegantissima aurea, having all the young shoots tinged with yellow; and the other, Silver Star, every shoot of which is tipped with white. An older form, glauca, of more sturdy habit than the type, with beautiful glaucous foliage, is also very handsome, and should be grown wherever the forms of the Norfolk Island pine are appreciated. W. T.

PHLOX AMŒNA.

An effective specimen of this beautiful species which has rose-pink flowers.

NEW PLANTS AND FLOWERS.

BRASSO-CATTLEYA MENDA.

A very beautiful orchid and a secondary cross, obtained by using B.-c. Digbyano-Mossiæ var. Queen Alexandra and Cattleya labiata Virginia as parents. The flowers are about one-third larger than illustrated, with broad white petals and tinted white sepals. The large fringed lip is white, with a lemon-yellow throat and a bright purple mark on the front. F.C.C., R.H.S., February 18. Pantia Ralli, Esq. (gardener, Mr. Hunt), Ashtead Park, near Leatherhead.

BRASSO-CATTLEYA MENDA.
Flowers white, with a white and yello w, purple-marked lip. F.C.C., R.H.S., February 18. Pantia Ralli, Esq., Ashtead P ark, near Leatherhead.

BRASSO-CATTLEYA AMABILIS GOODSON'S VAR.

A very handsome form, of fine size and colour. The rosy-purple sepals and petals display the broad, purple, fringed, and yellow-throated lip to perfection. F.C.C., R.H.S., February 18. H. S. Goodson, Esq. (gardener, Mr. G. Day), Fairlawn, Putney.

CATTLEYA LEDA.

A fine hybrid between C. Percivaliana and C. Dowiana aurea. The colouring is deep rose, the lip being beautifully veined and shaded with deep gold. A.M., R.H.S., February 18. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester.

CATTLEYA TRIANÆ THE BARON.

A white variety of wonderful size and substance, the only colouring being the rose-pink shading and the yellow throat of the lip. F.C.C., R.H.S., February 18. Baron Bruno Schroder (gardener, Mr. J. Shill), The Dell, Egham.

CYMBIDIUM ALEXANDERI FOWLER'S VAR.

This is dwarfer than most of the hybrids from C. insigne, and this is due to the use of C. eburneo-Lowianum as the second parent. The flowers are of good size, deep pink, with rosy lines. Lip creamy-white, with deep rose-red markings. F.C.C., R.H.S., February 18. J. Gurney Fowler, Esq., Glebelands, South Woodford.

ODONTOGLOSSUM AMETHYST GLEBELAND'S VAR.

A splendid odontoglossum derived from O. Lambeauianum and O. eximium. It bore a grand spike of showy flowers; white ground flushed with pink, but very largely covered with bright red-brown blotches, except on the front of the lip, which is quite white. F.C.C., R.H.S., February 18. J. Gurney Fowler, Esq. (gardener, Mr. J. Davis), Glebelands, South Woodford.

CROCUS KATHLEEN PARLOW.

The finest and largest of all white crocuses. It is of Dutch origin, and belongs to the bedding section. It is a strong grower, and the large flowers are of fine substance; the three inner segments having a faint rose-purple line down the centre of the inner surface. A.M., R.H.S., February 18. Messrs. Cartwright and Goodwin, Kidderminster.

SUPPLIES OF GREEN VEGETABLES.—I.

There are seasons of the year when green vegetables are indispensable, while at others they are not of so much importance, or in such great demand; this being so, the aim of all gardeners should be to have a good supply at those particular seasons when most needed, and arrange the cropping of the ground so as not to have either a glut or a dearth at any time of the year. A good kitchen gardener, by his superior judgment and forethought, will be able to adjust the crops so as to economise the space at his disposal, but this needs close observation if there is to be no waste of any kind, especially in large establishments where the demand fluctuates considerably, for, however one may strive to keep within the mark, there are occasions when sudden and unlooked-for demands arise. It is in this department that most young gardeners who have not hitherto had much experience in kitchen gardening sometimes find themselves in difficulties, especially in places where the area allotted to the growth of vegetables is limited.

Broccoli.

This is one of the most important of winter and spring green crops, being in use from November until May. By sowing seeds of each section into which they are divided, a successive supply may be obtained through those months. Seed of the autumn kinds, such as Michaelmas White and Autumn Protecting, should be sown either in boxes, which should afterwards be placed in a cold frame, or on a shelf in a cool house, until germination takes place, or, in more favourable districts, sown on a warm border in February. The plants should be induced to grow as sturdily as possible from the first, and be put in their permanent quarters before they become drawn. The second section, which includes Winter Mammoth, Snow's White, Penzance, and the sprouting kinds, should be sown on a warm border early in March. For mid-season use Leamington, Main Crop, Safeguard, and the like, may be grown. The seeds of these ought to be sown the first week in April, while the sowing of such late kinds as Standwell, Universal, Latest of All, and Late Queen should take place from the middle of April to the first week in May, according to the district in which they are grown.

Broccolis are most in request during the dull winter months, therefore the aim should be to have a good supply at that season, and this cannot be secured unless due attention be paid to sowing the seeds at the proper time, and growing the plants as sturdy as possible through the summer. It is a mistake to plant broccolis between other crops, as they become drawn up, and, on that account, will not withstand the frost. A portion of this section should be

CANARY GUANO

The Best Fertilizer for

GARDEN AND GREENHOUSE

Canary Guano is not a stimulant, but a food for all plant life. It is manufactured by The Chemical Union, Ltd, in connection with their associated firm, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, and the largest manufacturers of Special Fertilizers for individual crops.

Sold by Seedsmen, etc., in Tins, 6d., 1/-, & 2/6 each. Bags: 14lb., 3/6; 28lb., 6/-; 56lb., 11/-; & 1 cwt., 20/- each.

For producing prize-winning Flowers, Fruit, and Vegetables; for renovating Lawns, Cricket Pitches, and Golf Greens; for invigorating Palms, Aspidistras, and all Foliage Plants; and for promoting blooms in window Gardening, there is no Fertilizer that gives such excellent results at such a moderate cost as Canary Guano.

ONCE TRIED ALWAYS USED.

Full particulars sent post free on receipt of enquiry by the Manufacturers:—

NO SPIRIT REQUIRED. NO LIQUID POISON.

Efficiency and strength guaranteed by the oldest established Manufacturers of Horticultural Specialities.

SOLD BY NURSERYMEN, SEEDSMEN & FLORISTS THROUGHOUT THE WORLD.

lifted in November, and planted in pits, where they can be protected from frost. The others should be planted on a warm border, with their heads facing north, where, in severe weather, mats or other material can be thrown over them. The mistake often made in growing broccoli is keeping the plants too long in the seed beds; plants that become drawn seldom give satisfaction. As soon as they are large enough to handle they should be pricked out at least six inches apart, to induce them to grow strong from the commencement. A mistake often made is sowing the seeds too early, and leaving the plants to become overgrown before they are put into their winter quarters. There is more art in growing first-class broccoli than would appear if close heads of fine white texture are to be had, therefore particular attention should be paid to sowing the seeds at the right time, and getting the plants into their summer quarters as early as possible.

Brussels Sprouts.

For autumn and winter use these occupy a prominent place, and as they require a long season of growth, it is necessary to sow the seeds fairly early, but there is no advantage in sowing too soon, and afterwards allowing the plants to stand in the seed beds until they become leggy. The middle of March will be found soon enough in most districts. If the ground is too cold for the seeds in the open, then sow in a box or cold frame, but we have always had the best results from seeds sown thinly on a warm border. The soil should be made as fine as possible, and, if heavy, given a sprinkling of wood ashes or newly-slaked lime. It is preferable to sow the seeds in shallow drills, and prick out the plants when they have made three or four rough leaves.

Where the situation is exposed, it is better to plant in shallow drills, and when the plants are about a foot high level the soil round the stems; this will help them to resist the force of the wind, and maintain themselves in a perpendicular position. Often when planted on the surface they are carried over by the wind, in which case the sprouts produced are not so fine. The distance the plants should be set apart greatly depends on the quality of the soil. In some gardens, where this is a deep, well-cultivated medium, a distance of three feet each way will be found none too much, while, in others, too feet six inches will be ample. Brussels sprouts are most appreciated from November until February or March, after which they are but little in request.

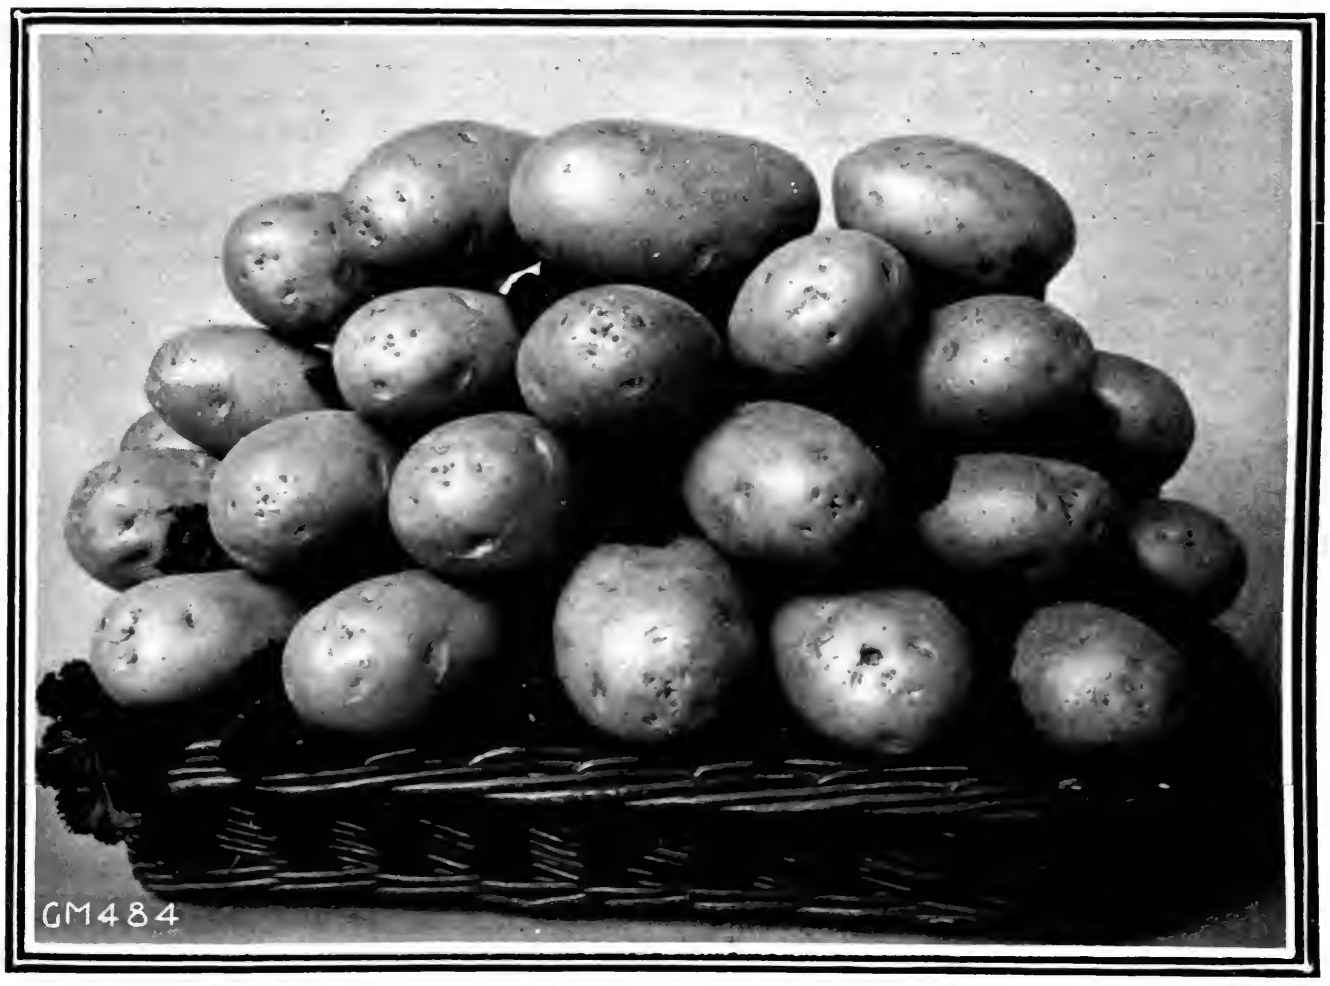
Borecoles.

The young, tender sprouts of these vegetables are much appreciated in early spring, especially those of the Asparagus Kale type, such as Sutton's Favourite, the old Asparagus Kale, Scotch Green Curled, and others of that class. The variegated kinds find but little favour with first-class cooks, as they do not boil a good colour. Seeds should be sown at the end of March, or early in April, and the plants set out in their permanent quarters as soon as large enough to handle. The distance between the plants must be regulated by the quality of the soil and the variety cultivated. There is nothing gained by planting closely. Some have an idea that if the hearts are taken out of the plants in early spring this will induce them to throw out more sprouts, but this is a mistake, as the wet often runs down the centre of the stalk, and causes rot, besides, as the plants grow, more sprouts are produced from the base of the leaf stalks.

H. C. Prinsep.

FIRST AND SECOND EARLY POTATOES.

The time of year is fast approaching when special thoughts must be given to this important crop, particularly the first earlies. To secure early potatoes one cannot urge too strongly the necessity of having the "sets" in proper condition when planting time arrives. The first consideration is to stand the tubers in boxes, "eyes" upwards, in a cool, light place, free from frosts or cold cutting winds, where they must be encouraged to form two or three firm, strong growths, all others being rubbed off as they appear. An occasional spray from the syringe may be required if the early varieties are backward, or brought in later. The later varieties will not require this latter attention as they should be quite early enough by planting time, providing they are all given the same box treatment at once. The boxing of potatoes may appear trivial, but it is a method which results in even foliage and a full supply of good-sized tubers, because a quick growth is being maintained, and no useless energy is spent on blanched and drawn growth previous to planting.



POTATO MIDLOTHIAN EARLY.

A fine basket of this excellent second-early potato, shown at the National Vegetable Society's exhibition by Messrs. Dobbie and Co., by whom it was introduced.

Early Varieties.

The time to plant the early potatoes will depend largely upon the position of the garden, and the part of the country. In most cases the first week in March will be soon enough. Here we plant a few rows on an early border the second week in February, between lines of peas, placing the latter so that there are three lines of potatoes between two rows of peas. The pea stakes protect the potatoes; if late spring frosts are feared a mat is thrown over the rows at night. In this way we usually are able to dig potatoes the last week in May.

Another plan is to plant at the foot of a south fence or wall, placing just one row of potatoes a foot from the wall, and parallel with it; the crop can be easily protected with boughs or canvas when necessary.

There may be many good and reliable varieties suitable for early crops, but it is not advisable to grow many sorts. A good selection of Midlothian Early is very hard to beat, whether for an amateur or otherwise, especially where the yellow varieties are sought after; this variety has a hardy and sturdy constitution, with very dwarf foliage. It is a very heavy cropper, and of splendid cooking quality. It does well both on light and heavy land, and a good breadth should be planted also for the second crop, as the variety remains fit for use over a long period. May Queen is another very necessary potato, being a heavy cropper, splendid grower, and remarkably good cooker, even when lifted quite small. Ringleader, a very early variety, that does well here, is not such a heavy cropper as the two others, but perhaps the best early flavoured potato we possess. Webb's Express, an excellent variety, heavy cropper, with shapely, medium-sized tubers, deserves to be grown more largely.

Providing the ground for early potatoes was manured and dug early, it should be in a good friable condition at planting time. Previous to planting, fork over the surface, and bring it to a good tilth. Take out trenches four in ches deep, place the "sets" therein, and cover them over with soil from hotbeds, etc., which should contain some burnt garden refuse. Keep the trenches two feet apart, and place the "sets" a foot apart.

The Second Earlies.

This batch, of course, will be larger than the earliest, and be planted on an open site. The first week in April is quite soon enough to plant, although a week earlier will be an advantage if the ground is in good condition. Superlative is a very reliable variety to grow, being of excellent flavour when lifted early, besides being an excellent cropper. Royal Kidney is another highly-flavoured variety, especially on heavy land. Carter's Flourball, a round potato, is a very heavy cropper, and quite "floury" when cooked. Windsor Castle, one of the finest-flavoured potatoes we have, is so liable to disease here that we have discarded it, but where it can be grown its flavour should give it a place. All this set should be planted in lines two feet six inches apart, and fifteen or sixteen inches apart in the rows.

G. Ellwood.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

ANGRÆCUMS.—The dwarf angræcums will now be showing signs of activity, by producing their flower scapes or growths; these should now have every assistance, and should any plants require new compost, excepting those that are likely to flower within a short period, repotting may now be done. The drainage used should be clean and ample, and as most of the dwarf-growing kinds lend themselves to basket or shallow-pan culture, every care must be taken to see that no great bulk of compost is used, and that the material is of a porous nature. In fact, the atmospheric conditions provided will determine failure or success. Sphagnum moss, chopped moderately fine and intermixed with silver sand or finely-broken crocks, will provide all that is necessary as a rooting medium, and if peat or osmunda fibre is used all the fine particles must be first abstracted; the fibre should be chopped finely and mixed in about equal proportions with the sphagnum moss. Hot, humid conditions are essential throughout the year. The larger growing kinds, A. eburneum and A. sesquipedale will also be now producing their flower scapes, and should have every encouragement. The first-named species does not usually require annual repotting, so that where the compost has decayed on the surface, it should now be removed, and fresh material be given. The spring-flowering type of A. sesquipedale may be repotted as soon as it passes out of flower.

RENANTHERA IMSCHOOTIANA.—The introduction of this species in larger quantities and its more general cultivation are a sufficient proof of its utility. The lasting qualities of the flowers, combined with grace of spike and brilliancy of colouring, render this orchid one of the most serviceable for house and table decoration through the late spring and summer months, and there is nothing more attractive for exhibition. The plants are in a more or less active state of growth during the greater part of the winter months, and during this period a warm, moist atmosphere, such as that found suitable for phalænopsis, is required, and this must be maintained, with rather more light, until the plants come into flower. During the summer and autumn, after flowering, a cool, intermediate temperature, with less root moisture, will be found suitable. Like most of this class of plant potting should not be done more frequently than is absolutely necessary. Remove as much of the old potting compost as may be thought desirable, and replace with new material, rather than disturb the roots. Here again, the condition of the atmosphere will determine the measure of success, and the question of compost is only of a secondary importance. When repotting use plenty of clean drainage and a free, open compost of finely chopped polypodium or osmunda fibre, mixed with sphagnum moss and sand, crocks, or charcoal.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

STREPTOCARPUSES. — Young plants raised from seeds sown in January should now be ready for pricking off. A compost similar to that recommended for gloxinias is suitable. The seedlings, which require careful handling, may be pricked out into pans about three inches apart. The stove shelf is a suitable place for them, and careful watering and shading from bright sunshine is necessary. Older plants which have been kept in cooler quarters may be turned out of their pots, the roots carefully reduced, and then repotted, using larger pots. A warm pit with a genial atmosphere will suit them nicely. When well rooted an occasional application of liquid manure, and also of soot water, will assist in the production of an abundance of flowers through the early summer months. An occasional fumigation may be necessary to keep down aphides.

GESNERAS FOR WINTER FLOWERING.—As the flowering season passes these may have all flower spikes removed, and for a few weeks they should occupy an open position in a warm house, in order to fully develop their corms before ripening them. To this end an occasional feeding will materially assist them. Water may then be gradually withheld, and when thoroughly ripened they may be stored under the staging until required for starting at the end of June. G. exoniensis and G. refulgens are suitable varieties for this purpose.

MARANTAS.—These beautiful stove foliage plants may be successfully grown if a strong, moist heat can be afforded. The present is a suitable time for repotting, and the soil they delight in consists of good fibrous peat, a little rich loam, and sand. Pots must be clean and well drained, for, although they enjoy liberal waterings when growing, moisture must not become stagnant in the soil. They may be increased by root division.

IXORAS.—Plants intended for late summer flowering should at once be started. When growth commences they may be repotted, using peat and loam in fibrous condition, to which a proportion of about one-seventh of sand is added. While making their growth they require shade, a moist atmosphere, and a good supply of water. As the growth is completed less shade will be necessary, and they may be kept a little drier until the flowers are formed. Like many other stove plants they are very liable to attacks of thrip, red spider, scale, and mealy bug, and great care must be taken to keep them clean. Fumigation must not be practised after the flowers have formed, for this causes them to fall.

PROPAGATION should be continued. Cuttings of Centropogon Lucyanus, Strobilanthus, Goodyeras, Plumbago rosea, and Coleus thyrsoideus are among those which may be inserted when obtainable.

SHADING.—As the sun becomes more powerful it will be necessary to attend to shading, and blinds should be fixed without delay.—H. Prime, Hatfield House Gardens.

FRUITS UNDER GLASS.

POT VINES, started in November, will now require plenty of weak liquid manure and other stimulants, especially during the second swelling, but feeding should be discontinued when the grapes begin to colour. Do not pinch the laterals more than can be helped; rather encourage leaf development, as this will improve the size and colour of the fruit. If red spider makes its appearance, sponge the leaves, as the slightest injury to the foliage at this early season will check the proper swelling of the grapes.

LATE HOUSES.—In order to give the late vines time to finish their fruit and mature their wood by the end of September, all the late houses should be closed now. Syringe the vines as previously recommended, and merely give as much fire-heat as will prevent any stagnation of the atmosphere.

PLUMS AND CHERRIES.—Where the fruits have set, either on pot or permanent trees, an advance of 5 degrees may be given in the temperature, with free use of the syringe. Later trees in flower must be kept steady with a night temperature of 45 to 50 degrees; it is fatal to over-excite them until they have set their fruits. Fumigate the house lightly just before the flowers open and again after the fruits have set, and at all times keep a sharp look out for green and black fly. Ventilate freely on all favourable occasions, but avoid draughts.

MELONS.—Be careful in the watering of these fruits at this early season, and maintain a steady temperature of 65 to 70 degrees at night, admitting a little air daily. Regulate the growths as this becomes necessary, and stop the leading shoots when they reach the top of the trellis. Fertilise the flowers as they appear, and endeavour to set as many fruits as possible at one time, so they may grow away evenly. Sow seeds for succession as recommended.

CUCUMBERS.—Early young plants should now be growing away freely; pinch the leading shoots when they have reached the top, and stop lateral shoots at the first joint as they continue to grow. More moisture may now be given, and light rich top-dressings placed over the roots whenever they appear on the surface is preferable to placing a large quantity of compost around them all at once. A hotbed may now be made ready out of doors, and any strong-growing approved varieties planted on them when ready. Throw the materials, which should consist of equal parts of litter and leaves, into a loose conical heap, and turn two or three times before making up the beds. In the meantime, have the soil made ready and the frames well cleaned and painted if necessary. —F. Jordan, Warter Priory Gardens.

THE FLOWER GARDEN.

HERBACEOUS BORDERS must now be given attention, and the surface soil between the plants should be moved. Choose dry days to carry out such work, and any planting not yet finished must be completed without delay. Keep a sharp look-out for slugs, as they are very partial to the young growths of delphiniums and phloxes at this time of the year. The surface soil of flower beds should also be stirred to give them a fresh appearance and benefit the occupants.

ANCHUSA ITALICA.—The varieties Dropmore, Opal, and Pride of Dover, are handsome subjects for herbaceous borders, and it is a good plan to raise a batch of plants each season to flower the following year. When raised from seeds, however careful one may be in saving them from the best types only, the result will be very variable; so, to procure plants to be relied upon, other methods of propagation must be resorted to. Plants which flowered last season will, in many instances, show no signs of making young growths, but if the roots are quite sound cut them into pieces two inches in length, and insert them in an upright position in pans containing sandy soil; place in a house having a moist, warm atmosphere, and they will soon commence to produce young growths from the top of the cuttings; these growths must be thinned, when large enough, leaving two or three of the strongest. Put them in large 60-size pots and grow them in a cold frame until sufficiently established for planting out in the reserve garden.

SUMMER BEDDING PLANTS.—Many of the quick growing kinds will soon need propagating, and among these are heliotropes, double lobelia, iresine, Coleus Verschaffelti, Salvia splendens, and S. Fireball, verbenas, etc. It is very essential, when raising such plants, to keep them growing without a check until transferred to the open ground, and this can only be accomplished by using a little judgment, for to have plants too forward is equally as unsatisfactory as having them too late. Heliotropes and salvias are especially susceptible to starvation, as they rapidly become root-bound.

CALCEOLARIAS, PENTSTEMONS, AND VIOLAS occupying cold frames, are growing freely, and the first-named will need more space to allow them to develop. Pentstemons and violas can be safely transferred to their flowering quarters should these be available, and the room now taken up by them will prove valuable for other subjects requiring the protection of a cold frame.—T. B. Field, Wych Cross Place Gardens.

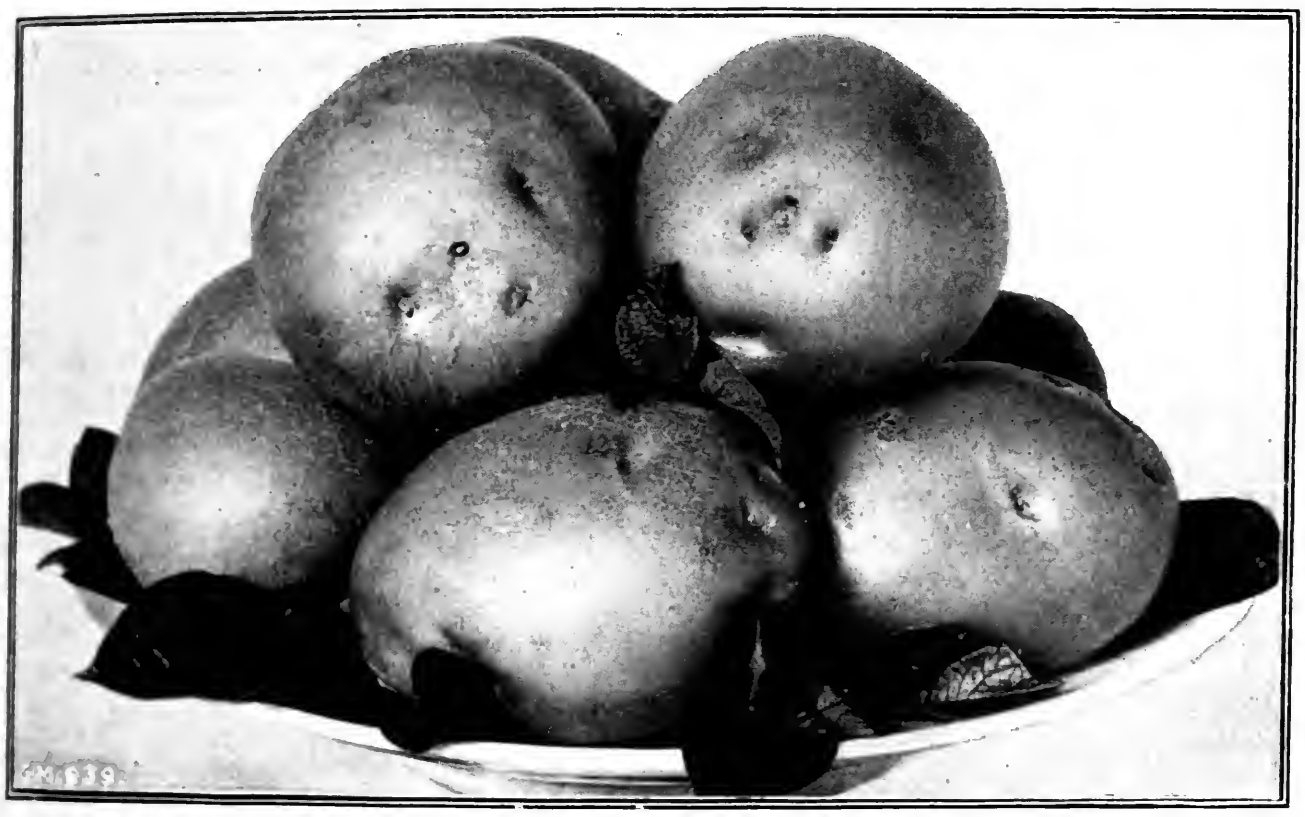
NOVELTIES IN VEGETABLES.

The novelties among vegetables are somewhat less numerous than usual this season, but they are sufficient to give added interest to kitchen gardens in which it is the practice to grow a few new varieties annually in association with others of a similar character that have taken a high position in their respective classes. They should consequently have attention at the present time. With reference to the novelties among vegetables, it may be said that there is a general agreement among cultivators of experience as to the inadvisability of growing novelties on a large scale until they have been subjected to such trial as will enable the cultivator to become well acquainted with their characteristics, and thus be in a position to determine their relative merits for meeting his requirements. With this limitation some at least of the new varieties should be grown each year, for they will give much interest, and some, at least, will be found to possess merits of so high an order as to justify their being assigned a prominent place among the high-class varieties in general cultivation. The following are a few of the more noteworthy novelties that have come under our notice.

The dwarf French beans, which are useful in all gardens, and especially so in those of which the soil is light and warm, include two comparatively new varieties that are especially deserving of attention where the merits of these vegetables are fully appreciated. These are known as Magpie and Sunrise (J. Carter and Co.). The first-named is remarkable for its large pods and great productiveness, and, while of the highest merit for outdoor culture, is admirably adapted for glass culture. The second was raised from a cross effected between Ne Plus Ultra and Carter's Perpetual, is very productive, and has much finer pods than those of Ne Plus Ultra.

Borecoles or kales do not have additions made to them, except at comparatively long intervals, hence a novelty such as Veitch's New Sprouting Kale (J. Veitch and Sons) should have a thorough trial. It is hardy and vigorous in growth; the leaves are fringed at the margin, and the sprouts, which are of excellent quality, are produced in great abundance.

Peas include several novelties of much merit, and brief mention may with advantage be made of the following: Defiance Marrowfat, a second early, and productive variety, attaining a height of four feet, and of excellent quality; and New Distinction, a late blue-wrinkled marrowfat variety of high quality, and equally suitable for exhibition and home supplies (E. Webb and Sons). Early Duke, a first early marrowfat variety, attaining a height of three feet, and producing its handsome, well-filled pods in great abundance (J. Carter and Co). King Edward, an excellent second early variety, about two feet in height, and remarkable for its productiveness, broad, well-filled pods, and the high quality and fine colour of the peas; and Sutton's Longstander, a distinct variety of the Ne Plus Ultra type, but later, more vigorous in growth, and very productive, while the quality is of the highest (Sutton and Sons); and King George, an early wrinkled variety, attaining a height of about 2½ft., and possessing heavy cropping properties. The long curved pods are well filled with large, deep green, richly-flavoured peas (John K. King and Sons).

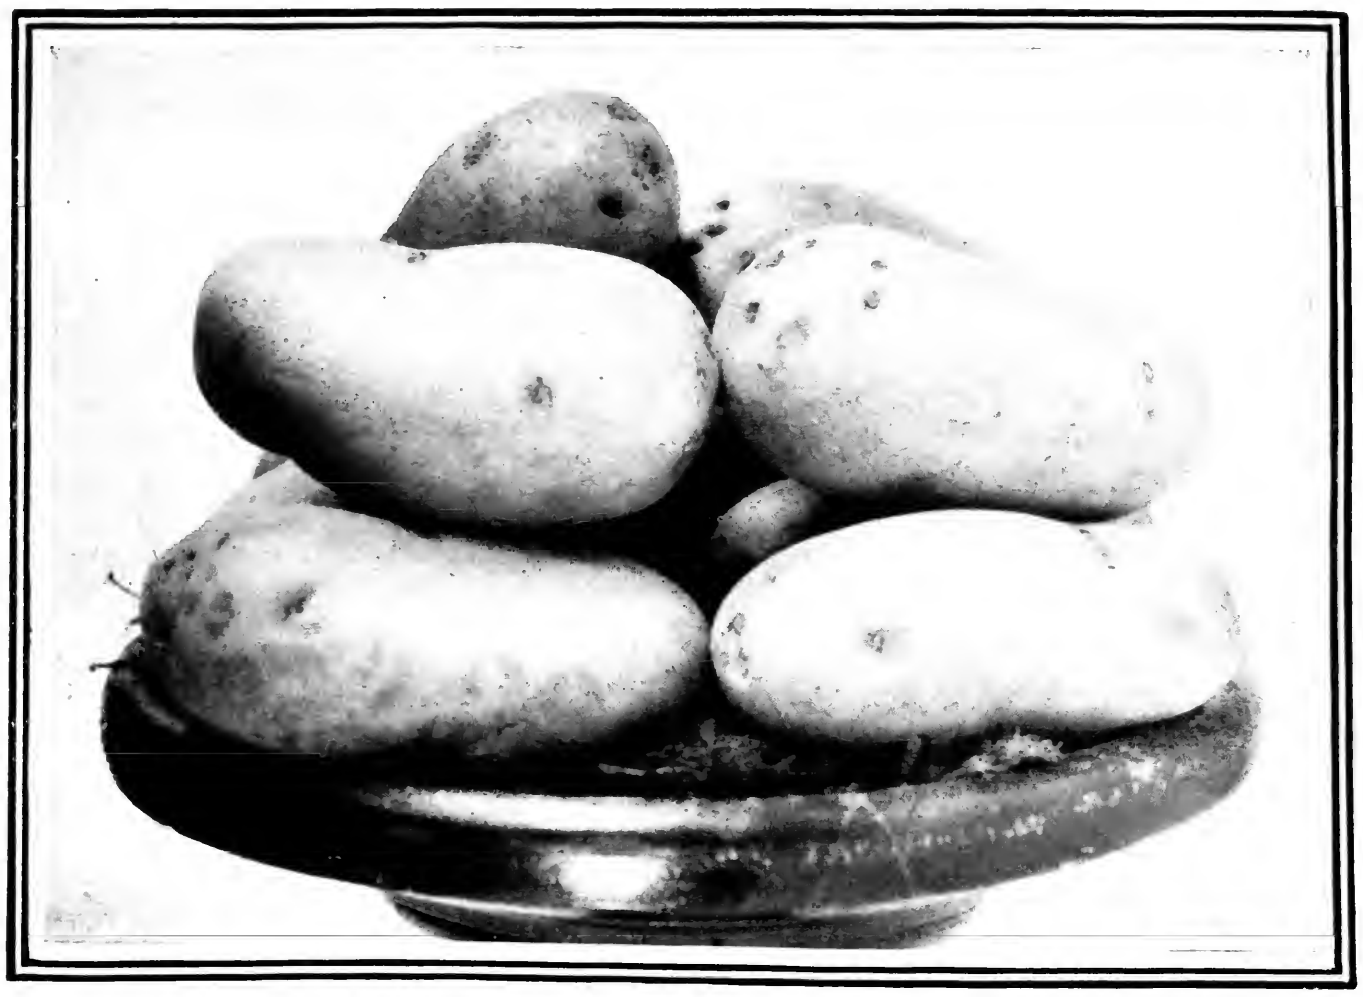


POTATO SUTTON'S BALMORAL CASTLE.
A second early white round variety, very productive and of high quality.

Potatoes of recent introduction include several that should have attention. We mention a few that have come under our notice, but they do not exhaust the list of those which should be generally planted for purposes of trial. These comprise: Imperial Beauty (Barr and Sons), a highly productive variety. The tubers have a smooth skin, and are of a good appearance, and the quality is high. This variety had an Award of Merit made in its favour in the Wisley Trials last year. Balmoral Castle (Sutton and Sons) is a round variety of great merit, and possesses much interest as the first of a new strain of pedigree potatoes introduced by the raisers. It is even more productive than Up-to-Date, the tubers are shapely with shallow eyes; the skin is white, and the flavour excellent. Balmoral Castle, which belongs to the same strain, is a second early kidney, which also is noteworthy for heavy cropping, the fine appearance of the tubers, and high quality. New First Crop (E. Webb and Sons) has the promise of becoming highly popular for first early supplies. The variety is very productive as a first early; the tubers are pebble-shaped, the flesh is white, and the flavour excellent.

Cordyline Doucetti—This is a form of Cordyline or Dracæna australis, and is very distinct and pleasing. It differs from the type in being of a more compact habit, the slender leaves being very numerous. They are, in addition, variegated with white. It is as hardy as australis itself, and is therefore useful in places where the stove kinds might be injured.—W.

Thyrsacanthus rutilans.—Plants grown more or less in standard form show off the flowers of this thyrsacanthus to the best advantage, for being borne on long, pendulous panicles, it is necessary for them to occupy a more or less raised position. Individually the flowers are tubular in shape, and of a deep scarlet or bright crimson colour. If the plants are dwarf, the pots must be raised up in order to show off the flowers to advantage; indeed, for this purpose, I have seen them sometimes suspended from the roof. For general purposes, however, small plants are the best. This thyrsacanthus is easily raised from cuttings in the spring, and the young plants must be grown on without check. They must not be kept too warm during the summer, otherwise red spider is apt to attack the foliage.—T.



POTATO, IMPERIAL BEAUTY.
A handsome and productive kidney potato of high quality. Introduced by Messrs Barr and Sons.

Lettuces of the cabbage type, with finely curled leaves, possess merit that justify their being generally grown for contributing to the summer supplies. Especially noteworthy among the varieties belonging to this type is Evercurled (E. Webb and Sons), a distinct variety, producing hearts of medium size, and of a flavour suggesting a tender endive.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

East Anglian Horticultural Club.

There was a very large gathering of members of this club at the February meeting. The subject for the evening was a lantern lecture by Mr. G. A. Cowie, M.A., B.Sc., upon "The Uses and Abuses of Artificial Manures." The subject was dealt with in a plain and practical manner by the lecturer, and the slides ably depicted the effect of "this or that manuring." As might be expected, all that Mr. Cowie said was received with interest, and a discussion followed, during which it was especially pointed out that before applying artificial manures the grower ought to know something of the components of the soil he is treating. The lecturer was heartily thanked, and suitably replied.

During the evening a large number of new members were enrolled, and Mr. W. L. Wallis, the secretary, was kept busy.

The exhibition tables presented a very attractive appearance with forced bulbs in pots and also in the fruit section. Mr. F. J. Endersby, gardener to J. H. Gurney, Esq., Keswick, was commended for his cyclamen, primulas, and cattleyas. Mr. W. Shoesmith staged a choice bunch of exotic flowers, orchids predominating, whilst the display of carnations put up by Mr. D. Cockerill, gardener to G. E. White, Esq., Eaton, contained blooms as good as one could wish for.

North of England Horticultural Society.

The annual meeting of the North of England Horticultural Society was held at the Queen's Hotel, Leeds, on the 19th ult., under the presidency of Major J. W. Dent, the chairman of council.

The report of the council showed that there had been a large increase in the membership during the past year, the number of Fellows and members being 506, as compared with 414 in the previous year. The scientific and educational work had been carried on successfully, and the exhibitions had been unique as educational factors. The latest plants had been exhibited, while a high standard had been maintained at the shows. Regret was expressed that in spite of the increased membership the accounts showed a serious adverse balance at the end of the year. The council were prepared, if the members so decided, to carry on the society during the current year, and they hoped that by rigid economy and an increased membership a further deficit might be avoided. If by September 30 it was evident that the membership would not be increased to the extent looked for, the council would call a general meeting to consider the position. In order to carry on the society on its present lines an annual income of £500 was needed.

The balance-sheet showed that the expenses had amounted to £829, and that there was a deficit on the year's working of £255. The subscriptions had amounted to £277.

The Chairman, in moving the adoption of the report, said there were certain matters they might congratulate themselves upon, and some points which required their very serious consideration. He thought the steady increase in the number of Fellows showed that the society was attracting attention throughout the North of England, and was doing good work in stirring up interest in horticulture generally. Financially the society had done a shade better than in the previous year, the deficit being £255 as compared with £262 in 1911. They could not, however, continue to face a deficit of upwards of £250 a year. The only way in which the deficit could be obviated was by an increased membership. They could not hope to obtain any material revenue from the shows. All they could hope was that they might pay their way. It lay with the members of the society to say that day whether they thought the society was doing good work, and whether there were possibilities of good work in front of it.

The motion was seconded by Professor R. S. Seton, and a discussion followed, in which Mr. Mansell, Mr. J. Donoghue, and Mr. W. Lawrenson took part. At the close of the discussion the Chairman briefly replied, and the reports and accounts were adopted, and the proposal to carry on the society was agreed to.

It was resolved that a meeting and lecture, with opportunities for the exhibition of plants for certificates, should be held in Leeds on the second Tuesday in each month, except in the months when the society holds its own shows. A spring show will be held in Bradford in March, a summer show at some place to be determined later, and an autumn show in Leeds.

Earl Grey was re-elected president; Mr. Rupert E. Beckett, treasurer; and the Rev. J. Bernard Hall, secretary.

Broughty Ferry Horticultural Association.

The February meeting was held in the Y.M.C.A hall, and Mr. Jas. Bethel presided over a good attendance of members assembled to hear a lecture on "Sweet Peas" delivered by Mr. John Macher, head gardener at Fothringham. In introducing the lecturer, the President took occasion to point out the phenomenal success which had attended Mr. Macher's methods of sweet pea culture during the past two or three years; last year especially this success was very marked wherever he competed. He had won many trophies and some valuable cups at the principal shows in Scotland.

Mr. Macher first gave a short history of the sweet pea and its evolution. His methods of cultivation briefly were to place his order for seeds early in October, and sowing in 5-inch pots from the middle to end of November, plunging the pots in leaf-mould in a cold frame, where the seeds were allowed to germinate and remain throughout the winter, matting them up during very severe frost, and giving air on all favourable occasions.

Holding up some sturdy little plants about three inches high, he defied his audience to produce such specimens from seeds sown in heat in January or February. They might get them as tall, but they lacked constitution, and were destitute of anything like woody fibre which enabled them to start growing immediately after being planted. Planting he performed about April 16 in ground trenched two spades deep, the soil being well mixed with farmyard manure, if possible, in the autumn, when basic slag was added as the work proceeded. In February he advocated forking over the ground, and at the same time giving a dressing of 7lb. superphosphate and 7lb. sulphate of potash to 20 yards' run of trenches, which were 6 feet wide. For planting he favoured double rows, placing the plants 2 feet by 1 foot apart, and, defying superstition, he always planted 13 plants of each variety. Staking he divided into three operations; twigs at first to protect the plants, then three or four feet branches later on, and when they were no longer serviceable he placed others from 10 to 12 feet high, securing the tops to wires strained from each end. He allowed three stems to grow to each plant, all side growths being removed, and the plants never allowed to fully develop their flowers. When the first two flowers on a spike were expanded he cut the spike and let the others develop in water. He believed in cutting such flowers from 12 to 36 hours before a show.

After giving a list of varieties and many hints on staging, he finished up with some hints on judging. A profitable discussion ensued, when many other aspects of sweet pea cultivation were mooted, and all expressed their agreement on the popularity of the lecturer and his subject.

Mr. Alex. Duncan, Carbet Castle Gardens, was awarded the monthly prize for a well-flowered Dendrobium nobile, while the President exhibited a collection of forced narcissi, Tulip Prince of Austria, and Sutton's Pot Myosotis. Votes of thanks to all contributors closed the proceedings.

Dumfries and District Horticultural Society.

A meeting of those interested in the formation of a new horticultural society, to hold an annual open show of flowers, fruit, and vegetables in Dumfries, was held in St. George's Hall, Dumfries, on the evening of February 15. There was a large attendance, and Mr. S. Arnott, Sunnymead, was called to the chair. The draft rules, etc., of the society, as submitted by the committee appointed for the purpose, were considered seriatim, and approved after some alterations had been made. It was agreed that the title of the society be "The Dumfries and District Horticultural Society." The election of office-bearers was then proceeded with, and the following appointments were made with unanimity: President, Mr. S. Arnott, Sunnymead; vice-presidents, from the nursery and seedsmen, Mr. A. W. M'Alister; from the gardeners, Mr. W. Hutchison, The Gardens, Terregles; from the amateurs, Mr. J. Maxwell Gray. Eighteen members of the committee, six each from nurserymen and seedsmen, from the gardeners, and from the amateurs, were elected. Mr. J. L. Armstrong, who has been interim secretary, was elected secretary and treasurer.

Dumfries and Galloway Gardeners' Association.

A meeting of this association was held in St. George's Hall, Dumfries, on February 22. There was a good attendance, Mr. S. Arnott presiding. After the usual formal business, the Chairman called upon the lecturer of the evening, Mr. W. Taylor, The Gardens, Brocklehurst, Dumfries, to give his paper on "Landscape Gardening: Gardens Old and New." Mr. Taylor gave an able paper, covering a comprehensive survey of the different styles of gardens for a long period, and giving a concise summary of this part of his subject. The gardens of the present day and their various styles were also discussed in an impartial manner, and the paper concluded with a number of practical details calculated to be of service to those laying out a garden. These included principles to be followed in the laying out and planting of the grounds and gardens.

Mr. Taylor's paper was an excellent one, and was much appreciated, as was evident from the general tone of the interesting discussion which followed, and was taken part in by several speakers, including the chairman and Messrs. Reid, Hutchinson, Pritchard, Croall, and Nicholson. Mr. Taylor was heartily thanked for his interesting contribution.

Spraying

The question to-day is not "**Shall we Spray,**" as every gardener knows he **must** Spray, but "What machine or syringe shall I spray with?" All the world answers, Use **only** the **reliable** tested

Birmingham Union of Horticultural Societies.

The Birmingham and Midland Union of Horticultural Societies, which was inaugurated in June last, and to which thirteen societies are now affiliated, held their first annual meeting at the University the other evening, with Councillor Neville Chamberlain in the chair.

Mr. William G. Carradine presented the report, which mentioned that nine council meetings and committee meetings had been held, and these had been instructive and helpful, so much so that the means of communication which had now been made possible among the various societies had in itself fully justified the existence of the Union. One of the most important branches of the work of the Union was the prevention of dishonest exhibiting, and the council intended to take active steps in the matter. Arrangements had also been made to provide all affiliated societies with an approved list of lecturers, together with the subjects of their lectures.

On the motion of the President, the report was approved.

Mr. Thomas Silver, chairman of the Union, proposed a vote of thanks to the President for his services, and expressed the opinion that this year the societies would feel the benefit of being amalgamated.

Mr. Chamberlain was re-elected president, Mr. Silvers chairman, Mr. Carradine hon. secretary and treasurer, and Mr. William Marriott hon. auditor.

Mr. Carradine afterwards gave an address on "Some Difficulties of Flower Show Schedules."

Croydon Gardeners' Society.

A subject of great interest to gardeners, especially the hybridist, was considered by the members of this society at its last meeting. The interest in the subject was manifested by the big attendance of members, when the lecturer, Mr. E. J. Allard, from the John Innes Horticultural Institution, Merton, gave a very instructive discourse on "Pollination and Fertilisation." A study of Nature's methods of pollination is a very engrossing one, and one which the hybridist must copy when artificial means are brought into force. Science in horticulture has advanced with good strides, and made what appeared impossibilities years ago actual accomplishments at the present time, hence we have now forms of fruit, flowers, and vegetables, bearing the character of the two parents, obtained with artificial aids, yet differing in the progeny from the parent plants.

Mr. Allard explained with lantern illustrations the process of pollination, and passed on to the different methods of distribution of the pollen grains. Wind and insects play a very important part in this carrying the pollen grains to the receptive stigma of a plant of similar order and fertilisation takes place. Water is also a factor in pollen distribution, and a good illustration is found in the Vallisneria spiralis. The pollen from this plant rises from the flower hidden low in the water and floats on the surface until it comes in contact with the receptive flower also floating on the surface.

Colour attraction to insects was explicitly dealt with by the lecturer; flowers which contain honey are a source of attraction to insects, which, in gathering the honey, transfer the pollen from one flower to another.

Experiments in fruit growing, principally with plums and apples, have proved the great advantage of mixed varieties in an orchard. Some are practically self sterile, and if pollen from another variety can be introduced to the flowers if will ensure a crop. A good many tests have been made in this way by Mr. Allard, and practical information like this was much appreciated by the audience.

The principle of the Mendelian Law is now a governing factor with hybridists, and is proving of great benefits in the science. Demonstrations of this theory were given by the lecturer, and were keenly followed.

With such a subject there were several questions requiring answers, and to each member who raised a query Mr. Allard responded in a generous spirit.

Very unanimous was the hearty thanks of the meeting conveyed to Mr. Allard upon the conclusion of the lecture, and the members appreciated the fact very much that such a college as the John Innes Horticultural Institution is in the neighbourhood.

An exhibition of forced plants was made by Mr. T. Butcher, who staged sprays of double peach blossoms. Mr. T. W. Hayden brought a vase of Sir Watkin narcissus, and two dishes of culinary apples were shown by Mr. W. Paulley. Mr. A. Edwards contributed a dish of pears, all of which lent attraction to the meeting.

Chester Paxton Society.

The second meeting of the session was held recently at the Grosvenor Museum, when a lecture, entitled "Plant Life and Its Place in Nature," was given by Mr. J. D. Siddall, J.P., F.R.M.S., and was fully illustrated with original lantern slides. Mr. John Weaver, of Christleton Hall Gardens, presided over a large attendance of members, who showed keen interest in the subject. At the outset Mr. Siddall clearly described the three kingdoms of Nature—Mineral, Vegetable, and Animal; and explained their distinguishing characters and relations to each other. Proceeding, he showed how plants were dependent upon the mineral kingdom, and how they made from mineral matter the food that was indispensable to the life of animals. Hence, the vital importance of a thorough study of all the details of vegetable life. Beginning with descriptions of some of the simplest forms of living organisms, and concluding with the most highly-specialised plants, such as our forest trees, the lecturer lucidly described the life-history, structure, and functions of many typical examples, which were aptly illustrated by the lantern slides.

The meeting closed by a vote of thanks to the lecturer, on the proposition of Mr. N. F. Barnes, seconded by Mr. Wakefield, and supported by the Chairman and the Hon. Secretary (Mr. G. P. Miln).

FORTHCOMING ENGAGEMENTS.

TUESDAY, March 4.—Royal Horticultural Society; Narcissus Committee meets at 11.30; Fruit, Floral, and Orchid Committee at 12 o'clock; Lecture at 3 p.m. on "The Spring Flower Garden," by Mr. W. H. Divers, V.M.H.; Scientific Committee at 4 o'clock.

Horticultural Club Monthly Dinner and Conversazione at the Hotel Windsor, Westminster; Mr. E. A. Bunyard will lecture on "The Introduction and Development of Some of Our Hardy Fruits," and will illustrate his remarks with lantern slides.

Royal Horticultural Society's Show of Forced Spring Bulbs—two days.

Scottish Horticultural Association.

WEDNESDAY, March 5.—Royal Society of Arts, John Street, Adelphi, W.C.: Lecture on "The Development of Research Work in Forest Products," by Mr. E. Russell Burdon, M.A.; chair to be taken at 8 p.m. by Lieut.-Colonel Sir David Prain, Director of The Royal Gardens, Kew.

Royal Horticultural Society's Show of Forced Spring Bulbs; second day.

THURSDAY, March 6.—Birmingham Horticultural Society; Lecture on "Hardy Annuals, Asters, and Stocks," by Messrs. H. G. Cox and F. Townsend, in the Lecture Theatre, University, Edmund Street at 8 p.m.

Linnean Society Meeting.

MONDAY, March 10.—United Horticultural Benefit and Provident Society.

TUESDAY, March 11. Surbiton Spring Show.

WEDNESDAY, March 12.—Clevedon Spring Show. North of England Horticultural Society's Spring Show, at Bradford.

THURSDAY, March 13.—Torquay Spring Show.

TUESDAY, March 18.—Royal Horticultural Society; Narcissus Committee meets at 11.30 a.m.; Fruit, Vegetable, and Floral Committees at 12 o'clock; Lecture at 3 p.m. on "The Romance of Weeds," by Mr. R. Lloyd Praeger, B.A.; Scientific Committee at 4 o'clock.

SATURDAY, March 29.—Paisley Spring Show.

ANSWERS TO CORRESPONDENTS.

A GOOD SUBSTITUTE FOR STABLE MANURE.—R. F. B., Middlesex: For reasons with which you need not be troubled, I have a considerable amount of planting that I am desirous of completing before the season is too far advanced for such work to be carried out with success. One of the greatest difficulties that I have had to contend with in the preparation of the soil has been the small amount of stable manure available in the district in which I reside. Some of my friends who have good gardens tell me they have used spent hops with the most satisfactory results. I shall be greatly obliged by your informing me whether hops can be used as a substitute for stable manure in the preparation of ground for spring planting, more especially for beds and borders in which roses and choice shrubs are to be planted.—Spent hops are useful for adding humus to the soil and for mulching beds and borders during the summer, but they cannot be regarded as a good substitute for stable manure. The probability is that your friends referred, not to spent hops but to the hop manure prepared and sold by Messrs. Wakeley Brothers and Co., which is a very different substance. Wakeley's Hop Manure, while clean to handle, and in no way objectionable in smell, is so rich in nitrogen, phosphates, and potash, as to afford the various forms of plant life the food essential to their full development. We have used Wakeley's Hop Manure with much success for roses and flowering and other shrubs, and consider it a most useful fertiliser, especially for ground that has to be prepared a short time before the time of planting, there being no risk of injury to the delicate fibrous roots as is sometimes the case with stable manure.

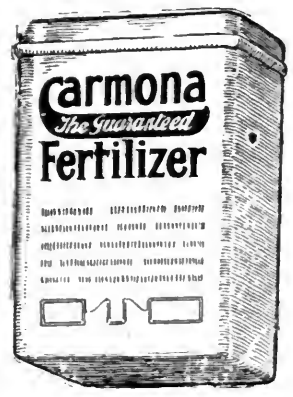
WINTER-FLOWERING PELARGONIUMS.—H. B. B., Lymington: What is the best time to strike cuttings of zonal pelargoniums to produce good plants for winter flowering?—February and March are the best months in which to insert cuttings of pelargoniums when winter flowering is the end in view. Place the cuttings singly in small pots, in sandy soil, in an intermediate house. Pot them as soon as nicely rooted, and at an early date proceed to harden the plants by admitting plenty of air. A pit or frame will afford all necessary protection after this period until the plants have become well rooted in 32-sized pots, when open-air treatment is best. Choose a sunny position, and stand the pots on boards, slates, or a hard ash base. Pinch out the growing point on several occasions to secure bushy specimens, but do not stop the growths later than August. House the plants early in September, and, if possible, allow them a light, airy house where a temperature of from 50 to 60 degrees can be easily maintained through the winter. A dry atmosphere is essential, and the ventilators next the hot-water pipes should only be quite closed during very severe weather.

JIMSON WEED.—H. R. B., Wolverhampton: A friend of mine resident in the United States mentions the Jimson Weed in letters to me. I cannot find what plant it is he refers to under this quaint title, but perhaps you can enlighten me.—The Jimson Weed is Datura Stramonium, an annual plant fairly common in England, and, by reason of its spiny fruits, known popularly as the Thorn Apple.

PRESERVATION OF WOODEN LABELS.—M. W., Coventry: I have an idea that some time ago you referred to a method of dealing with wooden labels in such a way as to ensure their preservation for a much longer period than they usually last. If you will again give the method I shall be greatly obliged.—The life of wooden labels can be considerably prolonged if they are laid in a strong solution of sulphate of iron (copperas) until thoroughly soaked with the liquid. Lay them out to drain, and as soon as dry place them in lime water. The result of these soakings is a chemical action

Guaranteed Gardenalities.

If your Plants could speak they would ask for Carmona Plant Food.



The strength to grow and grow and bloom and bloom is in Carmona. It vitalizes every fibre. Plants cannot do their best if you withhold it. Carmona is the richest Plant Food made, and it is prepared in the only form in which plant foods can be successfully applied to the soil—a fine well-milled powder in which all the ingredients are evenly distributed. Carmona is the consummation of nearly a lifetime's experience in plant foods. It carries the essential nutritive properties for the perfect feeding of plant life. Immediately it is applied to the soil it yields to the plants a liberal percentage of Nitrogen for their immediate use, and gradually, afterwards, Carmona nourishes from its Phosphatic and Potassic reserves. Carmona has come to the aid of the Gardener to help him realise the fullest beauty of which the flower world is so abundantly capable.

A Special Carmona Food for Sweet Peas.

Even the best soils are lacking in a sufficiently high content of the natural foods needed to successfully nourish the modern, highly specialised Sweet Pea. Carmona Sweet Pea Food corrects these deficiencies. It contains, in abundance, those salts so suited to the leguminous nature of the Sweet Pea and to which the plant so generously responds. Carmona-fed Sweet Pea plants immediately assume a sturdier appearance. The leaves pick up and improve in colour, the stem appears in less dire need of support. Buds appear in greater profusion and burst into fine-sized blooms, true to colour. They have much more stamina and remain fresh while other blooms wither off and leave only a seed pod to mark their brief, sickly existence. Start your plants on Carmona Sweet Pea Food—mix it with the soil before you sow, and after, feed them with it every ten days from the time the plants are 3 inches high.

In tins with spoons, **6**d., **1**/-, **2**/**6**.
In bags, 14lbs. **4**/**6**, 28lbs. **7**/**6**, 56lbs. **12**/**6**, 112lbs. **20**/-

A Special Carmona Food for Roses.

The wealth of enjoyment that beautiful roses afford can be yours. The greater the extent to which you cultivate the queen of the flower kingdom, the greater your love for it, the greater will be your appreciation of the wonderful feeding properties of Carmona Rose Food. Carmona-fed roses redeem the glorious promise of their budhood. If Carmona is used Early in the Season new bloom-bearing wood quickly follows the creation of new roots and increased activity on the part of the old ones. The general health of the trees is vastly improved and made disease resistant. To a large extent, by reason of their sound constitution, they are rendered immune from the attacks of aphides which prefer the weaker plants for hosts And those much-prized buds will not appear only to fall off without opening or open in a sickly half-hearted fashion soon to wither, but will come out in a blaze of beautiful colour with full-textured petals displaying all the vigour and beauty consequent upon the trees' robust Carmona-built system. Feed your Roses with Carmona Rose Food now and continue every ten days to apply this true form of Rose nutriment.

In tins with spoons, **6**d., **1**/-, **2**/**6**.
In bags 14lbs. **4**/**6**, 28lbs. **7**/**6**, 56lbs. **12**/**6**, 112lbs. **20**/-

If your plants could speak they would ask for Carmona Plant Food.

Carmona, the guaranteed Fertilizer,

is a highly nutritious all-round plant food upon which the remarkable first prize herbaceous borders grown by Mr. Bouskel, the Chairman of the Hardy Plant Society, are fed. And upon which the wonderful first vegetables shown by the Duke of Portland at the Guaranteed Gardenalities Exhibition in 1912 were fed, You should use it for your vegetables, your herbaceous borders, and to feed all your plants for which there is not a special Carmona plant food. You can buy it from all Seedsmen and Nurserymen in **6**d., **1**/-, **2**/**6** tins with spoons, and in bags 14lbs. **4**/**6**, 28 lbs. **7**/**6**, 56lbs. **12**/**6**, 112lbs. **20**/-

Carmona Plant Foods are simply and cleanly applied with the special measuring spoon supplied in every tin.

Sprinkle it over the soil surface with the spoon supplied.

Fork it lightly into the soil.

Then water it in—that's all.

Send for the New

WEST BROMWICH, STAFFS.

Carmona Plant Foods can be obtained from all Seedsmen and Nurserymen.

which causes the formation of sulphate of lime in the wood tissues, and this sulphate is very insoluble, hence the labels are more enduring than those not treated.

COLLINSIA BICOLOR.—D. W., Ross: I am very fond of the old pale blue and white-flowered annual named Collinsia bicolor, but it is so short lived, as a rule, that I fancy there must be something wrong with my methods. Will you please tell me the best way to manage it?—If seeds are sown in August where the plants are to flower, and the seedlings are thinned to six inches apart, a goodly proportion will survive the winter provided the soil is well drained and not heavy and cold. Sometimes all the autumn-sown seedlings are killed by damp and cold, therefore if a few dozen seedlings are kept, singly, in small pots, in a cold frame, to be planted out in March, disappointment will be avoided. These autumn-sown plants come into flower quite early, and have usually run their course by the end of June, so that if proper arraugements are made their places can be filled by other subjects to give a later display. Spring sowing out of doors should take place as early as the weather permits during March. Choose a sunny spot, sow thinly, and thin out the seedlings quite early.

SWEET PEAS.—J. T. P., Ipswich: Kindly recommend me a handy book upon sweet peas; one dealing with the culture of these flowers for garden decoration and for exhibition, and giving information as to varieties, manures, etc.—"Sweet Peas and Their Cultivation," by C. H. Curtis, contains all the information you will require. It can be obtained from the Gardeners' Magazine Office, 148 and 149, Aldersgate Street, E.C., for 1s. 2d.; on 1s. 8d. (cloth bound), post free.

RINGING FIGS.—"Hibernia" writes: In your issue of February 22 (p. 144), "A. B.," Bradford, remarks that he wishes to take layers from a bush fig tree. Some 13 years ago I desired to convert a fig-house into a vinery, but my employer would not give his consent unless I would guarantee a supply of figs equal to that which he had the previous year. This I did, and, as the method I employed to secure the result may be of service to "A. B." in attaining his object, I have much pleasure in stating it. Of course, it is well known that figs are not difficult things to layer, but the question is: which is the best way to proceed? In order to fulfil my promise, I knew I must get roots on all the principal branches, and not give them any appreciable check when they were removed from the parent plants. This I succeeded in doing by finding sufficient split, 9in. drain pipes, each 2ft. long, and placing them in positions to admit the branches at the desired points. Those split pipes were then filled with a rich, open compost, and the branches ringed just under a joint and buried in the rooting medium. The atmosphere of the house was kept moist as well as the compost, and although I now speak from memory, I think the whole mass of compost was a mat of fibrous roots within a month. I severed the connection with the old plant, carefully preserved the mass of soil and fibres in the split drain pipes, and had them carefully planted in a newly-made border. This done, I took the precaution to guard against a check in case the border should be cold by soaking it with water at a temperature of 90 degrees. This warmth at the root acted like magic on the plants, for they went off into growth with a rush, and perfected more and much finer fruits than they did the year before. So great was the success of ringing with these figs that I have adopted the same means of securing other plants for special purposes by it, and if "A. B." will follow out my plan, he need have no fears. As "ringing" rarely comes into the horticultural vocabulary, I would like to refer to another success I met with in adopting it, and which will show that by employing this method of securing young plants of certain things it is possible to produce what is otherwise unattainable. A number of scarlet chestnut plants were wanted in 5½in. pots, well set for flower, so that they could be forced. Strong growths, with prominent buds, were selected when the wood was fairly firm; these were ringed just under a joint, and had a ball of moss and leaf-soil tied round them and kept moist. These growths were about a month, so far as I can remember, in filling the material with roots, and were then cut from the trees and potted. In due time they were forced, and produced quite a sensation. Other plants could be treated in a similar way, and fine stuff secured for forcing purposes should they be desired, if the method of ringing is adopted. By "ringing," it is meant that about an inch or more of bark is completely removed from the branch or stem that is to be operated upon.

NAMES OF PLANTS.

T. N. G., Tiverton.—1, Cattleya Trianæ, a very poor form; 2, Odontoglossum cirrhosum.

C. L. R., Wolverton.—1, Dracæna Massangeana; 2, D. Goldieana; 3, D. reflexa; 4, D. Baptisti.

W. W. W., Hoddesdon.—1, Pelargonium quercifolium; 2, P. tetragonum; 3, Vallisneria spiralis; 4, Panax Victoriæ.

E. F. S., Chertsey.—1, Ribes sanguinea; 2, Garrya elliptica; 3, Saxifraga Elizabethæ; 4, S. Burseriana; 5, Exacum affine; 6, Acalypha Macafeeana.

THE R.H.S. FORTNIGHTLY SHOWS.

In the report of the R.H.S. exhibition held on February 18, mention is made of the rock garden displays and collections of hardy flowers, which, it is alleged, have become somewhat monotonous, the same style of arrangement and the same kinds of plants being repeated time after time. There is truth in this allegation, although it is assuredly equally applicable to the perpetual carnations, the forced shrubs, mostly of Continental origin, and in summer to the sweet peas. The absolute fact is that very many of the exhibits brought to the Horticultural Hall lack the quality and merit that should mark everything staged at the exhibitions of the Royal Horticultural Society. The aggravating part about it is that whilst much of the Hall space is occupied by exhibits of little worth, the walking space in the Hall is so cramped that visitors find it almost impossible, and certainly very uncomfortable, to struggle round to see what is really worth seeing.

Is it not time the council took steps to remedy a state of affairs that is without doubt giving rise to a spirit of discontent among those who are finding a visit to the show rather a task to be shunned than a pleasure to be enjoyed? Could the shows not be classified in some way? Say, for instance, one meeting a month to be devoted to stove and greenhouse plants, indoor fruits, etc., and the next meeting to outdoor subjects only. As an alternative it might be advisable to limit individual exhibitors to one exhibit per month, also placing certain limits on the extent of each exhibit. Whichever of these courses are adopted, it would to a certain extent reduce the pressure upon space, and if a system of censorship were instituted whereby any exhibitor who staged an exhibit unworthy of the society would be prohibited from exhibiting again for a period of three months, there would be little fear of indifferent plants or produce putting in an appearance. Corrigenda.

Stirchley Amateur Rose and Viola Association.—A new society has been formed to serve the districts of Stirchley, King's Norton, Northfield, Bournville, Selly Oak, and King's Heath, and the first show will be held on July 5, 1913. Mr. W. Ebling, 223, Beaumont Road, Bournville, is the hon. secretary and treasurer.

Bedford Chrysanthemum Show, November 12.

NEWS FROM HEADQUARTERS.

THE EXHIBITOR'S OPPORTUNITY.

The humble copper would not buy your morning paper were not hundreds of thousands of copies sold.

Nor could timepieces be offered at a few shillings were they not manufactured by the tens of thousands, thereby reducing the working expenses to a minimum.

You cannot judge value by price.

It is only the enormous demand for Carters "Exhibitor's" collection of vegetable seeds that admits of their being sold at the price of half-a-guinea, packing and postage free. This favourite collection, with which amateurs are so extraordinarily successful in prize-winning, contains thirty packets of absolutely the best of everything in vegetable seeds. It includes the four finest varieties of Peas, three varieties of Beans, two each of Beet, Cabbage, Cauliflower, Carrot, Celery, Lettuce, and Onion, and one each of Borecole, Brussels Sprouts, Savoy, Cucumber, Leek, Parsnip, Tomato, Turnip, and Vegetable Marrow—all tested seeds from the best re-selected stocks.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Carnations.

To no new or rare plants are the pages of our present issue chiefly devoted, but to flowers that have been cultivated, and highly appreciated, for upwards of three centuries by the flower-loving community, and have received the care and exercised the skill of many generations of florists, whose work, if not always conducted on the lines that we could have desired, is deserving of the respect of those who have an affection for the carnation in its diversity of form and colouring. During the three hundred or more years that carnations have had a place among cultivated flowers in British gardens they have, on the whole, been held in high estimation, the poets have sung their praises, authors have written in advocacy of their claims for a prominent position in the garden, and a comparatively large body of cultivators have given freely of their time and thought to the production of flowers in the highest state of development, and to the creation of forms differing from those already in cultivation either in habit, form, or colour. They have, like other flowers occupying a prominent position, had their vicissitudes, as well as their periods of popularity. These, it may be assumed, have been due, in part, to the vagaries of fashion, and in part to the lines that were now and again followed by different generations of florists who were more or less closely associated with carnations. According to Chaucer, the clove was cultivated in this country in the reign of Edward III., and there is ample evidence that carnations generally were highly esteemed during the reign of Queen Elizabeth. Shakespeare, writing of them, says: "The fairest flowers o' the season are our carnations." Gerard states that he had a yellow carnation in his garden "which a worshipfull marchant of London, Master Nicholas Lete, procured from Poland." Parkinson, who followed Gerard, gives the names of forty-nine varieties that were cultivated during the reign of Charles I., whose Queen was especially partial to flowers. Carnations experienced a setback during the troublous times towards the close of the reign of the last-named King and the Commonwealth, in 1665 Rea stating in his "Flora," that there were formerly many good varieties, of which but few were then to be found in gardens. Concurrently with the decline at that period in the popularity of carnations in this country, their cultivation was taken up in Holland, and Rea states that he knew more than one hundred Dutch varieties, all of them having "fair large and double flowers." From this time they appear to have received greater favour, for in the second edition of his work, published

MR. H. PRENTICE.

some years later, three hundred and sixty varieties are mentioned as being then in cultivation. Passing through a period of two centuries, we find carnations under a cloud, as far as the garden was concerned. There was a large and earnest band of florists engaged in their cultivation, and successful exhibitions were held, but very little was done to increase their usefulness for adding to the attractions of the garden or for the supply of cut flowers for beautifying the home, and for personal adornment. The aim of both cultivators and raisers appeared to be the development of flowers for the exhibition stage, and in this they achieved much success. Necessarily, border varieties obtained no advantage therefrom, and, in course of time, they lost much of their popularity. Recognising the need for reform, the late Mr. Martin Smith, who was for some years president of the National Carnation Society, and raised many beautiful varieties, made strenuous endeavour to bring about a much-needed reform, and succeeded beyond expectations. As the result of his efforts the exhibitions were increased in interest and attractiveness, varieties that thrive in open borders were brought into prominence, and their cultivation greatly increased. Since the period of this reform, more than a quarter of a century ago, the society has largely increased in influence and usefulness, and enjoyed the support of all classes who appreciate the charms of the several sections that have been long in cultivation. Since the initiation of the changes here referred to much has happened in the world of carnations, and, as one result, we have now the perpetual carnations, which have made their way into the majority of gardens and trade establishments, and are now grown in such immense numbers that the figures would be startling were it possible to give a correct record. As the merits of the perpetual varieties had, necessarily, to be determined on lines somewhat different from those which were followed in the case of the border and show varieties, it was seen that a special code for judging new varieties should be prepared. The National Carnation and Picotee Society was invited to take the matter in hand, with the co-operation of some of the leading authorities on the perpetual varieties. Unfortunately, the existing society failed to recognise its responsibilities, and no steps were taken in connection with it. Accordingly a society in the interests of the perpetual carnations was formed, and it has done such excellent work as to fully justify its existence. The older society, in the special sphere of its activities, has also done, and is doing, good work, and this matter is not referred to because of any laxity on the part of either body. We refer to it because of the undesirability of splitting the varieties of any flower into two or more sections, and setting up a society for each. What we might have had, and, indeed, should have had, is not two societies, but one, and that a National Carnation Society which would unite in the bond of membership all who are actively interested in the flower. We may, perhaps, have some day a society such as the one we have in our mind, but for the present we shall have to be satisfied with the existing state of

things, and do all that is possible to promote the development of the several classes as garden flowers. In this connection it might be well to consider whether it might not be possible to amalgamate, not the two societies, but the border and perpetual carnations, with a view to increasing their value for decorative effect in the open. It would unquestionably be an immense advantage to considerably extend the season of the border varieties, and increase the hardiness of the perpetual section, and render their flower stems more rigid. What is greatly needed for the further popularisation of these flowers for outdoor culture is a race that will bloom freely throughout the summer and autumn, and be so hardy as to be able to successfully battle with the climatic conditions that obtain in this country. Seeing what has been accomplished in connection with carnations and some other flowers that might be mentioned, a consummation so much to be desired should not be regarded as impossible.

Mr. H. Prentice.—The subject of our illustration belongs to the younger generation of head gardeners, who are ably carrying on the traditions established by what is known as the old school. Mr. Prentice started seriously on his gardening career at Hewell Grange, the Earl of Plymouth's fine Worcestershire seat, and it was in those early days that he learnt to realise that important as the glass department may be, the care of the outside garden is even more so, and these precepts he has put into practice since he became a head gardener. After remaining at Hewell Grange, the young gardener removed to the Pastures, near Derby, where he stayed two years before moving again to the beautiful home of Madame Patti (Baroness Cedérstroom) where he had charge of the winter garden, conservatory, and plant houses. The next change was to a foremanship at Lord Joicey's establishment at Gregynog Hall, Montgomery, under Mr. J. Jackson, of whose tuition Mr. Prentice speaks very highly. The subject of our illustration became head gardener to W. J. Gordon-Canning, Esq., at Hartpury House, near Gloucester, about seven years ago, and during that period he has established a reputation for himself as being an excellent gardener and capable organiser. A believer in education, Mr. Prentice impresses on his subordinates the importance of taking fast hold of instruction, and, though he is too modest to talk about himself, the garden under his charge bears ample testimony to his capabilities. In short, Mr. Prentice is a worthy example of a capable, well-informed, and intelligent young head gardener, and while this type remains, gardening will not go far wrong.

Testimonial to the Rev. W. Wilks.—Mr. W. A. Bilney, J.P., asks us to announce that the fund for the testimonial to the Rev. W. Wilks—who, as our readers are aware, has just completed twenty-five years of service as secretary of the Royal Horticultural Society—will be closed on Tuesday, March 25, hence intending subscribers are requested to send their contributions at an early date to the London County and Westminster Bank, 173, Victoria Street, Westminster, S.W.

The Davidson Annual Cup.—The Council of the Royal Horticultural Society have accepted the offer of an annual silver cup from E. H. Davidson, Esq., of Borlases, Twyford. In 1913 it will be awarded in open competition at the Spring Show at Chelsea, on May 20 to 22, for the "finest cattleya, not a hybrid, in the show." The decision of the Council will be final, and the cup may be withheld altogether at their discretion. The Council will not award the cup unless satisfied that the exhibit is, in the main, due to the work and capability of the exhibitor or his employees. The Council may reserve decision till the third day of the show.

Dynamite in the Garden.—It is very doubtful whether dynamite will ever take the place of the spade in gardening, though it may well supplement the work of the plough in agriculture. Experiments are being conducted in several parts of the country. Dr. Herbert Durham has recently worked his garden at Hampton, Hereford, with the aid of cheddite, a form of dynamite. The explosive was placed in holes 3ft. deep, and though the garden is near the house, and the soil dealt with only a few yards from a glasshouse, there was little concussion, and no damage, nor was the soil forcibly thrown into the air. The soil was moved to a depth of six feet by the explosive, and it has been estimated that in a couple of hours the cheddite did as much work as a man could have done in a fortnight, and loosened the soil to a greater depth. It is anticipated that the gases generated would kill insect pests, and add to the fertility of the soil.

Rose Dell at Kew.—A considerable amount of renovation has during the present winter been done in the Rose Dell, which was formed sixteen years since, and is so charming a feature of the Royal Gardens, Kew. The soil in some parts of the dell has been renewed and advantage has been taken of the opportunity thus afforded for adding a selection of the best and most distinct of the new rambler roses to the collection already established.

Kentish Fruit Research Station.—The scheme for a fruit research station in Kent, for which the Board of Agriculture has promised an annual grant of £500, has taken definite shape. The site selected is at East Malling, near Maidstone, and covers a little over 22 acres. For the purchase of the land and the erection of the necessary buildings £2,500 is estimated to be required, and the Kent County Council have agreed to contribute £1,500 on condition that the balance is forthcoming from either the County Council of Surrey or Sussex, or from some other sources. Under the scheme the land will be conveyed to the County Council, or County Councils, and will then be let to the Governors of the South-Eastern Agricultural College, Wye, upon an agreement that they will expend the balance of the fund in erecting the necessary building and setting out the land. The college will be responsible for carrying on the work of the station.

Gardeners' Royal Benevolent Institution.—The following letter has been sent to 8,000 gardeners in Great Britain by Sir Harry Veitch, inviting them to become subscribers to this charity, of which he is treasurer and chairman of committee: "I am very anxious to induce more of my brother gardeners to give a generous support to the Gardeners' Royal Benevolent Institution, which is doing such admirable work in providing, so far as its means allow, annuities for those who are necessitous and past work (also their widows), also in giving assistance to deserving cases in temporary distress. I appeal to you, therefore, to become a subscriber should you not be one already, and, if you are a member, then to do your utmost to induce others to follow your example. It is very sad to think how many deserving applicants have to wait, sometimes, for years, for that help of which they stand so much in immediate need, and which they cannot receive at once in consequence of the want of sufficient funds, and it is in order to try and remedy this that I now make my appeal to you. I venture to point out to you that if you may never have to seek its help, you will be contributing and doing all in your power to induce others to join be assisting those who have been less fortunate than yourself in the battle of life. The head gardeners of Great Britain are said to number upwards of ten thousand, and it is indeed sad to think that of that number only about one-tenth are at present supporters of an institution the work of which is carried on for their special benefit. I shall be most thankful to you if you will now help to remedy this state of affairs."

Trial of Spraying Apparatus at Wisley.—The Council of the Royal Horticultural Society are arranging to have a trial of spraying apparatus and outfit this spring, and have fixed Wednesday, April 23, for that purpose. Makers are accordingly invited to send their apparatus to Wisley for this trial. Their own assistants can be present to explain and to start the machines, etc., that they may appear to the best advantage from the points of merit claimed for them.

Cyclamen Flowers in Decoration.—In the course of a paper, read by Mr. F. E. Peacock at the monthly meeting of the Torquay Gardeners' Association, special attention was directed to the value of cyclamen flowers for decorative purposes. Mr. Peacock said that many cultivators failed to secure the lasting properties of cyclamen flowers when cut through adopting a wrong method of procedure. Instead of their being cut, they should be pulled from the corm, as, when cut, the stem decayed, and caused the corm to decay. After being pulled away from the corm about an inch should be cut from the base of the stem, and the stem then put in warm water as deep as it would permit. They should remain in the water about half an hour, when they can be arranged in vases and other receptacles, as may be desired. Mr. Peacock said that in his experience the flowers that were put in cold water when gathered would flag in a short time.

Pruning and Planting of Fruit Trees.—With reference to these important operations, Mr. A. D. Richardson writes: In Mr. Spencer Pickering's lecture on this subject at the Royal Institution, as reported in the Gardeners' Magazine of March 1, we are told that in planting trees received from the nursery "it could make little or no difference to the future welfare of the tree whether the ends of the old roots were trimmed, or left jagged and torn, nor whether these roots were carefully spread out, instead of being huddled into the hole prepared for them; for it was the new rootlets which were to be formed, and not the old ones, on which the future life of the tree depended." If it be the case, as Mr. Pickering states, that careless planting is attended with as good results as the most careful, in the case of fruit trees, how is it that in the case of coniferous forest trees failure is so often due to careless planting? Illustrations have repeatedly appeared in forestry journals of plants which had failed through having malformed root systems, due to bad planting, both in the nursery and in plantations, and if failure can be traced to careless planting in their case (and I don't think there can be much doubt on this point, although I do not for a moment commit myself to the opinion of some of our non-practical lecturers on forestry that notching is responsible for it, for they don't know the difference between a good notch and a bad one), how is it so different from that of fruit trees? Why do these

plants not form a new root system when they are maltreated in planting, just as fruit trees do? It would be interesting to know if Mr. Pickering can give any explanation of this.

Torquay Sweet Pea Society is the latest addition to the list of societies exclusively devoted to the cult of the sweet pea. The first exhibition under the auspices of the society will be held on June 25, and the schedule of prizes includes thirty-one classes.

Miss Ethel Sargent, F.L.S., who has done excellent work in connection with plant anatomy and embryology, is to be President of the Botany Section at the meeting of the British Association, which takes place at Birmingham in September next. Miss Sargent will be the first lady to preside over a section of the British Association.

Pergola for Vines.—The need for a better means of exhibiting the collection of vines (Vitis and allied genera) at Kew has, according to the "Kew Bulletin," long been felt by the authorities. Ever since the reorganisation of the Arboretum by Sir Joseph Hooker, about forty years ago, they have been grown on a curving line of iron posts near the North Gallery, where they have had to be treated as bush rather than climbers; being pruned back every winter and the shoots being shortened once or twice during the summer. A pergola of the same type as the Rose Pergola has now been provided for them. It consists of two rows of iron uprights connected by flattish arching rods and linked together lengthwise by chains. The perloga is about 500 feet long, 11 feet wide, 10 feet high, and about 12 feet between each pair of uprights. It runs parallel with the Acacia Avenue, between it and the site of the Refreshment Pavilion.

A New Remedy for American Gooseberry Mildew. — Mr. T. Thorne Baker is, we learn, testing the effects of certain of the sulphur bacteria upon the American gooseberry mildew. This destructive fungus has been killed by Mr. Baker by applying to it, on the infected twigs, a sulphide solution, which is afterwards decomposed by the application of a high frequency electric discharge. The nascent sulphur produced under the electrical influence immediately destroys the red form of gooseberry mildew. More extensive tests are to be carried out next autumn, together with experiments in which other bushes will be sprayed with sulphur-bacterial solutions.

Floral Zygomorphy. — To the monthly meeting of the Royal Society of Edinburgh Mr. J. McLean Thompson contributed a paper on the initiation of staminal zygomorphy. In the course thereof he directed attention to the fact that a study of the very young buds and expanded flowers of Greyia Sutherlandi showed that in all parts of the flower zygomorphy was initiated, but it was not maintained. In the case of the stamens the filaments did not attain the maximum length simultaneously; but sooner or later they all attained the maximum length, and when this stage was reached the anthers dehisced. It was shown that the lengthening of the filaments was due to the elongation of the cells, the number of which remained the same from an early development stage up to the perfected condition.

MAZUS RUGOSUS.

A small growing plant with flowers of a rose-purple colour. A.M., R.H.S., and Hardy Plant Society, March 4. The Wargrave Plant Farm, The Arcade, Liverpool Street, E.C.

DWARF FIBROUS-ROOTED BEGONIAS.

When planning the floral arrangements for beds and borders for the season, one is sometimes at a loss to find an adequate and effective edging plant to prevent a clashing of colours. To anyone who has not become acquainted with the newer forms of the dwarf, fibrous-rooted begonia for this purpose, I would strongly advise their adoption, for, not only are the flowers very freely produced, and able to withstand adverse changes of weather almost unharmed, but the foliage of many of them, being of a bronze or metallic hue, makes a telling display at all times.

For small beds a single row of plants forming the outer belt may be ample, but for others of considerable area, or for wide, lengthy borders of plants, two or more lines will be requisite, and these should be planted about eight inches apart, so that by the early part of August the intervening spaces are filled. As for the genus in general, a generous soil is necessary, and if the natural medium is inclined to retentiveness, sand, leaf-mould, or well-decayed manure, used separately or mixed together, and applied where wanted some time previous to planting, will answer. A similar mixture, applied as a mulching upon the surface, will induce free rooting, and prove an antidote to drought.

Raising the Plants.

It is obvious that, being fibrous-rooted, the plants must be raised from seed each year; but this is not a troublesome process compared with the returns, where a steady, humid temperature of from 60 to 70 degrees can be maintained for a few weeks. Like its tuberous-rooted compeers the seeds are dust-like, and require a very fine and well-prepared soil to aid germination; while a close-fitting case or hand-light placed within a heated house will be found conducive to success. Failing a house, a quantity of fermenting material (fresh leaves and stable litter in about equal parts) should be prepared by being well mixed and occasionally turned, to dispel rank gases, after which it may be formed into a suitable-sized heap and made quite firm. Upon this the hand-light or other contrivance may be placed, and the bed of soil to a depth of two or more inches be put upon the manure and made level and smooth to receive the seeds. If moderately moist, water may be withheld; but if otherwise a sprinkling should be given a few hours before the seed is sown. When sowing, distribute the seeds as evenly as possible, and follow by pressing it down with some plain, smooth article to which the seeds will not adhere. Place on the cover, and use shade until germination begins, when both light and air must be admitted very cautiously, and sunshine must at all times be excluded until the second pair of leaves have formed. This stage attained, transplanting must be carried out, using good friable and warmed soil, and giving shade through the brighter portion of each day until the plantlets are again established. After this growth will be rapid, and as a consequence less heat is necessary, leading to the usual hardening off preparatory to planting out in due course.

Varieties.

These are fairly numerous, varying slightly in height and compactness of growth, while the colouring of the flowers is mostly of the crimson and pink shades, the former being as a rule most reliable where strict adherence to a particular colour scheme is desired. As already stated, the beautifully marbled foliage is very striking, more especially so when bespangled by dew, or rain showers, the drops of moisture scintillating in the after sunshine in a manner certain to find appreciation. Last season, which was acknowledged one of the dullest on record, a broad band of Carter's Crimson on each side of a central walk some fifty yards in length, continued in bloom from the middle of July until November, and at no period was there any lack of display; while the handsome foliage made a most effective groundwork or setting to the crimson brilliance when most other kinds of edging plants presented a woe-begone appearance. Late in autumn many of these plants were carefully lifted and used in diverse ways for room and table decoration, thereby fulfilling a dual purpose.

JAMES DAY.

TOMATOES FOR SUMMER SUPPLIES.

Tomatoes are of so much value as articles of diet during the summer months that to many it must be a great source of satisfaction that liberal supplies can be produced without any special difficulties having to be surmounted. As in the growth of other garden crops, it is not everyone who achieves a full measure of success, but the details are simple enough, and when failures occur they are, in the majority of cases, due to their not being properly understood. The chief points in the culture of tomatoes are to have strong plants, to avoid a compost containing a large proportion of nitrogenous manure, to repress the growths not required for fruit bearing, and to assist the plants with rich top-dressings or liquid manure when carrying heavy crops of fruit.

Whether the tomatoes are to be grown under glass or in the open, a beginning should be made at once, as there will then be no occasion to grow the young plants in an unnecessarily high temperature to have them of a suitable size for transferring them to the pots in which they are to fruit, to inside borders, or to a warm border outside at the proper time. Sow the seed thinly in five or six-inch pots filled with a light, sandy compost, cover lightly with the mixture, give a watering through a fine rose, and place in a structure in which the temperature ranges from 65 to 70 degrees. It matters not whether the seed pots occupy a light or dark position previous to the germination of the seeds, but immediately the seedlings make their appearance above the surface they should be placed where they will be within a short distance of the glass, and enjoy a free circulation of air. When the plants are about two inches in height put them singly in three-inch pots, and place them in a rather shady position, where they should remain for a few days until they have recovered from the check received.

From the period of the plants becoming established in the small pots until the time arrives for transferring them to their permanent quarters, a comparatively small house or spacious pit will afford the most suitable quarters. A temperature of about 65 degrees should be maintained, and the structure be freely ventilated. In bright weather an increase of ten or more degrees may be allowed during the day, and in cold, dull periods it will be well to increase the fire heat instead of reducing the ventilation, to prevent the temperature falling below that which is here advised.

The proper time for repotting the plants will be when they have well filled the pots with roots, and the first shift should be into others six inches in diameter. The proper time for shifting those to be grown in pots under glass into pots nine inches in diameter is when they have well filled the six-inch pots with roots. The most suitable compost from the time the young plants are potted off singly until they receive their final shift is one consisting of turfy-loam four parts, and leaf-mould or manure from an old hotbed one part, with a liberal proportion of coarse grit, the exact quantity of the latter being determined by whether the loam is light or heavy. The pots should be efficiently drained and stood on the surface.

In the case of tomatoes planted out under glass the bed should be comparatively shallow, and from twelve to fifteen inches may be mentioned as a suitable depth. When the beds are of sufficient depth to allow a wide range for the roots the growth is usually too robust to admit of the production of heavy crops of high quality, and it may become so soft as to be a ready prey to various fungoid pests. The aim should be to encourage a firm, short-jointed growth, and, when a heavy crop of fruit has been set, to assist them with a top-dressing of some suitable artificial fertiliser, or supplies of liquid manure. Whether the plants are trained to a trellis or grown in beds on the floor of the house, training as single cordons is preferable. In the former case the plants should be planted about two feet apart, and in the latter the best results will be obtained by arranging them two feet apart in rows with three and a-half feet spaces between them. Pot culture is preferable, although involving greater attention and more work.

In outdoor culture the best results are obtained by training the plants to a wall with a south aspect, and failing an available wall space a warm border should be taken advantage of. In favourable seasons excellent crops may be obtained from plants in the open quarters. A forking over of the border will be necessary, and if the soil is very poor a light dressing of a phosphatic manure, such as superphosphate of lime or bonemeal, may be applied. Strong plants in six-inch pots should be bedded out. Against a wall two feet will be a good distance at which to put them apart, and when in borders and open quarters allow the same space in the rows, which should have three-feet spaces between them. Grown as cordons all the side growths must be nipped off as they appear, and those grown away from walls should have the top of the stem pinched out when four clusters of fruit have set.

The varieties available are so numerous that in making a selection those who are not well acquainted with tomatoes experience some difficulty. Even those who have considerable knowledge find the task otherwise than easy, and I shall not do more than state that, in my practice, I have found Carter's Sunrise, Sutton's Best of All, Webb's New Emperor, and Dickson and Robinson's Moneymaker of great excellence for culture under glass. Out of doors Carter's Sunrise and Sutton's Earliest of All have been most satisfactory with me.

PRACTICAL CULTIVATOR.

THE NEWER BORDER CARNATIONS.

The great extension of the cultivation of perpetual-flowering carnations has reacted upon border carnations in a marked degree, and given a very distinct impetus to their use in the garden. With the popularity of the former has come a better method of exhibiting the latter, and it is now quite the thing to exhibit flowers in vases, with long stems, and sufficient "grass" to produce a more natural and artistic display than is possible when individual blooms are placed on the show board. We do not decry the show board method, but we feel quite sure that flowers in vases add materially to the attractiveness of an exhibition, and are most likely to induce visitors to take up the culture of border carnatons.

We again give some illustrations of first-rate varieties. Droitwich, raised by the Rev. C. A. Gottwaltz, and distributed by Messrs. Arthur R. Brown, Lim., King's Norton, Birmingham, was finely shown by the latter last season; it is a white ground fancy, with rosy-red markings, and has a very refined and pleasing appearance. Mrs. G. Marshall is one of the finest of crimson selfs, and the vase figured represents the blooms which won premier honours at the National Carnation Show in July last, for Mr. J. H. Lakeman, of Thornton Heath, in an open class.

Bob Acres and Jean Douglas are two fine additions to the list of scarlet selfs, the former, as illustrated, won for Mr. James Douglas, Great Bookham, the premier award for a vase of one scarlet self in July last, while the variety named Jean Douglas is a deep, yet brilliant, scarlet self of splendid form and substance. It gained an Award of Merit at a meeting of the Royal Horticultural Society held on July 2 last when shown by the raiser Mr. James Douglas. John Ridd, yellow ground, marked with bright rosy-red, promises to be one of the finest of fancies, and is one of Mr. Douglas' seedlings, and gained an A.M. on the same occasion as Jean Douglas.

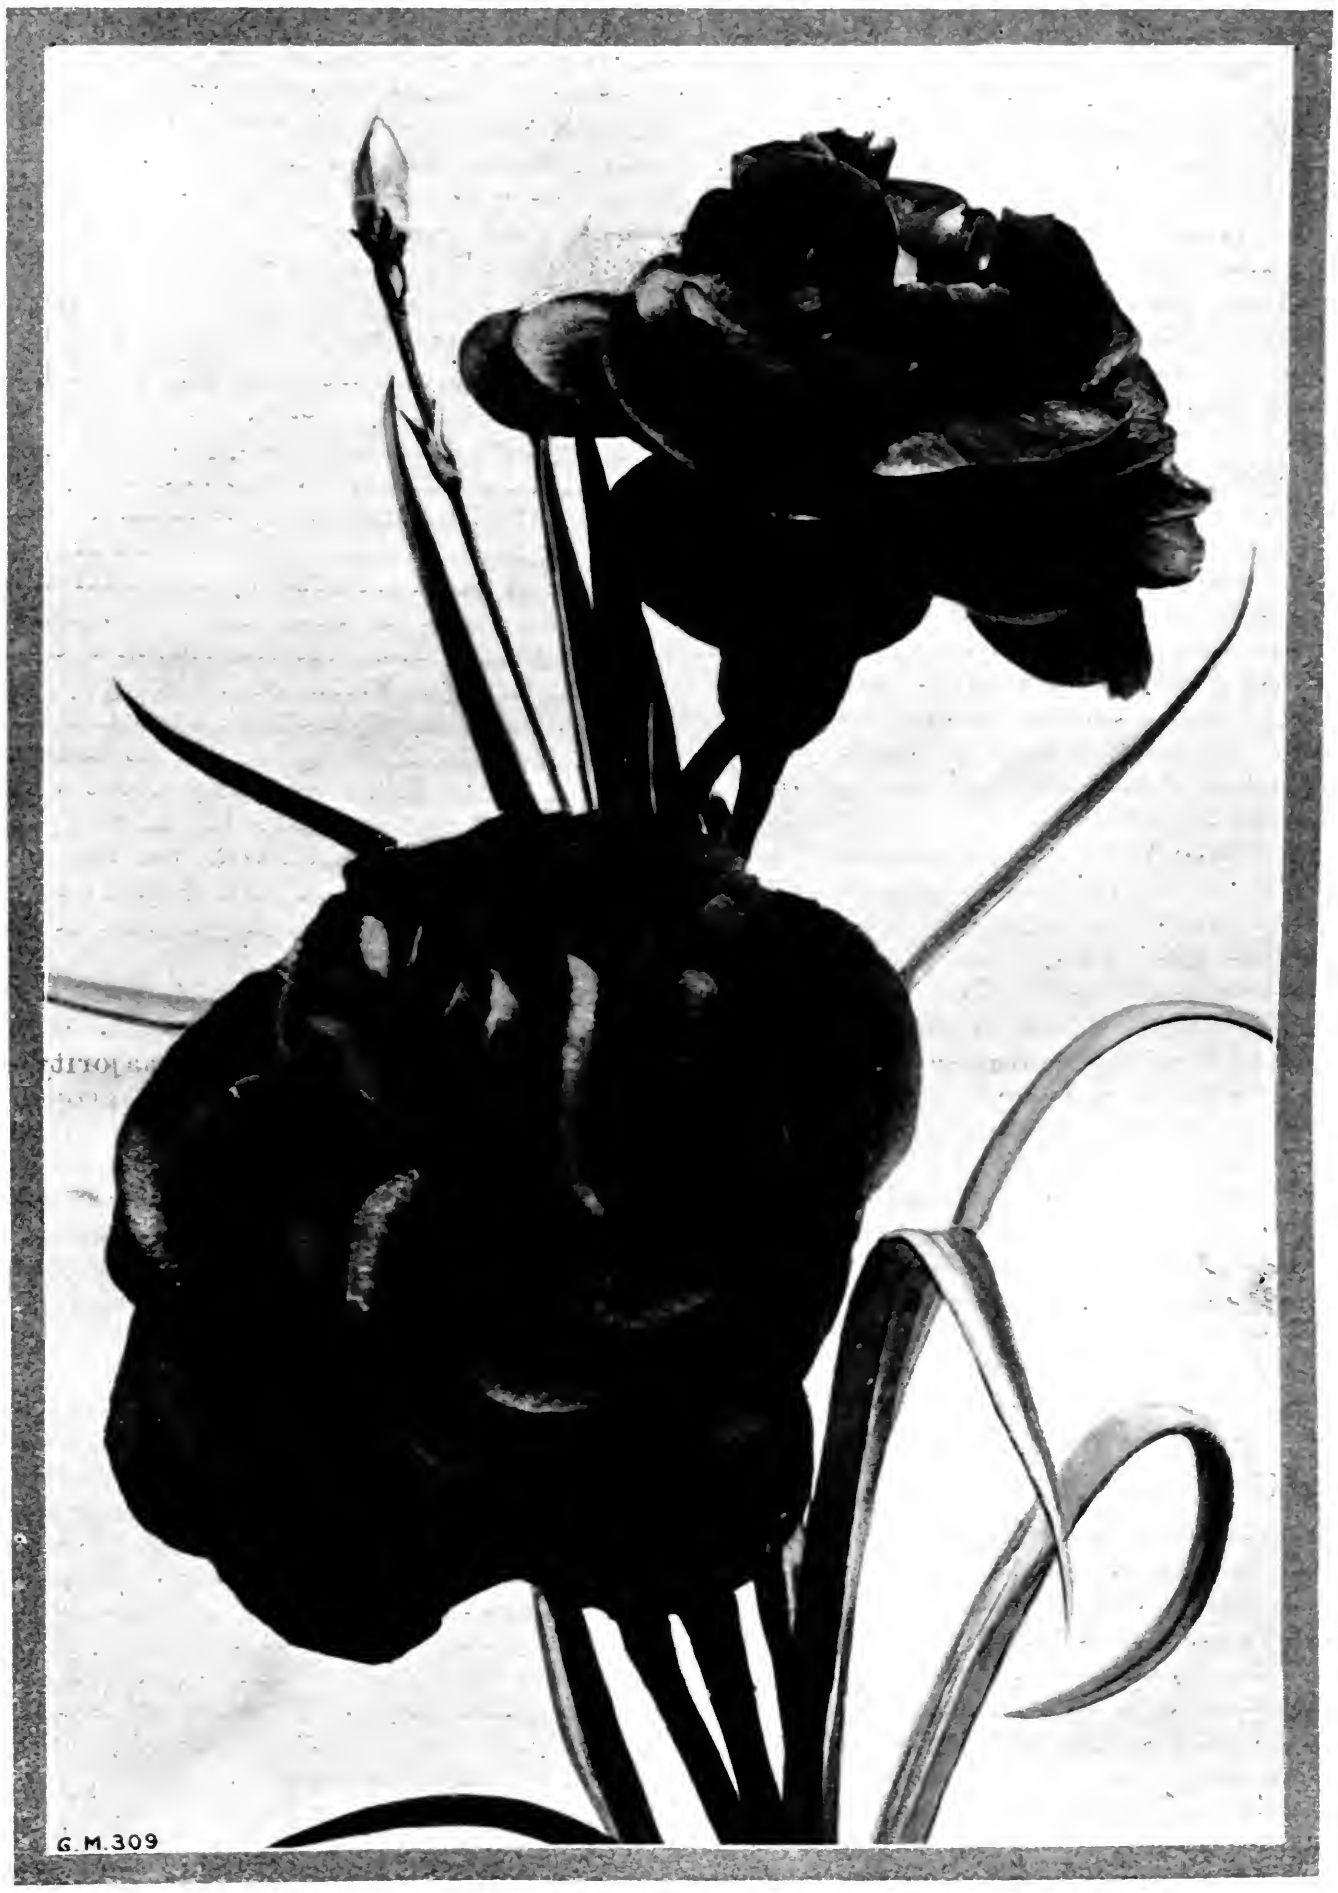
Mr. Charles Blick, Hayes, Kent, has scored with Queen Mary, a lovely salmon-rose variety that is especially fragrant. King George is a fine pure white self from the same raiser, and both King and Queen have gained the A.M. of the R.H.S. Caradine, a yellow ground fancy, with heavy crimson markings, is a Hayes variety that attracted a great deal of attention at the international Horticultural Exhibition, while Cyclops, orange, shaded with scarlet, gives a very distinct and effective bit of colouring, and is also one of Mr. Blick's novelties, as is Attraction, a champion pure white self.

Messrs. A. R. Brown's Begonia is a quaintly-named salmon self of great substance and beauty, while their Eureka, a grand rose self, and Royal Velvet, a very distinct deep imperial purple self, is another variety of great prominence and one that is almost unique in colouring.

Eulalia japonica variegata.—There are three distinct varieties of Eulalia japonica, or at all events, the grass commonly grown under that name, but which is now by our botanical authorities referred to as Miscanthus japonicus. Of the three varieties there is the one at the head of this note, whose long, gracefully arching leaves are freely striped with white, next, gracillima, with much narrower leaves, in which the white marking is limited to the midrib, and lastly, zebrina, whose leaves are barred transversely with cream. They are all hardy, but variegata is largely grown in pots for various decorative purposes.—W.

BORDER CARNATIONS FOR CUTTING.

Seedling carnations afford such a wealth of cutting material and such brilliant colours that their culture should find greater favour. Carnations are lasting, and, provided they are tastefully arranged, they are most pleasing. I am aware there are some slight objections to seedlings, and the most important one arises when there is a high percentage of singles in the bed. On the other hand, I have made excellent use of distinct colours for dinner-table decoration, using freely some of the finer grass with the flowers. Those who have to vary their floral work daily can make good use of the single varieties, and it is surprising what a pleasing effect they have when lightly arranged, and when colours that show up well under artificial light are selected.



CARNATION JEAN DOUGLAS.

A very finely-shaped self border variety, of brilliant scarlet colouring. A.M., R.H.S., July 2, 1912. Mr. James Douglas, Great Bookham.

Selecting Seedlings.

Those who raise their own seedlings will have observed that a goodly proportion of the plants are always more advanced than the others, and here much care should be exercised, as often these have a much stronger or thicker leaf growth; but they are rather misleading, and should be rejected, selecting those of less robust growth, as these mostly will be doubles and of the best quality. I have noted that a large percentage of yellow varieties are obtained from the smaller or backward seedlings in the seed pan.

For many years I relied upon the border varieties for house decoration, but found it important to obtain seed from a good source. If this is done there will be a small percentage of useless flowers. We found, however, that the "grass" was useful, for when the useless sorts were discovered all flower spikes were removed from the plants, and this gave us abundance of foliage for use with the good blooms.

Some of my readers may remark that the border varieties are much inferior to the Malmaisons as decorative flowers. This is simply a matter of taste. I always found that by careful selection of colours we could get a much lighter and prettier effect from the seedlings. From seedlings the grower has much pleasure as the flowers open; there are frequently colours that are

wanting in the other forms grown under glass, and it is an easy matter later on to propagate and retain a good variety.

Sowing and Transplanting.

The sprng months form undoubtedly the best time to sow, and March, April, or May may be selected, according to the means for growing the plants. May might be considered late, but I have, at times, found it advisable, with every inch of glass in use, to defer sowing till May, and by so doing give the seedlings more room and attention. There is no gain whatever—indeed, there may be loss—by sowing early and allowing the seedlings to remain too long in the seed pans, for if they become drawn they rarely grow well. Another point to be considered is the after-culture of the seedlings; I mean as regards the date of sowing. In a very exposed garden, with a wet clay soil, I have varied the culture somewhat by sowing in June or July in cold frames, pricking the seedlings off when large enough to handle, and growing them in cold frames all through the winter, planting out the seedlings the following spring. Of course, this is rather exceptional treatment, but it was necessary in a cold soil in a northern county.

Seeds sown in the early spring in a warm frame soon germinate, and the seedlings should be placed as near the glass as possible as soon as above ground. I am in favour of a little warmth at the start to assist germination, but excess of heat or lack of ventilation means weak plants. Later on, for May sowings, a cold frame, kept close till the seedlings appear, will suffice, provided the pans or pots are placed on a well-drained surface or on boards. In all cases water sparingly at first.

Provide good turfy loam that has been stacked some time. Get loam free from wireworm, as this pest is one of the worst enemies the carnation has to contend with; when stacking the loam place layers of fresh soot between the turves. Loam deficient of grit should have a liberal addition of old mortar rubble. Secure ample drainage in the seed pans, and cover the seeds very lightly after sowing, and place a sheet of glass over the pans to check evaporation. Boxes of a shallow build do well for the seedlings, or they may be planted in pans or temporary shelters until large enough to plant out in their permanent quarters.

Preparation of Beds.

The beds should be prepared some little time in advance of planting. The seedlings will be large enough when four or five inches high, and I prefer early planting. Plant firmly, fifteen to eighteen inches apart, and eighteen inches between the rows. June, July, or August are good months for planting, but, of course, the date will be governed by the time of seed sowing. Early planting allows the seedlings to become strong before winter.

I have briefly touched upon the plan of later sowings and wintering in frames, but this is only in extreme or isolated cases. In most gardens, given well-prepared soil, the carnation will winter well if well rooted before we have severe weather. After a severe frost it will be well to tread round the seedlings, as they suffer if at all loose at the collar: hence my remark earlier to make the seedlings firm at planting.

When flowers are forming freely, carnations well repay copious supplies of moisture, if the soil is light, late in the day. Bud thinning is not frequently practised, but it has a wonderful influence on the health of the plants, and with varieties inclined to make a pendulous growth, it assists in strengthening them. Early staking and tying are important to keep the blossoms clean, and when the plants are grown in rows it is an easy matter to support them with twine and a few stakes at intervals.

Soils and Diseases.

Any good garden soil will grow seedling carnations, as these are so much more robust than layered plants, but there must be ample food provided by good manure and deep digging.

As regards enemies, I have referred to wireworm, and would advise fresh lime, freely used in the winter, as this also keeps slugs and snails at bay especially. Dress the surface soil with soot previous to planting. Leather-coated grubs I found troublesome in our light soil, but these are proof against the remedies advised, and only hand-picking was any good; they are most active at dusk, and can be caught readily with the aid of a light. G. Wythes.

FANCY CARNATIONS.

All carnations are beautiful, be they flakes, bizarres, picotees, selfs, or fancies, or of border or tree type. The question is often asked, "What is a fancy carnation?" The answer is, it is an embodiment of all the other classes. During the process of improvement by cross-fertilization from time to time factors have been dropped out and others created, as the case may be, and produced this striking type of flower. The old style of florist disdainfully spoke of them as mongrels. It is to be regretted that there are to-day those whose tastes are so vitiated that they are disposed to disregard, and speak with a strange indifference of, any particular section of the carnation family which they do not, or cannot, grow themselves.

During the last two decades (thanks to the splendid efforts of the late Mr. Martin R. Smith) the advance made in the production of fancies has been little short of marvellous. Twenty years ago it was difficult to find a dozen dissimilar varieties, but today they can be obtained in an almost endless range of variety, with a diversity of colour markings of a most fascinating kind, disposed on white, yellow, lavender, and other coloured grounds. The flowers are of large size, indeed, as a class; the fancies produce larger flowers than any other section of the carnation, with the exception of the Malmaison. In spite of the cool reception given them by the old florists, fancies now hold high rank in the large carnation exhibitions held in this country. Their advance has been irresistible, so much so that now they largely control the fixing of the dates for the National Carnation and Picotee Societies' shows. This control has been gained at the expense of the flakes and bizarres, which are now rarely shown at their best, as they usually bloom about a fortnight earlier than the fancies.

Yes, the fancy has fairly ousted many of its old relations. This I regard as unfortunate, but it is not to be wondered at, as not only are the fancy flowers large, bold, solid, and graceful, but the brilliancy and wonderful distribution of their colour markings give them a loveliness that is peculiarly their own, and beautiful to look upon.

All who have a taste for gardening should find room for a few fancies. The cultural treatment is similar to that of all carnations grown in the open border, except that the tree varieties should be propagated by cuttings instead of layering, as is usual with plants grown in the border. The fancies have already found their way into hundreds of gardens, but there are still many lovers of flowers who think that the plant which produces this type of flower is of a delicate constitution. The truth is that, as a class, fancies are extremely vigorous, with strong stems and healthy foliage, and the flowers, with a few exceptions, will withstand rough or hot weather much better than any other type of carnation. They thrive in almost any soil that is well cultivated.

An open position where there is plenty of sunshine is best for them. They should not be planted near such greedy consumers of plant food as sweet peas and pyrethrums, as not only would they be robbed of their fair share of food in the soil, but would be overshadowed and prevented from obtaining that free circulation of air which is so essential to healthy growth. Too often carnations are placed in a nice "cosy" position, and starved or coddled to death by inexperience. The application of strong manures is also to be deprecated, as it lays the foundation of many disorders. When the plants are well established, soot, which is said to be a complete manure, should be freely sprinkled on the border and hoed in. The judicious application of soot improves the colour both of foliage and flower. Should the weather be very hot at the time the flowers appear, a light shading from the noon-day sun with art muslin would be beneficial.

It is doubtless true that plants of any kind grown in and near London do not thrive so well as in country districts, where the air is purer. How far this applies to the flowers of carnations in the winter months we are all too painfully aware. In the summer, however, things are very different, and flowers from the district of London are often the best. At the National Carnation and Picotee Society's Show in July, 1912, the Martin Smith Memorial Cup and the cup for the second division were both won with flowers from plants grown in North London by Mr. Robert Morton. Anyone who saw the fancies in these exhibits would require no further proof that they thrive in London air.

For the information of those who are unacquainted with fancies, I mention a few varieties known to me as strong and vigorous in habit of growth. Yellow grounds: Father O'Flynn, Jno. Ridd, Liberté, Linkman, Lord Steyne, Pasquin, Renown, Queen Eleanor, and Ronny Buchanan. White grounds: Delicia and The Bride. Lavender ground: Persephone.

From now to the end of March is a good time for planting. All the above-mentioned varieties produce handsome flowers, and may be obtained in small pots at little expense, and, with careful propagation, it will not be necessary to buy fresh plants for years. These, like all other plants, demand attention if good results are to follow. My advice to the beginner is (having obtained the stock) plant firmly, and do not water them in. Avoid at any time being too venturesome in the application of water. Grown in pots they will require more attention and give better results, but, though you may have the finest soil in the kingdom, disaster will be sure to follow the indiscreet use of the water can, especially if the plants are in pots. Believe me, seven-eighths of successful pot culture of the carnation lies in knowing when the plants really require watering. The whole twelve varieties mentioned can be purchased, in pairs, for about twenty shillings. I mention this because, in a recent issue of a gardening paper, a correspondent suggested that it would cost £5 to buy sufficient plants to put up six carnation blooms in a local show. My last word is, purchase the stock from a grower who has a reputation to lose, and is, therefore, careful to see that the plants he supplies are strong and healthy.

Jas. Fairlie.

PLANTING OUT CARNATIONS IN SPRING.

In the cultivation of border carnations both autumn and spring planting find favour with different cultivators; but the time at which they are planted out depends largely upon the climatic conditions, and the nature of the soil. I am of opinion that the best results are obtained by planting in spring, the plants having been potted into 60's during the autumn, and placed in cold frames for the winter. Under such conditions it is an easy matter to regulate the treatment, and to keep the plants moderately dry at the roots, which is essential for the successful management of carnations during the dull season.

In a number of instances the question of frame accommodation is undoubtedly a consideration, but if an effort is made to provide space for the plants under glass during the winter, the cultivator will be amply repaid by the superior results obtained during the flowering season. Of course, where carnations can be successfully wintered out of doors in their flowering quarters no exception can be taken to the system, but it is only in favourable localities that this method of cultivation gives really good results. Where the ground is heavy and retentive of moisture it is not advisable to attempt autumn planting, as a considerable proportion of the plants would probably become diseased.

The preparation of the soil calls for careful consideration. A well-cultivated medium loam is the best for carnations, although almost any garden soil can be made suitable. The site that is chosen should be prepared early in the year by bastard trenching but there is no perceptible gain from adding a large quantity of organic manure to ground intended for carnations unless it is very impoverished and lacking in humus. A good plan is to choose a site that was well manured the previous year, but if it is considered desirable to add more nourishment to the soil apply a good dressing of bonemeal, and mix this thoroughly with the top spit. Heavy retentive soil is greatly benefited by the addition of some coarse sand and flaky leaf-soil, while some good wood ashes may also be incorporated with advantage.

The end of March is the best time for transferring the plants to their flowering quarters, and a mild, genial day, when the ground is in good working condition, should be chosen. In the meantime, give the plants as much air as possible on all favourable occasions. When carnations are grown for cutting purposes it is advisable to plant them in rows across a suitable part of the garden, and to leave an alley two feet wide after every four rows, to allow space to attend to the plants and cut the blooms. The plants should be a foot or fifteen inches apart each way, the latter distance for preference. See that the soil is fairly moist before they are turned out of the pots, and take care not to damage the roots, but retain the ball of soil intact when planting out. Press the soil firmly around the roots, and finish off the work in a neat and tidy manner.

When carnations are planted for garden display, the beds or groups may take a variety of forms, according to the grower's taste. Whole borders can be planted with them where space permits, and probably this method is the most satisfactory of all, as brilliant stretches of colour are then obtainable. Scroll-shaped beds look remarkably well planted with carnations when bright colours are chosen, but when these are in close association it is important to choose colours that will harmonise, or to keep to one variety. Where space is limited groups consisting of not less than seven plants can be placed in the herbaceous borders with good effect, and by this means quite a large variety can be grown.

When the plants are established in their flowering quarters it is an advantage to run the hoe through them occasionally to keep down weeds, and check evaporation in dry weather. As growth advances a light dressing of a reliable carnation fertiliser will be beneficial, and should be worked into the soil with the hoe.

CARNATION BOB ACRES.

A very handsome border variety, wholly of a rich scarlet colouring, shown successfully by Mr. James Douglas, Great Bookham.

Varieties of border carnations are very numerous, and many of them have beautifully-formed flowers, while they cover a wide range of colours. Selfs are probably the most effective from a decorative point of view, in a cut state, and are certainly more telling when seen in a mass, but fancies, flakes, and bizarres also have their attractions.

Mrs. H. J. Cutbush is a free-flowering scarlet, and a vigorous grower, being one of the best as a cut flower variety. Cardinal and Volunteer are both attractive scarlets. Leander is a lovely salmon-pink, and Bridegroom is a large pink, while Ivo Sieright is pink flaked with heliotrope. Lady Hermoine is a delightful rosy-salmon, and a very popular variety, but is rather weak in the stem. Agnes Sorrell is a rich deep crimson, and Old Clove is still popular, largely on account of its delicious perfume. Snowflake, Mrs. E. Martin Smith, and Mrs. Henwood are beautiful white varieties, while Daffodil is a handsome yellow of good form and substance. Mrs. Reynolds Hole is an old favourite, with rich terra-cotta blooms, and Tresilian is a handsome and vigorous variety with deep salmon-pink flowers.

J. Gardner.

Batsford Park Gardens.

THE IDEAL BORDER CARNATION.

There is probably a considerable divergence of opinion as to what constitutes the ideal of any flower, so that I, of necessity, lay myself open here to a considerable amount of criticism, especially as I do not pretend to be a florist in the rigid acceptance of the term. However, I can but outline what I consider an ideal border carnation.

The flower should be symmetrical, and nearly approaching in outline a perfect circle. The petals should neatly overlap, and there should be such fullness in the centre as gives depth and substance, without the suggestion of coarseness or crowding. Nor should the stigma be visible in the perfect flower.

The perfect flower should, of course, be fresh. The outline of its petals should be smooth, and not serrated, and the flower should possess such freshness as gives lustre to the colour. The petals should retain an expansive position without falling back or being inclined to incurve, as if there were not strength for expansion. Nor should the petals lack substance, and their strength or substance should be able to withstand the test of touch as well as of sight. The quality of freshness is one which should be insisted on.

But I think particular emphasis should be laid on the attribute of fragrance. We know that, unfortunately, many carnations of delicious colour are absolutely devoid of fragrance, yet it cannot be denied that this is one of the most charming and compelling attributes. If, as would seem to be the case, we must, in the acquisition of more refined colours, sacrifice fragrance, the verdict of all flower lovers will be that the sacrifice is far too great.

In our conception of the ideal carnation we would insist on clarity of colour. Too many are the varieties where the difficulty of defining the colour is great because there is not sufficient clearness—the colour, in the catalogued term, is "suffused," but the truthfully expressive term would often be "washy." With clarity of colour is closely allied intensity, which is the true mark of a good flower.

In the matter of size we lay ourselves open to criticism, for we must confess to favour a large flower. Nor is there anything unreasonable in this. If we have in the flower the qualities named in this article it is but human that we should want those qualities in plenty, and that plenty is provided in a large flower. A large flower need not be coarse, need not be ragged, need not overcrowd its petals, need not be lacking in symmetry, while a small flower may quite conceivably have all these bad traits. Therefore, provided the form, fullness freshness, fragrance, and colour of the flower are present let us have the bloom large—larger.

Proof against sunburn is another quality which should be present in the perfect flower. It is difficult, perhaps impossible, to wholly achieve this in some colours, but that is our ideal, for if it be a defect, and I think there can be no question in that, our efforts should be directed towards its removal. When grown in the greenhouse shading can so easily be accomplished that the defect is scarcely noticeable, but to be forced to shade border flowers is to spoil the decorative effect, and in itself is sufficient to exclude such varieties from the garden.

Furthermore, the flower must be true to type and to class. Any suspicion of breaking away from the variety, the class, or the type suggests fickleness which is a quality not to be tolerated in a flower, as in a human being.

A further quality essential to the ideal flower is that it keeps its freshness, its colour, and its beauty for a considerable time, whether on the plant or in a cut state, and that the flower will well withstand adverse conditions of weather. Obviously a flower which lasts for a considerable time is worth two whose beauty is very transient.

If the calyx of a carnation splits the beauty of the flower is lessened, for even if we resort to the expedient of wire or rubber rings it cannot but be recognised that there is a defect, and that we are doing for the plant what it should be capable of doing for itself. We can only suggest that the defect be eliminated, or, at any rate, lessened, by a rigid and hard-hearted process of selection, and that it be prevented culturally by an endeavour to grow the plants steadily without a check, so that the tissues of the calyx do not lose their elasticity when responding to the pressure due to the development of the flower.

The flower must stand erect on a long, strong, wiry stem furnished with several lateral buds, and, while being duly supported by a suitable stake, it should be sufficiently rigid to ensure an erect habit when set in a vase as a cut flower. The full length of stem for use when cutting can only be obtained when but one flower is allowed on a stem, or when the crown and the lateral buds open simultaneously, or nearly so. This is more noticeable with some varieties than with others, and if the flowers are grown for cut purposes it would be well to select plants for the purpose which exhibit this quality, while for the decoration of the border and the extension of the period over which the beauty of the plant lasts a succession of flowers should be aimed at.

If a plant is to be beautiful, its beauty must be widespread. It must so envelop the plants as to betray itself in all parts. An ideal carnation must have ideal attributes in connection with the habit and constitution of the plant. The foliage must be plenteous and healthy, and should preferably be sufficiently strong to dispel the suggestion of wilting, and yet not so erectly set as to be stiff and coarse. A glaucous green, well clouded with "bloom," makes, in my opinion, more for beauty than does the colour which tends more closely to a pure green. It is preferable also, both for the artistic appearance of the plants and for greater convenience of layering, that the grass be low and short-jointed, and that while the growths individually are fairly strong they are also fairly numerous.

The constitution of the plant must be judged by the class to which the carnation belongs, by the variety, and by the cultural treatment. The aim in carnation culture should be to put vigour into the plants, without which they cannot impart vigour and beauty to the flower. The raising of new varieties—or should we not rather say the express methods employed for increasing the stock of a new variety?—is often done at the expense of vigour. It is hard, indeed, to turn our back on a new variety, with some new and pleasing shade of colour, but the true interests of the carnation are best served by insistence on a high standard of inherent vigour being maintained.

With the increase of new varieties and a decrease of vigour comes a greater tendency to disease and a lesser power of withstanding the attacks of pests. Despite all the researches chemically, and their promotion commercially, we are still grievously tormented by pests and diseases, so that much of the time which could so profitably be devoted to culture has perforce to be expended in combating these evils. Now if a higher standard of vigour were insisted on, if ideals in the plant were as vigorously pursued as are ideals in the flower, we should see the beginning of an era when the power of the pest would be considerably diminished.

To sum up: Our ideal border carnation, then, should have beauty and symmetry of form, fullness and freshness of flower, deliciousness of fragrance, clarity, intensity, and delicacy of colour, large size, devoid of coarseness, proof against sunburn, trueness to type and to variety, lasting property alike on the plant and in a cut state, non-splitting of calyx, length and strength of stem, simultaneous flowering of crown and lateral buds, close, short, and compact habit of grass, and such vigour of constitution as will, to a large extent, defy the ravages of pests, and leave the plants practically unscathed by bad weather. If we have these qualities in a border carnation surely we can want no more.

Let us then do our very best to forward the realisation of these ideals, and this, we venture to think, can best be done by studying the plant, carefully attending to its every want, and using all our powers of selection and re-selection. Let us endeavour to choose only those varieties which come most closely to our ideal, and lastly, let us do our best to diffuse cultural knowledge and encourage care in selection among all lovers of the "divine flower."

W. F. Rowles.

Falkland Palace Gardens.

ARALIA VEITCHI.

This, and its still more slender variety gracillima, form very pleasing table plants, as owing to their delicate nature they obstruct but very little of the view across a table. These aralias are not easy to strike, but they may readily be grafted on stocks of Aralia reticulata, a species with narrow leaves. This is readily propagated by means of cuttings. When employed as stocks they should be established in small pots.

Given a supply of suitable stocks a considerable number of plants may be obtained from one of Veitchi, which may perhaps have grown too tall, and become bare at the base. Not only does the top of the plant form a good scion, but each bud may be so employed. The bud should have its attendant leaf left on. Side grafting is the best for the purpose, and, of course, the point of union should be as near the ground as possible. A sharp knife is very necessary. If the cut portions fit well together, and are tied securely in position, a union will soon take place, provided they are placed in a close propagating case in the stove, and are kept shaded from the sun. When the young plants are sufficiently advanced to shift into larger pots they may often be buried deeper than before, so that the point of union will be wholly or partially covered. S. W.

EXHIBITING BORDER CARNATIONS.

The method of exhibiting the border carnations to-day presents a very striking contrast to that of a century ago, when growers conveyed their blooms to the exhibitions in their coat pockets. Each individual bloom was encased in a tin receptacle resembling a mushroom in appearance. Some of those used by my grandfather are still in my possession, and are, probably, the only relics left of this curious old custom. About a dozen blooms were then a maximum number for a grower to exhibit at any one show, whereas it is now a common occurrence for an exhibitor to stage from five hundred to a thousand blooms at one exhibition.

From this time until 1893 the only method of staging was in the familiar green boxes, with paper collars. In the year mentioned the Midland Carnation Society led the way by adding classes for blooms shown on long stems in vases. These classes proving a great success they were soon copied by other societies, and it became necessary to differentiate the two styles. They are now technically known as "dressed" and "undressed" classes. Each style has its own distinct merits. The dressed classes demand that fine petal, perfection of form, and quality, without which the present excellence of the flower could not have been obtained. In the undressed classes the decorative effect is the first consideration, and demands bold, large flowers of striking colours and tasteful arrangement.

To new exhibitors the following advice on methods of staging and exhibiting may be useful. The best time to cut the blooms is early in the morning, while the petals are fresh and stiff, as if they are cut during the heat of the day, or in the evening, many of them will close, or "wink oop," as the Northern growers say, on the journey to the show. Have some vases full of clean water to place the stems in as soon as cut, and be sure to place them in a cool, airy place, though not in a draught. The flowers for the vase classes may be taken to the show in shallow boxes; they may be laid lengthwise, side by side, but it is well to make a roll of paper to rest the pods on to prevent the petals rubbing on the bottom of the box. At most exhibitions wires, "as a mere support," which must come beyond the base of the calyx," are allowed, and these are of great advantage, both for packing and staging, as you can bend the stem to any angle you like with their aid.

Before staging it is well to look over each flower with your tweezers, even in the "undressed" classes, gently guiding the petals into place, and then place the blooms in the vase, packing them in firmly with a little green moss, and then bending the stems round to the best angle to face the judges.

This procedure in exhibiting in the classes for blooms on cards is widely different. If you are showing twelve blooms cut about fifteen with as much variety as possible, and, having filled your tubes with water, take the largest bloom in your left hand, and commence the important operation of dressing. With a pair of steel tweezers turn down the points of the calyx in each of its divisions, thereby gaining a larger size. Then, having loosened each petal from its neighbour with a pair of ivory tweezers, put on the card, and commence to build the flower up, first by gently drawing out the guard petals to the edge of the card, and following up with the next row laid over them, in the manner of the slates on a roof till you have built the flower up, as near to the shape of half a ball as you can get it. The top petals should be drawn up to the centre to form a crown for the flower.

Each exhibitor seems to have his own particular method of putting the finishing touches to a flower, some dressing it with a flat crown, and others with the petals standing up in the centre. My own practice is to note the natural habit of the variety, and to dress it accordingly.

A method to be avoided is one that is sometimes adopted. It consists in twisting the petals across the centre of the flower to fill up a hole, making a kind of knot in the centre, and giving it an unnatural appearance.

A few points of a general character to be remembered are: Always have your boxes or vases ready and properly cleaned beforehand. Good flowers exhibited in a slovenly fashion are like a splendid jewel in a bad setting. It is not fair to the jewel. A point also to be emphasised is to avoid extremes of size. It is better to leave a very large flower out of your stand than to have its size dwarf all the rest of your twelve, and make them look smaller than they are. Lastly, be a good loser; we cannot all win, and if beaten to-day, by noting your own weak points you may turn the tables at the next attempt.

King's Norton. A. R. Brown.

CARNATION MRS. GEO. MARSHALL.

One of the finest of self-coloured border carnations; the colour is rich glowing crimson. The flowers shown were successfully exhibited last year by Mr. J. H. Lakeman, Thornton Heath.

HELIANTHUS TOMENTOSUS.

Here we have a border plant with greater attractions than most of its sister sunflowers. It was first introduced to this country as Helianthus mollis, and an Award of Merit was given to it under that name by the R.H.S. The true H. mollis, however, has more flowers, and these are not so large, while the plant is less woolly. In H. tomentosus we have a border flower which grows from five to six feet high, the latter height being only attained in a good border of rich soil. The stems are quite woolly, and the leaves are of a silvery grey. The blooms are of a fine shade of orange. The tomentose sunflower is quite hardy, and is propagated by division or seeds. Planting for autumn bloom may be performed until March.—S. Arnott.

WATERSIDE PLANTING.

The presence of water in some shape or form greatly increases the attractions of any garden, and its entire absence is a matter of regret. Many are the gardens, admirable in most respects, in which the only thing lacking is water. Whether this is present in the form of a lake, pool, river, or murmuring streamlet, it is always welcome in any garden, but it is on its surroundings that its appeal to the eye chiefly depends, and considerable thought should be bestowed upon their artistic grouping. If they are pleasingly disposed they increase the beauty of the water, and produce a picture of entrancing loveliness, but if the arrangement has not been carefully considered, with a view to effect, the probability is that the landscape will lack much of its possible charm. It will be generally admitted that some description of planting is very desirable on the shores of a lake, since an open sheet of water, with its sides destitute of all manner of plant growth, misses one of the chief beauties of still water, that of reflection of adjacent objects, and only the floating clouds can be mirrored on its still surface.

CARNATION DROITWICH.

A new white-ground fancy border carnation, the markings of a rosy-red hue. Raised by Rev C. A. Gottwaltz, and distributed by Messrs. Arthur R. Brown, Lim., Wychall Nurseries, King's Norton, Birmingham.

It being admitted that the margins of lakes should be diversified by various plants, the next question to be thought of is the subjects to be used, and the manner of the planting. This should not be carried to excess, as nothing should be more carefully avoided than to so hide the sheet of water, that, from some little distance, it cannot be seen. Before planting is begun care should be taken to discover from what situations the most charming views of the water are to be seen, and on these spots no shrubs or plants should be permitted to interfere with the view. Originality of planting should be studied, since nothing so detracts from the beauty of a lake as the appearance of monotonous uniformity in its surroundings. This, however, is too generally noticeable, the same plant being often seen arranged in groups at equal distances on the shore, this creating a sense of dull sameness. Plants of distinct growth should be set by the waterside, for nowhere is habit so noticeable as by the margin of a lake, where they are massed in small isolated groups, so that their habit of growth may be adequately displayed.

Contrasts of form often give a very attractive picture, as when a lofty group of some lovely bamboo, such as Arundinaria Falconeri or Phyllostachys henonis holds aloft its slender, graceful canes twenty feet or more in height, set with gently waving leaves, close by a great colony of the majestic Gunnera manicata, whose huge leaves, carried on tall stems, spread ten feet across, and show wonderful diversity of growth. The plants available for growing by the waterside are many and varied, and different conditions of soil are at hand —dryness on the ascending banks, moisture on the lower levels, where it may be reached by the descending roots, and at the water level soil that is constantly damp, where bog plants may be grown.

Of the nobler foliage plants there is nothing to excel the gunneras, G. manicata, a native of Brazil, and G. scabra, from Chili. Both of these are fine plants, but the foliage of the former is larger. They are not quite hardy, being often severely injured by the late spring frosts even in Devon and Cornwall, but they will grow as far north as Worcestershire. The yuccas are very valuable, both for their handsome foliage and their white flower spires. They should be grown in colonies of one species. They are attractive even when not in flower, and when in full bloom Yucca gloriosa and Y. recurva are extremely handsome, while Y. filamentosa generally flowers annually. The great saxifrage, S. peltata, is a native of California, but as it is at rest during the winter it is rarely harmed by the frost. A tall flower spike, about three feet in height, is thrown up in April, and bears a large head of pale pink flowers. The deeply-cut leaves succeed the bloom spike, and are over a foot in diameter. It is very partial to moisture, and will grow in the middle of a small stream.

Arundo donax, with its lofty shafts, from which the blue-green pennoned leaves flutter, is extremely effective when grown in an isolated position. It sometimes attains a height of twenty feet. The beautiful variegated form is more tender, and sometimes dies even in the south-west The phormiums, or New Zealand flaxes, are very handsome plants, with their long, erect, sword-shaped leaves, often eight feet in length, and are hardy, even in Scotland. Though there are many varieties, P. tenax and its variegated forms are as good as any. All spiræas delight in a moist soil, and of the herbaceous section, S. armens, S. astilboides, and S. palmata are among the best, while of the shrubby class, S. ariæfolia, S. Lindleyana, and S. arguta are hard to beat.

Many of the primulas appreciate moist soil, and flourish to perfection where they are grown in damp spots. In a certain

Cornish garden the rose-coloured form of P. japonica grows for a distance of over a hundred yards by the side of a lake beneath lime trees, and when in full bloom the wide belt of flowers presents a lovely picture, their bright colouring being reflected on the still sheet of the lake. Many of them are growing covered by an inch or two of water, and self-sown seedlings spring up in countless numbers. P. sikkimensis, with its pale yellow, drooping sweetly-scented flowers, is also equally happy by the waterside, as is P. rosea, which succeeds best at the water level, and produces a bright display of vivid colour in the spring.

Some lilies, such as L. pardalinum, L. superbum, and L. canadense thrive in moist, peaty soil by the waterside, and the North American Cardinal Flower (Lobelia cardinalis) delights in damp soil. Day lilies will also do well, two of the most effective being the common Hemerocallis flava, yellow, and H. aurantiaca major, with large orange-yellow blossoms. A striking plant that will succeed in moderately moist soil is Eryngium pandanifolium. It has long, narrow, grey-green, spined leaves, and very lofty flower heads, often ten feet in height, which are set with numerous greenish, rounded bloom heads.

Rodgersia podophylla is an extremely handsome and noble foliage plant, a native of Japan. It has large leaves, deeply divided, which are carried on tall stems, and turn to a rich bronzy tint in the early autumn. It throws up a tall flower spike of white blossoms, which is borne well above the foliage in June, and is very pretty.

A SUCCESSFUL EXAMPLE OF WATERSIDE PLANTING.

A beautiful scene in the Japanese garden at Watermouth Castle, Devon.

The newly-introduced R. pinnata is also an attractive plant, and appreciates a damp spot. The polygonums are, as a rule, unfitted for the borders and beds in the garden as they spread so rapidly, but by the lakeside they do no harm, and, if planted as isolated specimens, when the shoots bend outwards elegantly they are strikingly effective. The two best suited for planting by the lake are P. cuspidatum and P. sachalinense. They are both large plants many feet in height. When bearing its graceful white flower panicles the first-named is very pretty, while the large pale green leaves of the latter are of pleasing appearance. The noble Acanthus latifolius, the leaves of which suggested the Corinthian capital, is an exceptionally fine plant, and will succeed well in the drier spots, as will one of the finest of our foliage plants, the Globe Artichoke, Cynara Scolymus, which, with its arching, grey, deeply-cut foliage, is very ornamental, though it is rarely seen out of the kitchen garden.

Other subjects that will succeed by the waterside are the Monkshood (Aconitum napellus), Michaelmas daisies, Globe Flowers (Trollius), the deep rose variety of the loosestrife, and some of the stronger campanulas, such as C. grandis and C. latifolia. The arum lily is a splendid water plant, and if grown in a foot of water the roots will be unharmed, even if the foliage is killed. In a certain Cornish lake it is grown in countless numbers, and early in June a thousand or more blooms might be cut without materially diminishing the display.

Some of the terrestial orchids are very valuable for planting in damp, peaty ground by the waterside. They require to be kept moist during the entire year. The Mocassin Flower, Cypripedium spectabile, is one of the best and loveliest. The petals are white, and the large pouch is of a soft rich rose colour. It is a native of North America, and perfectly hardy. Another handsome species is C. pubescens, which bears yellow and brown flowers. It blooms very freely when well established.

Wyndham Fitzherbert.

RUSCUS RACEMOSUS.

This ruscus, also known as the Alexandrian Laurel, a title derived from its supposed identity with the victor's laurel of Mount Olympus, is one of the most beautiful of foliage plants. In growth and habit it is not unlike a dwarf bamboo, producing slender, bamboo-like shoots about four feet in length, set with glossy green pointed leaves (or cladodes) about two inches in length. In the spring its small greenish-white blossoms make their appearance in little clusters at the points of the shoots, but it rarely fruits in this country. It is, perhaps, the most valuable of all foliage plants for indoor decoration, its arching growths being very graceful, and the shining leaves retaining their freshness when cut and placed in water for fully two months.

As a native of Portugal, from which country it was introduced in 1739, it cannot be considered absolutely hardy everywhere throughout this country, but there are spots in most gardens where it would be found to succeed. Though not particular as to soil, it is partial to a chalk formation, and does best in partial shade; indeed, it might be well used for undergrowth where sufficiently plentiful, in place of the common native Butchers' Broom (Ruscus aculeatus), a far less ornamental species. The correct name for Ruscus racemosus is now held to be Danæ racemosus.

Wyndham Fitzherbert.

SUPPLIES OF GREEN VEGETABLES.—II.

Cabbage.

Good cabbages find favour in all gardens, whether large or small, but as soon as other choice vegetables come in, they are but very little in request, therefore it is not advisable to grow more of these than is really necessary to supply the household during the early summer. From April to June they are most appreciated, but when peas become plentiful there is but little demand for them. It is the earliest cabbages that are most in demand, therefore the aim should be to have them as early as possible. If a sowing is made in August of some such variety as Ellam's Early, Mein's No. 1, Harbinger, and Flower of Spring in warm, sheltered situations, good hearts may be cut in April. There is no need to grow a long list of varieties, as they take up too much room.

Where there is likely to be a demand in the autumn for cabbages, a pinch of colewort seed may be sown in July. Plants raised from this sowing, if put out about a foot apart, will soon turn in.

To produce nice, crisp, early spring cabbage, the ground must be in good heart, and if of a warm, dry nature, the growth will be more rapid than in that which is cold and unfavourable, therefore those who have this latter class of soil to deal with should select one of the warmest and driest portions of the garden on which to plant the early cabbages. The seeds should be sown from the end of July to the middle of August, according to the district; if sown too soon the plants are apt to run to seed after a severe winter. When the plants have made three or four rough leaves, they should be pricked out to keep them dwarf. At that time of the year, the soil being warm, growth is very rapid, so a close watch must be kept on the plants to see they do not become drawn. Choose a showery time, if possible, to put them into their permanent quarters. In most gardens the plot from which the spring onions have been lifted will be a suitable one, though in some gardens which have naturally a cold soil a warmer spot should be chosen. It is not necessary to plant these small-growing kinds far apart, as they make but few outside leaves; about eighteen inches will be ample, the object being to get the crop off as soon as possible to make room for others, and, as the cabbages are usually cut before they are fully grown, this can readily be accomplished. To induce the cabbages to grow more rapidly in early spring, give a sprinkling of finely-powdered nitrate of soda between the rows in March. The rain will soon wash this down to the roots, and its effect will be seen in a few days if the weather should be fine and warm.

Cauliflowers.

The delicate heads of this vegetable are much appreciated in May and June, but after that they are not usually called for until the autumn approaches. To obtain nice white heads of cauliflower early in the season much care is needed, for the seed must be sown under glass in January or early in February, and the plants brought forward on a slight hotbed. The earliest batch must be grown under glass until ready for use, while those to succeed them should be potted up when small, and kept growing in cold frames until it is safe to transfer them to the open quarters in April.

There are now several very early kinds on the market, such as First Crop, Early Forcing, Emperor, and Pearl.

Cauliflowers, when grown under glass, are very liable to damp in a young state, therefore every precaution should be taken to guard against this disaster. As soon as the seedlings are large enough to handle they should be pricked off. Avoid too much moisture, both at the roots and in the atmosphere, until the plants have attained a good size, then they must not be allowed to become dry at the roots, or in all probability they will "bolt." The plants that were potted up, after being duly hardened off, should be put out in a warm, sheltered place about the middle of April. Choose showery weather for the operation, if possible, but, should the weather be dry at the time, give a thorough soaking both before and after planting. As there should be good balls of roots and earth, there will be no necessity to shade from the sun.

For an autumn supply there are none better than Autumn Giant and Mammoth; both are good kinds, and will turn in during September and October. To produce good heads at this time of the year is not difficult. The seeds should be sown in the open in March, and the plants put out as soon as they are ready, on a piece of well-prepared ground that has not been occupied with any of the brassica tribe for a couple of years. Should the soil be of a light sandy nature a mulching of thoroughly decayed manure will prevent evaporation, and conserve the moisture that is in the soil. Cauliflowers of this class make large foliage, and, therefore, need much support to enable them to form fine heads of close texture.

Savoys.

These are not much appreciated before December, and from then onward until February or March they are in great demand. Small, compact hearts find most favour in private establishments, not the large, coarse, overgrown kinds that partake of the flavour of ox cabbages. Seeds must not be sown too early; from the middle of April to the first week in June, according to the district and the variety cultivated, will be soon enough. The quality of the land has much to do with the production of first-class Savoys. The soil cannot well be too rich if tender, crisp hearts are to be produced, for the quicker they are grown the more tender they are.

The varieties most appreciated are Perfection, Tom Thumb, Dwarf Green Curled, New Year, and the like. There is also a variety known by the name of Miniature Drumhead, which turns in very quickly, and is very tender. These small varieties may be planted much closer together than the large-growing kinds, from a foot to eighteen inches being ample.

The foregoing kinds are, with those mentioned in the first part of this article, among the most useful of the several brassicas for providing a supply of green vegetables at the seasons when they are most needed, and, by carefully paying attention to the time of sowing and other details, the cultivator should be able at all times to keep up a supply, provided the space at his command is adequate to the demand made. H. C. Prinsep.

Perpetual-flowering Carnations.—The cuttings which were struck in December will now be ready to pot into 4½in. pots. Use a compost of fibrous loam, leaf-soil, and coarse sand. Pot the plants firmly, and when potted place them on a shelf near the glass. Lightly spray them with rain-water once or twice daily, and water with care until the roots have taken possession of the new soil. Pot on cuttings which have been recently struck as soon as they are sufficiently well rooted. Do not expose recently-potted plants to cold draughts or bright sunshine.—E. Harriss.

GREENHOUSE PRIMULAS.

So much has been said and written about greenhouse primulas that anything new concerning them would appear to be out of the question. But every year sees some advance made in the plants and flowers, or in cultivation, or in the uses to which the plants are put. Primulas for greenhouse or conservatory decoration belong to a very few species, but, as in the case of P. sinensis and P. obconica, the varietal range is considerable. Besides these two there are P. floribunda, P. verticillata, P. Kewensis, a hybrid between the two latter; and P. malacoides. P. Forbesi is a charming little species, but P. malacoides has practically put it out of court as a greenhouse plant.

All these can be raised from seeds, and all are available, more or less, for the decoration of homes and glasshouses during the winter season. Of course, P. sinensis still holds the foremost position, but it has a strong rival for public favour in P. obconica. This latter blooms over a longer period, perhaps, and possesses a bolder beauty, but it lacks the refinement of the best varieties of P. sinensis. It is so good, however, and so easily grown by even amateurs with small conveniences, that it deserves all its popularity. As with P. sinensis, so with P. obconica, Messrs. Sutton and Sons, of Reading, have taken up the work of improvement with their accustomed skill and patience, and their colour strains come very true from seeds. Mauve, lilac, lilac-purple, rose, and pink are colours finely represented in the Reading strains, and the plants are strong growers and wonderfully free flowering. It is in the red and white varieties that work still remains to be done. A bright red that is almost scarlet has been produced, and there is a white with a purity beyond all question.

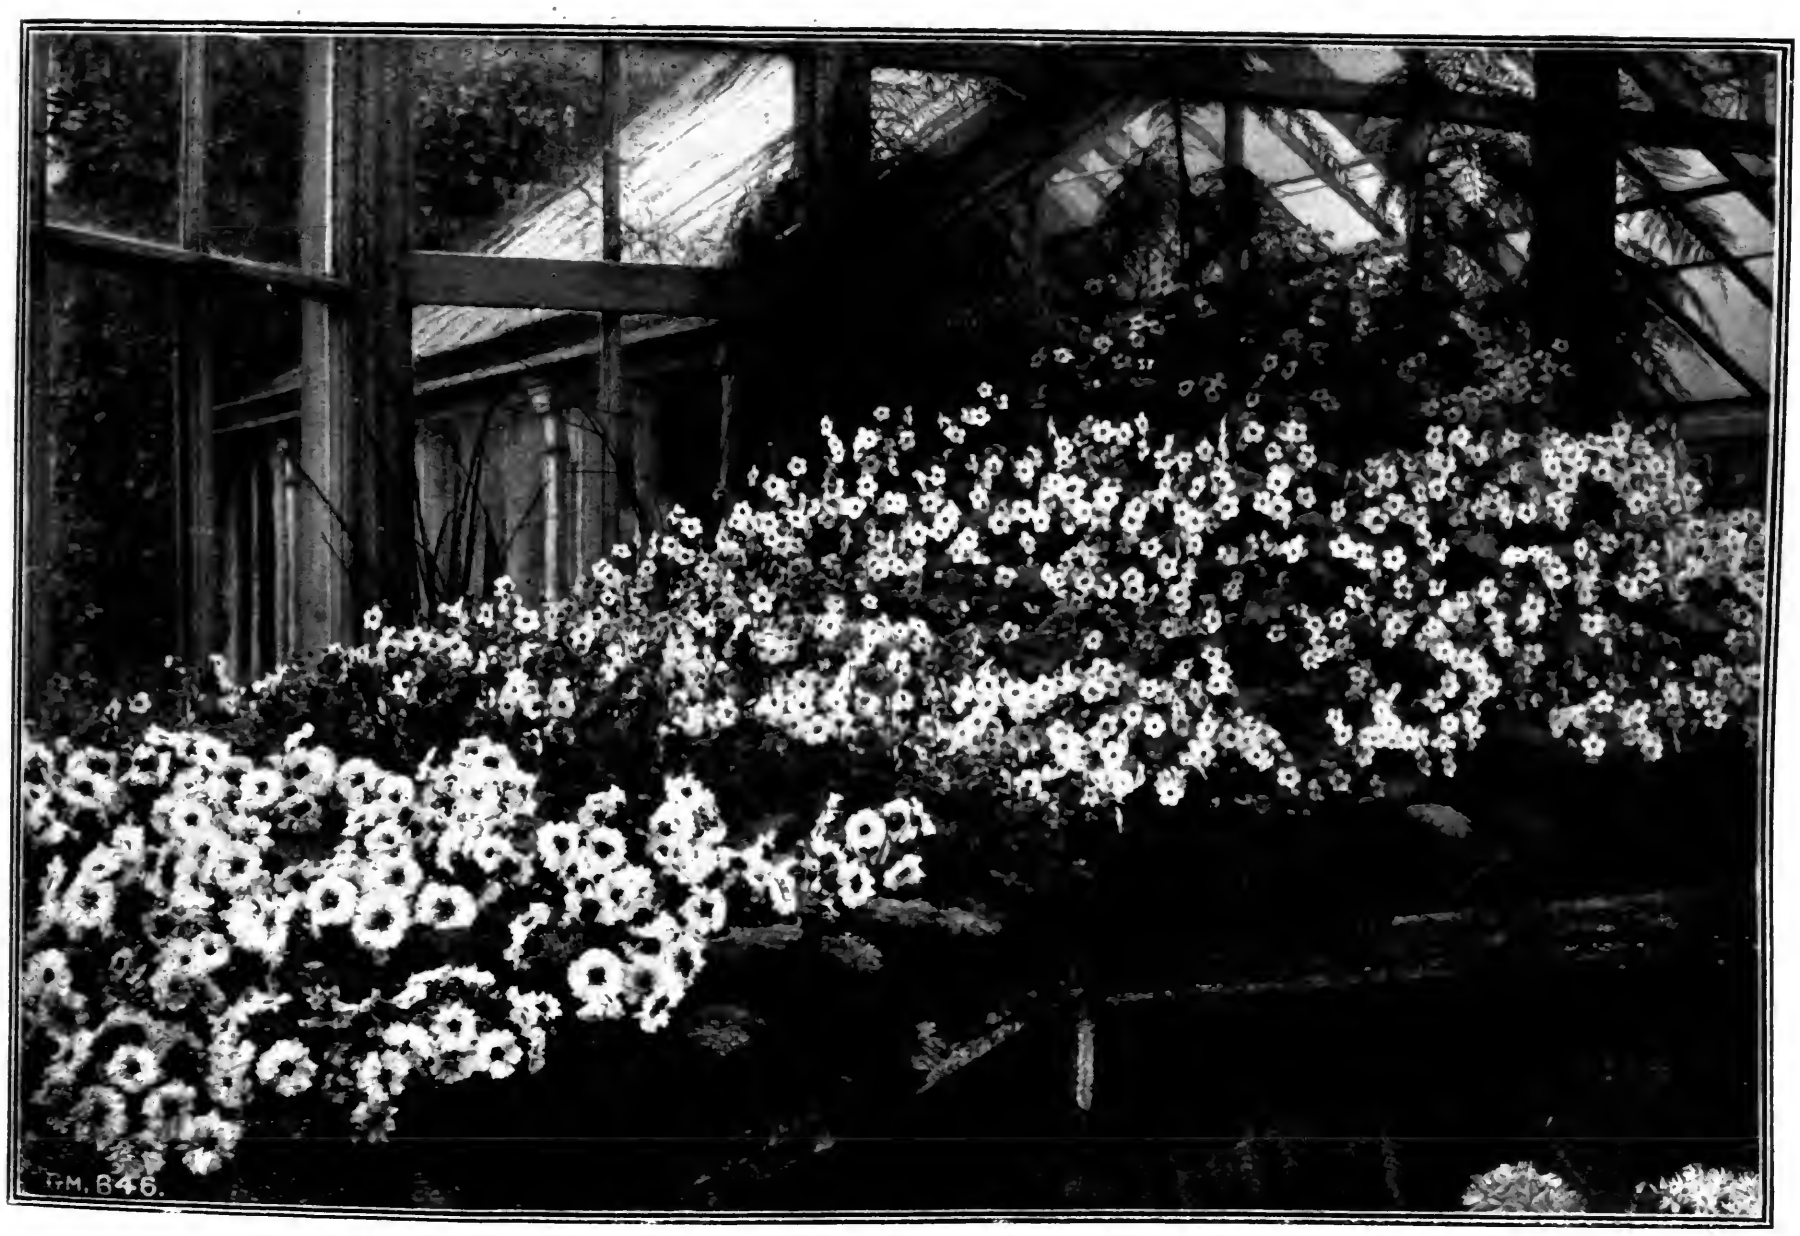
More and more popular do the Star primulas become, and no doubt this popularity will continue just as long as the present ideal of habit and form is maintained. New colours or colour shades are needed, and one can see the process of manufacture at Reading. The original White Star is still the most popular variety of this section, but the blue varieties are obtaining new admirers every year, and the star form of Lord Roberts, with salmon-pink flowers, provides a warm tint very acceptable in winter time. Ruby Star is probably the best form for display under artificial light.

A little idea of the progress made at Reading with Chinese primulas, including, of course, the Star section, may be obtained from the fact that in 1893 Messrs. Sutton and Sons offered twenty varieties; in 1898, thirty varieties; in 1903, forty varieties; in 1908, fifty varieties; and in the present year they offer fifty-five varieties. The offer of fifty-five varieties does not mean merely growing that number of batches of plants for seeds. By no means. Selection and cross-fertilisation is conducted every season and on a large scale, in the hope that some variety may be improved, or superseded, by a better, or that some quite new one may be evolved. In 1893 the number of batches of plants from which seeds were saved separately, either for sale or selection, was 154; in 1898 it was 167; in 1903 it had reached 256; and went on to 431 in 1908, but fell to 340 in 1913. Does the smaller number of seed stocks and selections in 1913 indicate a decline in Chinese primulas? Not at all; the figures simply point to the fact that the application of Mendelian principles has rendered it unnecessary to grow so many of the smaller batches, because the ultimate result of certain crosses is now perfectly well known.

It is hardly necessary to name many varieties of the giant and older races of florists' primulas, but the giants are such a distinct race, so large-flowered, and yet so refined, that the little extra attention they need is amply repaid; there are pink, white, crimson, and salmon shades of this splendid section. Turning to the older type, The Duchess stands out prominently, its rosy-carmine zone round a yellow eye invariably attracting attention and exciting admiration. The Czar, violet-purple; Coral Pink, a happy variety that always suggests springtime to the writer; Crimson King and Reading Scarlet, with brilliant colouring; Snowdrift and Royal White, whites; and Reading Pink, soft pink, fringed flowers, form a good selection, though Reading Blue must be added for those who like its shade.

A new race now being offered is peculiar because the flowers are eyeless. No doubt the few varieties, Snow Queen, Silver King, and Silver Star, will "take on" with those who love novelty. We have become so used to the yellow or orange eye in primulas that its absence suggests that the Messrs. Sutton are not quite playing the game. Hitherto they have added colour, size, floriferousness, fringing, differently coloured foliage, and leaves of fern-like elegance; but now they have taken away something, and we are not yet used to the "naked" look of eyeless primulas. Now, if the Reading firm had gone on with their addition and given us a greatly enlarged yellow or orange eye—in fact, a flower all eye instead of eyeless, there would have been jubilation among primula lovers.

A few combinations of varieties of primulas may prove useful. The following are not mere suggestions, but combinations of proved beauty carried out by Mr. Townsend, gardener to Mr. Leonard Sutton, at Hillside, Reading, with plants of his own growing, not those under Mr. Macdonald's care at the nursery: Dark Blue Star and the golden P. Kewensis, or Ruby Star mixed with P. Kewensis. Giant White Star (Bouquet habit), with a few plants of the mauve P. malacoides. Reading Blue, Royal White, and Pearl, mixed with a few plants of Coral Pink. Reading Blue goes well with The Czar, if only a few of the latter are used among the former; arranged thus the two blue shades are more effective than when separated. Coral Pink and Crimson King intermixed provide a very beautiful combination. Giant Pink and Giant White make an obviously good display together. In the illustration a conservatory group is shown at Hillside, Reading. In the foreground is Coral Pink, followed by the Duchess, Ruby Star, Giant White Star, Pink Star, and Giant White Star again, with Dark Blue Star and P. Kewensis grouped together at the highest point. This scene was so novel in its colouring and arrangement, and so widely different from the methods usually employed in staging primulas in the conservatory, that we have reproduced it.



A CHARMING ARRANGEMENT OF PRIMULAS IN THE CONSERVATORY,
At Hillside, Reading, the residence of Leonard Sutton, Esq.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

THUNIAS.—T. Bensoniæ, T. Marshalliana, and the hybrid S. Veitchiana belong to the section of deciduous orchids, which require a complete rest during the autumn and winter season. They should now be producing their young growths, from the base of the old pseudo-bulbs, and will require fresh material. The old plants should be turned out of the pots, the whole of the decayed soil shaken from the roots, and at the same time all dead and decaying matter should be cut away with a sharp knife. Thunias are usually placed several together in the same pot, the pseudo-bulbs being placed two or three inches apart, taking care that the young growths are kept about an inch below the rim of the pot, so that the potting material may be made moderately firm about the base. It is advisable that each of the old bulbs should have a stick sufficiently strong to secure it until the plants become re-established. The compost should consist of peat, fibrous yellow loam, and sphagnum moss, and a liberal addition of finely-broken crocks or coarse sand to render the soil porous. The pots used should be thoroughly clean, eight to nine inches in diameter, and filled to about one-third of their depth with clean broken crocks, which should be covered with a thin layer of partly-decayed oak leaves. After potting place in a light position in a stove or East Indian house, and as near the roof glass as possible, for unless they have ample light from the commencement of growth, they rarely produce satisfactory results. Thunias should be carefully watered at first, and very little moisture will be necessary until the new roots become established.

PROPAGATION. — To increase the stock thunias may be readily propagated by taking off the back pseudo-bulbs and making them into cuttings about six inches long, which can be inserted as ordinary cuttings, or laid out on sphagnum moss, in a propagating case, or at the warm, moist end of a stove. They will require constant moisture and a strong heat, and as soon as roots are observed, at the base of the new shoots, they should be potted in a mixture of chopped sphagnum peat and sand, every encouragement being then given to produce free growth.

THE PRINCIPAL INSECT PESTS are scale, red-spider, and thrip, but, if the houses are sprayed with some safe insecticide at regular intervals throughout the growing season, these insects may be readily kept in check. Red-spider sometimes attacks the under sides of the leaves where the atmosphere is at all dry. The discreet use of the syringe in favourable weather will considerably help in keeping this pest in check. The plants are exceedingly useful for exhibition during the summer season, and are most effective where used for house decoration. The flowers will last in a room considerably longer even than when removed to a cool greenhouse.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

PRIMULA OBCONICA.—The great improvement which has been effected in this species renders it one of the most useful greenhouse-flowering plants we have. The colour of the flowers covers a much wider range than was the case a few years ago, and the size of the individual flowers, as well as the flower trusses, has been improved. Seeds may now be sown for raising a batch of plants to flower in the autumn. Sow the seeds in shallow pans in a compost of loam, leaf-soil, and sand. The soil must be finely sifted, and the seeds be only lightly covered. Cover the pans with a sheet of glass, and place them on a shelf in a warm house, keeping them shaded until germination takes place. Prick the seedlings out into other pans when large enough to handle, and when fairly established shift them into small 60-sized pots, and keep them growing in a position near the glass in an intermediate temperature. Their final shift should be into 5in. pots.

PRIMULA MALACOIDES.—This is also a very desirable plant for the greenhouse, and deserves more extended cultivation. The method of cultivation is very similar to that of P. obconica. One important point to remember in regard to its culture is that its spikes are very liable to damp off just when they are rising, if water is not carefully applied.

PRIMULA SINENSIS. A batch of Chinese primulas may be raised now, and given similar treatment to the above. With liberal treatment, these will flower during the greater part of late autumn and winter.

LOBELIA TENUIOR.—The colour of this lobelia and its easy culture makes it a very useful plant for the greenhouse during the summer months. Sow the seeds now in pans in a light compost. When the young plants are large enough, prick them out into large 60's, in which size they will flower.

SOUVENIR DE LA MALMAISON CARNATIONS.—Unless it is desirable to hasten these into flower they must be kept as cool as possible. The flower spikes in many cases are rising, and must be securely supported by neat stakes. The plants must now be more liberally supplied with water; stimulants may also be given more frequently, and with increased strength. Fumigate with a nicotine compound to keep the plants free from aphis.—E. Harriss, Lockinge Gardens.

HARDY FRUITS.

NUTS.—The pruning of these may now be pushed forward. In Kent, and other parts where nuts are grown extensively for market, pruning is usually commenced early in the year, and extends over a period of fully three months; but where there are only a few bushes I like to leave them until the tiny pink-coloured female blossoms show. Leave ample catkins to assist fertilisation; cut back all coarse wood and remove all suckers that spring up at the base of the stems; shorten side shoots on the main branches, and endeavour as far as possible to keep the whole of the bush open and clothed with small twiggy, fruitful growths. Commencing with young trees, see that they have a clear stem of 12 to 18 inches above the ground level, and train the heads vase-shaped; when shortening back the leaders, always cut to an eye pointing in an outward direction. Start with three to five shoots, and as these extend allow others at intervals till a good vase-shaped head 7 feet high is formed, when very little further attention will be required except shortening as advised. Old and fruitful bushes will benefit by having a little well-decayed manure pricked into the soil over and about the roots, but, if the bushes grow too gross to be fruitful, do not add manure. Keep the land free from weeds, and dust plenty of lime beneath the bushes after the pruning is completed, at the same time slightly loosening the surface with a fork to prevent the land from cracking in dry weather.

PROTECTING FRUIT BLOSSOMS.—Attend to this before the buds are injured by cutting winds and sharp frosts. The buds are this year more forward than we like to see them, owing to the past mild weather, so that protection may have to be employed earlier than usual. In some parts of the country, and in mild seasons, protection may not be necessary, but it is well to be on the safe side. In the absence of blinds, glass copings, etc., hang two or three thicknesses of fish netting in front of the trees, resting this on poles to prevent injury to the flowers and for convenience. This, with a few small pieces (at intervals) of Portugal laurel stuck behind the branches, will save the blooms during sharp frosts.

VINES.—If these have not yet been pruned they should be taken in hand at once, or the wound will not dry sufficiently to prevent bleeding. Prune the laterals back to a couple of eyes, and secure the leaders. To be reasonably successful with outside vines the position should be good, the border rather elevated, and the roots somewhat confined. The fruiting wood should be as close to the wall as possible, and disbudding and stopping of the laterals will need as much care and attention as in the case of vines grown under glass.

ANY SPRAYING to be done must not be delayed. Dusting all bush fruits, pears and apples, before the flowers get too advanced, with soot and lime, will prove very helpful in cleansing the bark and freeing the crevices of insect pests. — H. Markham, Wrotham Park Gardens.

THE KITCHEN GARDEN.

ASPARAGUS.—When making a new plantation it is a great advantage to prepare the site early in the previous autumn, and subsequently fork over the ground once or twice at least during the winter months to sweeten the land; heavy soils in particular will be materially improved by exposing the top spit as much as possible to the action of the weather. It is most essential the land should work freely ere the time for planting comes round. Should the preparatory operations of trenching, etc., have been unavoidably postponed, the work should be pushed through without delay. Asparagus should be planted in a situation well open to the sun; the land must be well drained, heavily manured and trenched, the rougher portion of the manure being placed in the bottom of the trench. Soil of a very stiff nature should be made suitable by adding road-scrapings, rubbish heap material, wood ashes, and sand to the staple, and be left exposed to the weather till the beginning of April, and, after being scuffled over, should be made level in readiness for planting. Two-year-old seedlings of either the Giant, Connover's Colossal, or Argenteuil should be procured, and placed a distance of 2ft. apart, the roots spread out horizontally and regularly, and then covered with the finer portions of soil in such a manner that the crowns will lay about three inches under the surface. Asparagus roots should be exposed as little as possible to the air, and should be transferred from one situation to another without unnecessary delay. If raised beds are desired, they should not be less than 4ft. wide, with alleys 2ft. wide running between. In preparing such beds—providing the whole quarter has been trenched over—the required distances should be marked out, and the soil from the alleys placed on either side to form the raised beds, which should be about six inches above the alleys when finished. The roots may then be planted as previously advised. The beginning of April is a suitable time to plant, selecting, if possible, a dull, quiet day for the operation. No heads must be cut the first year after planting.

LETTUCE. — Autumn-sown plants which have been hardened off may be planted in a warm and sheltered position. To keep up a succession, it may be necessary to put a portion of the most forward plants in a cold frame; plant in light rich soil, spray on fine days, and close the frames early. If the nights be cold some protecting material should be placed over the lights.

SEEDS.—Sow either in boxes or on a mild hotbed in a frame or pit. Tender and True and Imperial cabbages; Golden Ball and an approved main crop variety of lettuce; Brussels sprouts for early gathering, preferably of the Dwarf Gem class; Magnum Bonum, Snowdon, and Early Mammoth cauliflower, and celery for early lifting. The main sowing of celery seed should be made towards the end of the present month.—W. Messenger, Woolverstone Park Gardens.

NATIONAL SWEET PEA SOCIETY. Great Exhibition at Royal Horticultural Hall, Westminster, July 17, and at Carlisle, Aug. 13 and 14. Join now. Minimum Annual Subscription, 5s. Schedule on application. "Sweet Pea Annual," free to members; 2s., post free, to non-members. CHARLES H. CURTIS, Hon. Sec., Adelaide Road, Brentford, Middlesex.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The society's hall was simply packed with exhibits on Tuesday and Wednesday, March 4 and 5, and the crowds of visitors put comfort out of the question, and rendered it a very difficult matter to carefully inspect any particular display. A part of the space was filled with competitive exhibits of hyacinths, tulips, and alpines, and daffodils were in great force, as the Daffodil Committee held its first meeting of the year on this occasion. Orchids were not numerous, but forced flowering shrubs, alpines, and greenhouse plants were very much in evidence, while Messrs. Carter's spring garden was greatly admired for its beauty and novelty. There were very few new plants.

FLORAL COMMITTEE.

A beautiful lot of perpetual carnation flowers from Mr. H. Burnett, Guernsey, attracted a great deal of attention; Marmion, Geisha, Mrs. C. F. Raphael, and R. F. Felton were varieties grandly displayed. Mr. G. Engelmann, Saffron Walden, had carnations forward, and showed the yellow Sunstar and Elektra finely. He also showed a large number of coloured forms of freesias under the general name of Freesia Ragionesi; some almost blue and others quite deep rosy-red.

A little group of perpetual carnations, set up by Messrs. Young and Co., Hatherley, contained good flowers of Geisha, Rose Dore, Mrs. C. W. Ward, Duchess of Devonshire, Winsor, and Mrs. Brodie Henderson, the latter an art red shade. Carnations Mary Allwood, White Wonder, Scarlet Glow, and La Rayonnante were varieties especially well shown by Messrs. Allwood Brothers, Haywards Heath. Messrs. Stuart Low and Co., Enfield, put up perpetual carnations in great variety, showing Baroness de Brienen freely and well, cyclamens, heaths, and azaleas.

A particularly striking exhibit from Messrs. Jas. Carter and Co., Raynes Park, represented a spring garden. A paved pathway occupied the centre, leading to handsome iron gates supported by ivy-clad pillars. Beyond the gates could be seen masses of golden crocuses beneath conifers, and hidden lights gave the effect of sunshine. On either side of the gates extended a low yew-backed terrace covered with daffodils and crocuses in great variety. In the terrace wall saxifragas were growing. In front of the wall a grass lawn of the most lovely velvety green extended, and jutting into this from the terrace wall was a semi-circular projection, carrying a grand leaden vase filled with blue hyacinths and with purple crocuses round the base. To right and left of the paved walk were beds of pink tulips and white crocuses. The exhibit was a great attraction, and excited a great deal of attention.

Just inside the entrance Messrs. Barr and Sons arranged a little rock garden display that was gay with Chionodoxa Lucilæ, Scilla sibirica, Muscari botrioides alba, Narcissus minimus, N. minor, N. Bulbocodium, N. triandrus, and N. cyclamineus. Fritillaria citrina, Epimedium rubrum-luteum, Saxifraga oppositifolium, and S. apiculatum were also well shown. Messrs. Sutton and Sons, Reading, exhibited hyacinths set in ferns. The spikes were pleasingly grouped—blue and buff, blush and rose, yellow and rose-red, and white and blush. Each grouplet was of semi-circular form.

A very fair collection of hyacinths was staged by Mr. A. Hewlett, gardener to Mrs. Balfour, Langley Lodge, Headington Hill, Oxford; of General Butler, Jacques, Captain Boyton, La Grandesse, Coreggio, and Electra there were fine spikes. Messrs. Carter Page, and Co., London Wall, presented a mixed collection of daffodils, hyacinths, tulips, and lily of the valley, all grown in bowls of fibre; the collection proved very interesting, especially to the ladies. Spanish irises from Mr. R. d'E. Day, Sutton Scotney, were very showy, and a good collection of varieties was displayed.

A very extensive exhibit of hyacinths, probably the largest ever seen at the Hall, was staged across the end of the hall by Messrs. R. and G. Cuthbert, Southgate. The hyacinths were in pans of five or eight plants, each pan containing but one variety. There were some scores of pans, and a few leading sorts were Schotel, pale blue; King Menelik, deep purple-blue; Lady Derby, pale rose; Perle Brilliant, porcelaine blue; Queen of the Pinks, rose-pink; Mr. Plimsoll, white; King Alfred, bright blue; Yellow Hammer, yellow—this gained a gold medal from the Dutch Bulb Growers' Society.

A very fine exhibit of a hundred and eighty hyacinths in pots, was set up by Mr. E. Beckett, V.M.H., gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree. The spikes were of fine size and substance, and particularly massive were the varieties Dr. Lieber, Queen of the Pinks, Jacques, Leviathan, King of the Blues, Schotel, Lord Balfour, Lord Derby, and Yellow Hammer. High cultural skill characterised this extensive display, and the gold medal of the General Bulb Growers' Society of Holland was well merited.

In these days, when the alpine plants have gained such a prominent position in horticulture, it was a treat to see such a splendid amateurs' display as the one staged by Sir Everard A. Hambro, K.C.V.O., Hayes Place, Hayes, Kent (gardener, Mr. J. Grandfield). The exhibit was worthy of the reputation of the exhibitor, the background being formed with flowering examples of Cytisus Kewensis, kalmias, and conifers, while nestling in pans amongst sandstone and moss were saxafragas in variety, flowering without signs of overforcing. These included Saxifraga scardica obtusa, S. Burseriana tridentata, S. Boissieri, S. Faldonside, S. H. S. Godseff, S. Burseriana Gloria in splendid form, S. Boydi, and S. longifolia; Primula Winteri, Viola gracilis, Omphaloides Cappodocca and a few tulips. The whole were in perfect health, but the arrangement could hardly be described as natural. With the shrubs in the background, daffodils of sorts were freely associated, and as hardy primulas were present in great force the group had a very spring-like effect.

A particularly fine exhibit of alpines, arranged in a low rock garden form, with the plants bedded in small granite chips, was a great success, and such exhibits are likely to increase the love of these beautiful plants. There were splendid breadths of Saxifraga oppositifolia alba, the fine yellow S. Faldonside, S. Boydi alba, S. oppositifolia splendens, S. Burseriana Gloria, shown grandly, S. Rocheliana, and S. Elizabethæ. This contribution was from Mr. Clarence Elliott, Six Hills, Stevenage. Dwarf conifers from Messrs. W. Fells and Sons, Hitchin, included capital plants of Juniperus sabina variegata, and J. nana canadensis aurea, both suitable for the rock garden.

A pleasing exhibit in rock garden fashion was contributed by Messrs. R. Wallace and Co., Colchester. Quite naturally grouped were the patches of Primula rosea, P. Juliæ, with bluish-purple flowers; Fritillaria meleagris, Saxifraga apiculata, S. oppositifolia splendens, S. Faldonside, Primula nivalis, Cheiranthus Allioni, Tulipa Clusiana, and T. Kaufmanniana. A very pretty exhibit of alpines from Mr. Maurice Prichard, Christchurch, contained a splendid lot of Primula denticulata, P. Cashmeriana, and P. cortusoides, Tritelia uniflora, Saxifraga decipiens, Rob Roy, and Cytisus præcox.

Yet another rock garden exhibit, and this a bold one, was disposed by Messrs. John Piper and Sons, Bayswater and Barnes. It was a bold design, and Primula Winteri, P. rosea, P. frondosa, P. denticulata, and its white form, and P. megasæfolia were prominent subjects used. Messrs. J. Cheal and Sons, Crawley, were exhibitors of alpines, primulas, and useful dwarf shrubs for rockwork planting. Messrs. T. S. Ware, Feltham, filled a narrow rock garden with Saxifraga oppositifolia, Erysimum helveticum, Primula Cashmeriana, the very pretty Thalictrum anemonoides, Saxifraga Faldonside, etc.

Mr. Jas. Box, Lindfield, filled a corner with a rock garden, wherein primulas were in great form, and many other alpines were well displayed. The Burton Hardy Plant Nurseries, Christchurch, contributed a small collection of alpines. Mr. L. R. Russell, Richmond, sent up hardy primulas and shrubs. A bright group of alpine plants was contributed by Messrs. J. Jackman and Son, Woking, and Messrs. J. Peed and Sons, Norwood, also exhibited plants suitable for the rock garden.

The Wargrave Plant Farm, The Arcade, Liverpool Street, showed some good colonies of saxifragas, hepaticas, scillas, and primulas, and had a pan of Mazus rugosus, a tiny plant with a fairly large flower that is chiefly composed of a large three-lobed rosy-purple lip, with a white, brown-spotted crest (A.M.). Mr. G. Reuthe, Keston, submitted a large collection of alpines, gay anemones, ericas, rhododendrons, Drimya Winteri, camellias, and irises.

Messrs. Baker's, Wolverhampton, exhibited Primula denticulata in variety, Sisyrinchium grandiflorum, and its rosy form. Coloured primroses and heaths were the chief features of the exhibit from Messrs. G. and A. Clark, Dover. Mr. A. Hemsley, Crawley, had an interesting collection of alpines and small shrubs: lithospermums, violas, and Potentilla Miss Willmott were well shown on a little rockery.

The group of forced shrubs from Messrs. James Veitch and Sons, Chelsea, was a pleasing one, composed largely of the graceful Wistaria sinensis and W. sinensis alba, associated with lilacs, Azalea Anthony Koster, Erica Veitchi, Rhododendron The Countess, Spiræa confusa, and Cerasus Hisakura. Messrs. A. Koster and Sons, Boskoop, showed their new lilac, a bright rosy lilac variety named Hugo Koster (A.M.)

A delightfully fragrant exhibit of violets from Messrs. Blackmore and Langdon attracted the ladies: La Belle Parisienne, Kaiser Wilhelm, and Lady Hume Campbell were the three varieties that appealed most to us.

Particularly fine in Messrs. W. Cutbush and Sons' group of carnations was a grand vase of the yellow-ground fancy Mrs. Waldorf Astor; Mrs. L. Mackinnon, red, and R. F. Felton, blush, were other varieties finely staged. The same firm presented a showy group of forced flowering trees and shrubs, the chief subjects being lilacs, mollis azaleas, magnolias, wistarias, and laburnums. Cinerarias from Messrs. James Veitch and Sons, Chelsea, were very effective, especially the elegant Feltham Beauty strain. Matador, Snowball, and Intermediate Blue formed the national colours respectively, red, white, and blue.

Messrs. H. B. May and Sons' exhibit included a pair of large graceful specimens of Asplenium caudatum, and batches of Gymnogramma gloriosa schizophylla and Nephrolepis Marshalli compacta. Messrs. H. Cannell and Sons, Swanley, sent a large batch of cinerarias.

ORCHID COMMITTEE.

Mr. E. H. Davidson, Orchid Dene, Twyford, contributed Brasso-cattleya Dora with a large and beautiful cream-white flower; Odontioda Zephyr-marginata, with purple margin round its reddish flowers; and Odontoglossum Ruby, a deeply-coloured O. Rossi hybrid. Messrs. Hassall and Co., Southgate, had some finely spotted odontoglossums, Brasso-cattleya Menda, and B.-c. Queen Alexandra.

Some quaint and interesting orchids from Gatton Park, Reigate, were staged by Mr. Collier, gardener to Sir Jeremiah Colman, Bart.; Dendrobium bigibbum Lady Colman (A.M.), with deep blush flowers; Cirrhopetalum picturatum, and the white Dendrobium speciosum fusiforme were a few of the kinds shown.

Messrs. J. Cypher and Sons, Cheltenham, had a pretty group in which Cypripedium aureum Hyeanum, Angræcum sesquipedale, Odontioda Bradshawiæ, and Dendrobium nobile virginale figured conspicuously. The charming and graceful Angræcum citratum was very well represented in the group of orchids submitted by Messrs. Charlesworth and Co., Haywards Heath; Odontoglossum Elaine, O. Jasper, Phaius tuberculosus, and the deep crimson-red Odontioda Patricia were other good things on view.

Cymbidium insigne, Odontoglossum Thompsoni, Brasso-cattleya Maronæ, Odontioda Bradshawiæ, Renanthera Imschootiana, and fine varieties of Cattleya Trianæ were all capitally shown by Messrs. Sander and Sons, St. Albans. Cattleya Trianæ Colossal, a fine bright purple-mauve variety with very broad sepals and petals, gained an A.M. for Mr. Alexander, orchid grower to Sir George Holford, Westonbirt, Gloucester.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, displayed Lælio-cattleya Pizzaro with five showy, purple and gold flowers; a long spike of the black and green Cœlogyne pandurata, various dendrobiums, and the tiny and rare Dendrobium linguæforme. Odontioda Bradshawiæ, Cookson's var., was capitally shown by Mr. H. J. Chapman, gardener to Mrs. Norman Cookson, Oakwood, Wylam-on-Tyne.

Sophronitis grandiflora Cobb's var., with large flowers of very vivid vermilion colour, was sent by Walter Cobb, Esq. (gardener, Mr. C. J. Salter), Rusper, Horsham. Mr. Balmforth, gardener to F. Menteith Ogilvie, Esq., The Shrubbery, Oxford, exhibited Odontioda Bradshawiæ Shrubbery var., a glorious rich crimson form with large blooms.

Messrs. J. and A. McBean, Cooksbridge, showed Cattleya Tityus Excelsior, with a beautiful lip; L.-c. Smilax Prince of Orange (A.M.), with deep orange-coloured flowers; and Odontoglossum eximium Alpha (F.C.C.), rosy, with deep red-brown blotches. Miltonia Harwoodi, Moss' var. (A.M.), with rich velvety salmon-red flowers; and Odontioda Mossiæ (Cochlioda Noezliana and Odontoglossum maculatum) (A.M.), were shown by J. T. Moss, Esq., Wintershill, Bishop's Waltham.

A spike of the rare, purple-flowered Eulophiella Peetersiana and a beautiful specimen of Sophro-lælia Psyche, with about fifty reddish-scarlet flowers, came from Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking.

NARCISSUS AND TULIP COMMITTEE.

Mr. Christopher Bourne Simpson, Bletchley, had a charming display of choice daffodils, and the group contained many fine things. There were Whitewell, Lord Roberts, Sister, Mervyn, the Golden Cornelia, Bernardi, the graceful Incognita, Olympia, Evangeline, George Herbert, and a beautiful seedling with broad, salmon-tinted buff cup and white perianth segments that are coloured at the base; this is a Leedsi form, and has been christened Wendy. Messrs. R. H. Bath, Lim., Wisbech, exhibited tulips and daffodils growing in fibre, and thus added to the popularity of this method of culture. Crocus and daffodils were also well shown, but Aspasia in bowls was the chief attraction.

Messrs. Barr and Sons, Covent Garden, exhibited a goodly set of daffodils, the flowers all fresh and beautiful. King Alfred, Victoria, Sunrise—very pretty—Hamlet, Duke of Bedford, Cardinal, and the bright orange-coloured Firelight were a few of the best, but there were several dainty unnamed seedlings on view. The daffodils from Messrs. J. R. Pearson and Sons, Lowdham, Notts, were well set up, but a trifle small. Some outstanding varieties were Blackwell, Victoria, Lady Margaret Boscawen, the very dainty Vega, King Alfred, the brilliant little Firebrand, Duke of Bedford, and Scarletta.

A slightly crowded but otherwise fine exhibit of daffodils staged over a base of Isolepis gracilis by Messrs. Cartwright and Goodwin, Kidderminster, was keenly inspected by daffodil lovers. Fairy, King Alfred, Bennett Poe—very graceful—Arnold Rogers, the lovely Incognita, Lady M. Boscawen, Firebrand, Circlet, Mdme. de Graaff, and Southern Light were a few of the best sorts. Messrs. Walter T. Ware, Lim., Inglescombe, brought up a few first-rate daffodils forced in pots; a few leading varieties were Miss Willmott, Harold Finn, Duke of Bedford, White Nun, Princess Alice, Queen of the West, Leo—a fine trumpet variety—and Macebearer. A pretty little exhibit from Robert Sydenham Limited, Tenby Street, Birmingham, consisted of lily of the valley, freesias, and daffodils; the latter included Great Warley, Ursula, Lord Kitchener, Castill, Marjorie, King Alfred, and Pilgrim.

CERTIFICATE AND AWARDS.

First Class Certificate.—To Odontoglossum eximium Alpha, from Messrs. J. and A. McBean, Cooksbridge.

Award of Merit.—To Dendrobium bigibbum var. Lady Colman, from Sir Jeremiah Colman, Bart. (gardener, Mr. Collier), Gatton Park, Reigate; to Miltonioda Harwoodi Moss' var., and to Odontioda Mossiæ, from J. T. Moss, Esq., Wintershill, Bishop's Waltham; to Lælio-cattleya Smilax var. Prince of Orange, from Messrs. J. and A. McBean; to Cattleya Trianæ Colossal, from Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury; to Oncidioda Cooksoni Ralli's var., from P. Ralli, Esq., Leatherhead; to Lilac Hugo Koster, from Messrs. Koster and Son, Boskoop, Holland; to Saxifraga Faldonside, from Sir E. Hambro (gardener, Mr. Grandfield), Hayes; to Mazus rugosus, from the Wargrave Plant Farm, The Arcade, Liverpool Street, E.C.

MEDALS.

Silver-gilt Flora.—To Messrs. Jas. Carter and Co., Raynes Park, for a spring garden.

Silver-gilt Banksian.—To Mr. Christopher Bourne, Bletchley, for daffodils; to Messrs. J. Piper and Son, Barnes, for alpines and hyacinths; to Messrs. J. Veitch and Sons, Chelsea, for greenhouse plants and shrubs.

Silver Flora.—To Messrs. W. Cutbush and Son, Highgate, for forced shrubs and carnations; to Mr. Clarence Elliott, Stevenage, for alpines; to Messrs. R. Wallace and Co., Colchester, for hardy plants; to Messrs. Barr and Sons, Covent Garden, for daffodils; to Messrs. Cartwright and Goodwin, Kidderminster, for daffodils; to Messrs. Sander and Sons, St. Albans, for orchids.

Silver Banksian.—To Messrs. Allwood Brothers, Hayward's Heath, for carnations; to Mrs. Balfour, Headington, for hyacinths; to Mr. Jas. Box, Lindfield, for hardy plants; to Mr. Burnett, Guernsey, for carnations; to Messrs. G. Jackman and Son, Woking, for hardy plants; to Messrs. S. Low and Co., Enfield, for carnations, etc.; to Messrs. H. B. May and Sons, Edmonton, for ferns; to Messrs. J. R. Pearson and Sons, Lowdham, for daffodils; to Messrs. Walter T. Ware, Lim., Inglescombe, for daffodils in pots; to Messrs. Charlesworth and Co., Haywards Heath for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; and to Messrs. S. Low and Co., Enfield, for orchids.

Bronze Flora.—To Messrs. Blackmore and Langdon, Twerton-on-Avon, for violets; to Messrs. J. Cheal and Son, Crawley, for rock garden; to Mr. C. Engelmann, Saffron Waldon, for carnations and freesias; to Mr. M. Prichard, Christchurch, for hardy flowers; to Messrs. Carter Page and Co., London Wall, for hardy plants; to Mr. G. Reuthe, Keston, for alpines, etc.

SPRING SHOW OF BULBS AND ROCK PLANTS.

This exhibition, though perhaps not so large as we have seen it on former occasions, was, however, a good one. The hyacinths, being particularly good in this season of reputed poor bulbs, both the trade and amateurs staging large, well-developed spikes. It is somewhat strange that the exhibitors cannot drop the old exhibition pot, and stage them in the pots they are actually grown in.

The prizes for eighteen hyacinths distinct were keenly contested, the first prize exentually being awarded Mr. J. H. Barker, gardener to Mr. F. R. Dixon Nuttall, J.P., Ingleholme, Ecclestone Park, Prescot, Lancs, who staged some beautifully developed spikes and even throughout. The varieties were: Jacques, Perle Brilliant, La Grandesse, Menelik, Cornelia, Correggio, Enchantress, Ivanhoe, Gounod, La Victorie, a grand spike, Lady Derby, Electra, Queen of Pinks, M. Van der Hoop, Marconia, King of the Blues, Yellow Hammer, and Cardinal Wiseman. Mr. J. Gibson, gardener to the Duke of Portland, K.G., Welbeck Abbey, Worksop, was placed second with a slightly weaker exhibit, though he had some splendid spikes, the best being Jacques, Perle Brilliant, La Victorie, King of the Blues, Totula, Moseno, and Lady Derby. It might be that Mr. Gibson lost a point or two in staging. Mr. A. Hewlett, gardener to Mrs. Henry Balfour, Headington Hill, Oxford, secured the third position with flowers much more open in the spike, while Mr. G. Craddnck, gardener to Colonel the Right Hon. Mark Lockwood, Bishop's Hall, was fourth with some good spikes, while others were past their best.

For twelve distinct varieties Mr. H. Prime, gardener to the Marquis of Salisbury, Hatfield House, Hatfield, was a fine first-prize winner. The flowers, though being fully developed, were wonderfully fresh and bright. A few of the best were Electra, Jacques, King Menelik, La Victorie, Lady Derby, and Moreno. Mr. H. Roper, gardener to Mr. R. G. Morrison, The Hollies, Victoria Park, Wavertree, was a capital second, with a point or two in his favour in the matter of staging; he had excellent spikes of Jacques, La Victorie, King of Blues, Menelik, and Gounod. Mr. T. F. Weddle, gardener to Mr. H. G. Tyson, Hollybush Lodge, Avenue Road, Old Southgate, was third with fine examples, but one or two were a little past their best. Mr. W. H. Newton, gardener to Mrs. McDowell Nathan, Little Heath Wood, Potter's Bar, was a creditable fourth.

There were five entries for six hyacinths, distinct, the first prize going to the North, which was well won by Mr. A. Hanson, Ivanhoe, Victoria Park, Wavertree. The varieties were Jacques, Perle Brilliant, Menelik, Marconi, La Victorie, and Correggio, all fine examples. Mr. J. Skelton, gardener to Lord Hillingdon, Wilderuesse, Sevenoaks, was a good second with fine spikes of La Victorie and City of Haarlem; while Mr. H. Edwards, gardener to Mrs. Arthur Levita, Norton Priory, Chichester, was third.

There were four contestants for four pans of hyacinths, ten roots of one variety in each pan, and the first prize fell to Mr. G. T. Weddle, who had timed his varieties splendidly. The spikes were beautifully fresh, clean, and bright. The varieties employed were Schotel, pale blue; City of Haarlem, yellow; La Victorie, red in splendid form; and Correggio, white. Mr. J. Gibson was a fine second, using the same varieties except in the blues, where he employed the dark King of the Blues. Mr. H. Prime was third with fine examples of Brilliant and Lady Derby; while the fourth position fell to Mr. G. Cradduck, who was let down with his pan of Menelik.

There were two entries for the finest decorative display of hyacinths, the first award being the Gold Medal of the General Bulb Growers' Society of Haarlem. This was secured by Mesrs. R. and G. Cuthbert, Southgate, who occupied the entire end of the hall with pans containing seven to ten spikes each; these were arranged in three tiers, and made a magnificent display, as sixty-five varieties would do. The chief sorts were La Victorie, Totula, King of the Violets, King Alfred, Ivanhoe, King Menelik, Jacques, Cardinal Wiseman, Queen of the Pinks, King of the Roses, Correggio, La Grandesse, Mr. Plimsoll, Yellow Hammer, and City of Haarlem. Messrs. J. Piper and Son, Bayswater, were second with a nice display

in baskets, the groundwork being moss, with Selaginellas dotted in between, while palms and adiantums considerably added to the display.

For six single hyacinths grown in moss fibre, in vases not exceeding six inches in diameter, there were three competitors. Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham Common, winning first prize with nice clean spikes. Miss Gordon Thompson, The Elms, Potter's Bar, was second, and the Hon. Mrs. Guy Baring, St. Cross Mill, Winchester, third.

The tulips in moss fibre were excellent; the vases not exceeding seven inches in diameter gave sufficient room to display each variety to perfection. Mr. W. Howe secured the first prize with splendid vases of La Rêve, Prince of Austria, Keizerskroon, Montressor, Van der Neer, and Vermilion Brilliant. The Hon. Mrs. Guy Baring was second with well-developed bowls. Miss Gordon Thompson was third. Strange to relate, there were but two exhibitions for six bowls of narcissi, Mr. W. Howe again securing the premier honours with vases timed to perfection. The varieties were Seagull, Mrs. H. J. Veitch, Golden Bell, Lilian, Lucifer, and Will-o'-the-Wisp. The Hon. Mrs. Guy Baring was second.

The Gentian Cup offered by Messrs. R. Wallace and Co. for the best exhibit of alpines, bulbs, and dwarf shrubs, arranged on a space 5ft. by 3ft., brought out but one competitor, Mr. Grandfield, gardener to Sir Everard Hambro, Hayes. The exhibit was crowded between some trade displays in the annexe, and consequently seemed rather poor. It contained Cytisus Kewensis, Viola gracilis, and such fine saxifragas as Faldonside, Burseriana Gloria, apiculata, Petrarchi, Elizabethæ, Frederici Guilelmi, with primulas, etc.

NEW BOOKS.

FRUIT GROWING FOR BEGINNERS.

By F. W. Hardy. ("Country Life," Lim., 20, Tavistock Street, Covent Garden, London, W.C.) Price 1s.; cloth, 1s. 6d.

The author tells his readers in the admirably written preface that "Fruit Growing for Beginners" has been written with the object of supplying amateurs with a handbook on fruit culture that is at once concise and simple; and that he has succeeded in effecting his object there can be no doubt. He has accomplished something more than this, for while constantly keeping in view the requirements of the amateurs who engage in fruit growing with but little practical knowledge of the details, he has succeeded in making the book of much value to those who have made some advance in this interesting branch of garden work.

It would be a pleasant task to write at length on this interesting and useful book, but it must suffice to say that all classes of hardy fruits that are usually grown in the garden are included and dealt with in such manner that the amateur will have no difficulty in obtaining a clear idea of the course of procedure essential to success.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

OBITUARY.

MR. WILLIAM COCKER.

Keen regret will be evinced by horticulturists generally, and rose lovers in particular, on learning of the demise, at the comparatively early age of 55, of Mr. William Cocker, senior partner of the firm of Messrs. James Cocker and Sons, Springhill Nursery, Aberdeen, which took place at his residence, Springhill, near Aberdeen, on Thursday, February 27. He had been in indifferent health for a considerable time, and, hoping that a change might be beneficial, he went to Harrogate in the late autumn of last year, but it proved otherwise. Born on a nursery, the son of a nurseryman, and the grandson of a nurseryman, the love of his profession was instinctive. From a boy at school, the study of rose culture had always a keen fascination for him, and as he grew older he studied the scientific side of horticulture. In the early '70's his father sent him to Forest Hill, London, to engage for a period with Messrs. James Laing and Sons, where he studied rose culture. From thence he proceeded to Slough Nurseries, under the late Mr. Charles Turner. On the completion of his apprenticeship he returned to Aberdeen to assist his father, and enter upon his life's work. How well he accomplished his task is well known. In his rose work, Mr. Cocker considered that most beautiful rose, Mrs. James Cocker, one of his greatest triumphs, and he named it after his mother. The most recent triumph of the firm was the fine rose Mrs. Andrew Carnegie. It has been stated in various quarters that this rose was the work of Mr. William Cocker, but this is not the case. Its production was due to his brother, Mr. Alex. M. Cocker.

As a hybridist, Mr. Cocker did some capital work, especially among polyanthuses, and the Royal Horticultural Society awarded him a certificate of appreciation for his work in raising double varieties from seed.

Mr. Cocker was not married, and the charge of the business—as has been the case for the past twelve months—will now devolve upon his surviving brother, Mr. Alex. M. Cocker.

THE LATE MR. W. COCKER.

DAHLIAS TO PERFECTION.—A thorough guide to the successful culture of these popular flowers is "Dahlias and their Cultivation," by J. B. Wroe, price 1s. net, by post 1s. 2d., bound in cloth 1s. 6d., by post, 1s. 8d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

THE R.H.S. FORTNIGHTLY SHOWS.

As a constant visitor to these shows all the year round, I have read the remarks of your correspondent "Corrigenda" with considerable interest, for the points raised have been pretty widely discussed at the last few meetings, and no doubt when the spring flowers come in with a rush, the discussions will become more acute. The exhibitors want more space for their displays; the visitors are clamouring for more room so that they can see the exhibits, while there is a section who attend chiefly to see their friends, and, to my way of thinking, block the gangways to their hearts' content. And those of us who remember the sign posts and blind alleys that were tried a few years ago to lessen the evil of filling up the gangways, had good cause to be thankful when they were removed.

I quite agree with your correspondent as to the monotony of the rock gardens, but is it not a sign of the popularity of this class of gardening? Some of the exhibitors do not stage their exhibits just for the "fun of the thing," and if some of the exhibits staged are not up to the "hall mark," they are generally the best the grower can produce. Sometimes it is a new exhibitor who is anxious to stage at Vincent Square; in such a case it would be very hard on him if his exhibit were rejected, for the chances are the second time he turned up a great improvement would be apparent. So I fear "Corrigenda's" censorship is out of the question; and, to my way of thinking, if the shows were classified it would not mend matters one bit; on the contrary, it would lessen the interest taken in them. The great variety they now possess is part of their charm, for there is something to please the tastes of everyone, and the idea of cutting an exhibitor down to one show per month would cause havoc amongst the narcissi exhibitors, dahlia exhibitors, and all kindred subjects, for it would mean they could perhaps only put in an appearance once a year; and I am strongly against reducing the size of the large exhibits. What figure would a group of forced shrubs cut in a ten-foot run of space; a collection of fruit trees in pots; or the grand displays of bamboos? What would they look like? The superintendent has a very difficult task to perform now, cutting down spaces wherever he can, without spoiling the effect of the show, or keeping away exhibitors.

But I do think it time the "off season" finished, much as I like pictures to admire and please the eye, and much as I am devoted to pickles, jam, and marmalade ad lib on the table at meal times, I do not think they should monopolise the main hall and crowd out the floral exhibits into the annexe. But there, I suppose all of us have our grievances, and no doubt the council are fully cognisant of the limiting of spaces to exhibitors, and the cramped gangways; but, unfortunately, they cannot push the outer walls, either into the playground of the school on the one hand, or the technical school on the other, much less the playing-field of the Westminster School in the front; so some further solution will have to be suggested.

I think that your correspondent should bear in mind that all the horticultural interests of the kingdom (and they are many) look upon the "Hall" as a meeting-place, both amateur and trade alike, so this in itself forms some congestion of traffic. In fact, there are so many interests bound up in the letters R.H.S. that it has become a sort of magnetic pole which attracts the horicultural world each fortnight; and I am

afraid the protest and remedies suggested by "Corrigenda" will do little, if anything, to arrest the present condition of affairs—in fact, I have fully made up my mind that matters will get worse during the coming season instead of better. Essex.

"Corrigenda" in last week's issue raises a very interesting question, but I am afraid he is not a "builder of rockeries" at the meetings, or he would appreciate the difficulty of making any great variation in the formation of them when confined to table-space of three feet width. There is certainly a great improvement this year, as the authorities have allowed some firms the whole width of the double staging, and how much it adds to the beauty of the show! Before, all one could see on entering was a mass of faded green baize, but now they have gone so far, why not let exhibitors use the floor for rockeries if they wish? Those who prefer a background could put one up for themselves. With regard to the small space allowed for visitors, it might be as well if the Council put on the cards whether it was to be a flower show or a rival to the Royal Academy. At present we do not know to which we are going. F. R. H. S.

FORTHCOMING ENGAGEMENTS.

MONDAY, March 10.—United Horticultural Benefit and Provident Society.
TUESDAY, March 11. Surbiton Spring Show.
WEDNESDAY, March 12.—Clevedon Spring Show.
North of England Horticultural Society's Spring Show, at Bradford.
THURSDAY, March 13.—Torquay Spring Show.
TUESDAY, March 18.—Royal Horticultural Society; Narcissus Committee meets at 11.30 a.m.; Fruit, Vegetable, and Floral Committees at 12 o'clock; Lecture at 3 p.m. on "The Romance of Weeds," by Mr. R. Lloyd Praeger, B.A.; Scientific Committee at 4 o'clock.
SATURDAY, March 29.—Paisley Spring Show.

CATALOGUES RECEIVED.

THE WHINS, CHALFONT ST. PETER, BUCKS.—A very novel catalogue of plants that have silvery or grey foliage. The covers are silvery, and so the title of "The Silver List" is justified.

A. PERRY, HARDY PLANT FARM, ENFIELD.—Lilies, montbretias, gladioli, and seeds of perennial plants form the subject matter of the new issue, and many uncommon species are included.

ANSWERS TO CORRESPONDENTS.

RASPBERRIES FOR MARKET CULTIVATION.—F. G., Hants: Could you please tell me in your "Answers to Correspondents," the two best varieties of raspberries besides Superlative to grow for market?—For comparatively dwarf varieties, a true stock of Carter's Prolific and Norwich Wonder are considered most profitable for market gardening, and these need not be staked. In addition to Superlative, the two tall varieties (needing stakes or wires) most suitable for a market grower are Hornet (Rivers') and Baumforth Seedling.

THE LATE MR. WM. HOLMES.—A. C. B., Forest Gate: Will you kindly give me, through your "Answers to Correspondents" column, the date of the decease of Mr. Wm. Holmes, who was for so many years secretary of the National Chrysanthemum Society? I think it must be about twenty-five years ago since he passed away, but as I have not any old Gardeners' Magazines convenient for reference I cannot fix the date.—Mr. Wm. Holmes died on Thursday, September 18, 1890; he was a nurseryman and the son of a nurseryman, and his business was at Frampton Park Nurseries, Hackney. In 1877, on the secretaryship of the Borough of Hackney Chrysanthemum Society becoming vacant, he was unanimously elected to fill the post, and the results more than justified the appointment. In 1877 the society had 52 members, an income of £84, and disbursed £53 in prizes. In 1883 he suggested that the society should change its name and become the National Chrysanthemum Society. This suggestion was adopted, Mr. Holmes was appointed hon. secretary of the new venture, and wonderful success followed. In 1889 the society had over seven hundred members and an income of about £850. In 1886 so great had been the progress made during the three previous years, that the members presented Mr. Holmes with three silver epergnes and an illuminated address as a mark of their appreciation of his efforts. Mr. Holmes was in his thirty-eighth year when he passed away.

ADDRESS.—J. S. H., Manchester: As requested, we have forwarded your letter to the desired address.

DAFFODIL CULTURE IN THE SCILLY ISLES.—M. E. J., Bristol: I am fairly well acquainted with the cultivation and distribution of daffodils by the growers in the Isles of Scilly, but I do not know how the industry came into being. Can you, briefly, tell me how the industry originated? — About 1865 there were eight varieties or species of narcissi growing in the Isles of Scilly, some of them in almost a wild state. These were N. Telamonius plenus, N. odorus major (Campernelli), N. Tazetta ochrolencus (Scilly White), N. Tazetta aureus (Grand Soleil d'Or), two varieties of Grand Monarque, N. biflorus fl. pl., and N. poeticus recurvus. These had been introduced in various ways, possibly by the monks at Tresco, probably by the Governors of the islands, and, in the case of the giant jonquil, by a sailor son. Besides these eight daffodils there were some few others in the gardens at Tresco, and the late Mr. Augustus Smith suggested his tenants should send flowers to Covent Garden, seeing they grew so well and flowered so early. He himself dispatched the first consignment in 1865, and his flowers realised £1. In those days, and for some time later, there was not a big demand for cut flowers, and, though daffodils were sent to Covent Garden from St. Mary's and Tresco, it was not until about 1880 that the business became really remunerative. In 1883 Mr. T. Algernon Dorrien-Smith went to Holland, Belgium, and the Channel Islands to study the daffodil industry and its possibilities, discovering that the Channel Islands growers were turning their attention to potatoes, grapes, tomatoes, and beans for the early markets, he felt that there was a good opening for Scilly daffodils, and so he bought bulbs largely for himself and for his tenants, and thus placed the industry on a firm basis. The exports of flowers rose to 65 tons in 1885, 85 tons in 1886, 160 tons in 1887, 188 tons in 1888, and 198 tons in 1889.

CLIMBING ROSES IN POTS.—H. A., Taunton: At the end of last October I dug up and placed in large pots several dozen rambling roses. These were plunged in the open ground until the middle of January, when they were lifted and placed in a cold house, where they receive plenty of ventilation. The weak shoots were cut out and the strong ones shortened slightly. I wish to have them all in bloom by the middle of May. When should I place them in heat, and what should their treatment be while in heat? At present they have shoots well over an inch in length.—At this date it is quite impossible for us to say how much heat your roses should receive to produce flowers in mid-May, because we do not know what kind of weather lies before us. Do not attempt to force the plants by the use of much heat. Keep a little warmth in the pipes, so that plenty of ventilation may be allowed. Avoid cold draughts, and do not let the night temperature fall below 45 degrees. In bright, mild weather gently spray the plants during the morning, and by carefully damping down produce an atmosphere that suggests a pleasant day at the end of April. By the middle of April you will be able to obtain a good idea of the possible date of flowering, and will then be able to judiciously retard or accelerate progress as seems necessary.

NAMES OF PLANTS.

M. A., Ware.—1, Acacia armata; 2, A. Drummondi.

W. F. A., Poole.—1, Orobus vernus; 2, Saxifraga oppositifolia; 3, Cœlogyne flaccida.

F. M. N., Chippenham.—1, Ceropegia Woodi; 2, Libonia Penrhosiensis; 3, Mimulus (or Diplacus) glutinosus.

J. L. C., St. Asaph.—Eriostemon buxifolius; 2, Polygala myrtifolia grandiflora—commonly known as P. Dalmaisiana.

S. S., Ryde.—1, Cedrus atlantica glauca; 2, Retinospora obtusa; 3, Alyssum saxatile; 4, Ribes sanguineum; 5, Dendrobium Pierardi.

NEWS FROM HEADQUARTERS.

COST

The cost of labour in your garden is just as high whether you plant low-grade seeds or Carters Tested Seeds.

And when you come to reflect upon the fact that the capacity of your garden is limited and that unless you are sure of your seeds the long months of waiting may end in disappointment, the difference in cost is so trifling, the difference in results is so great.

Carters Tested Seeds, produced under conditions which have for their aim the continuous and unbroken betterment of the species, MUST be worth incomparably more than the seeds offered by the mere seed-vendor, who has no facilities for testing and cross-fertilisation. And yet most of Carters Tested Seeds may be had in 3d., 6d., or 1s. packets—prices within the reach of everybody who has a garden.

Even the smallest orders are handled with the same courtesy as orders running into hundreds of pounds.

Why not run down to Raynes Park and see us at work in our warehouse and trial grounds? There is always something of interest to see.

Open at all times, to customers and non-customers alike.

CANARY GUANO

FOR GARDEN AND GREENHOUSE.

There is no Fertilizer equal to Canary Guano for the Garden and Greenhouse. Compare its results, its analysis, and its fine condition with any others, and you will be convinced of this. Canary Guano immensely improves the colour and size of all Flowers, and doubles the yield of all Fruit and Vegetables. It is particularly suited to lawns, golf greens, and cricket grounds. Canary Guano is manufactured by The Chemical Union, Ltd, in conjunction with their associated company, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, who are the largest Special Fertilizer Manufacturers, and whc goods are used all over the World.

CANARY GUANO is sold by Seedsmen, etc., in tins and bags, from **6d.** to **20s.**

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Coal.

Coal is so familiar and apparently commonplace a subject that we rarely give a thought to the underlying wonders which a careful study of it reveals. The garden lover who soars beyond the simple culture of hardy plants in the open, and whose pocket and inclinations permit him to deal with tender and choice exotics, recognises the fact that coal as a heating material is an essential as an indirect means of protection of these against the rigours of winter; but probably rarely recognises the fact that by its use he is really availing himself of a previous generation of plants whose remains are now yielding up their long-imprisoned sunshine in support of their present successors. The human mind, however, is totally incapable of estimating the chronological gap which lies between the two epochs. The great Book of Nature which lies beneath our feet, enshrined in the rocks which form the terrestrial crust, gives us glimpses of that inconceivable past during which the now dry land, or even lofty mountains, have alternately sunk into the profundities of deep oceans, and eventually risen anew therefrom into the realm of sunshine. Each of these changes is clearly proved, and is not the mere outcome of vague theory, as is evidenced in the familiar regions of Kent by the coal seams there underlying the chalk. This naturally leads to the questions, "What is coal?" and "What is chalk?" As regards the latter, we dealt with it recently under the title of "Lime" in one of our "Notes of the Week," in which we showed that it was essentially a deep ocean deposit which required myriads of years to be formed by the slow accretion of marine animal remains. Turn we now to the coal, and analyse it in similar fashion, and we find that the immense thickness of the coal measures is entirely due to a probably equally slow accretion of terrestrial plant remains, mostly of ferns and their allies. Again, for myriads of years, these plants occupied immense areas on more or less elevated, though presumably flat and swampy land, bathed probably in a constant humid atmosphere of tropical or subtropical temperature, and under a more or less clouded sky—i.e., in the most congenial conditions possible for such a class of growth. It is also reasonable to expect that in those far distant times the percentage of carbonic acid gas in the atmosphere was much greater than at present, since at that time all the solid carbon now locked up in our coal seams must have been held in suspension as invisible gas in the upper air. Profiting by these conditions, these fern forests grew luxuriantly generation after generation, rising up and dying down, each one in its decay contributing something to the underlying mass of vegetable débris, which was eventually solidified by its own and subsequent pressure into the coal we are using to-day, in which, and the associated shales or underlying soil, abundant evidence is found in the shape of the veritable frondage itself. Such specimens are often so perfect that we are quite able to compare them with present-day growths; and, singularly enough, though they date so far back that evolutionally they might be expected to be much simpler as an approach to their undoubted progenitors, the seaweeds of the primeval oceans, they are equally complex in structure and perfect in detail as their successors of to-day. One of the most curious features in connection with the coal formation generally is the successional character of the seams themselves, each one of which must represent a continuous forest of very long duration. In some parts of the world they occur in considerable numbers, one after the other, each one definitely separated by rocks formed of solidified clayey soil, shale, or even of other descriptions, the total thickness of such superimposed seams running into thousands of feet. This could only happen by each forest, in turn, becoming submerged, which can only mean a subsidence of the surface and consequent flooding. This, in its turn, must have brought suspended soil, and accumulated it until conditions were restored favouring fresh growth and the formation of another seam, the alternative being a rise of the land, which resulted in draining it sufficiently to effect the same results. Probably the successive seams are due to both causes, each involving very long periods, while the total period involved in subsequent deposits, and removal of deposits by denudation, since the coal-forming plants flourished on the surface, defies, as we have said, even an approach to computation.

MR. A. BULLOCK.

Mr. A. Bullock, head gardener to J. Wythes, Esq., at Copped Hall, Epping, for the past eleven years, has charge of an old and very interesting garden, and one which has been greatly extended during his service. Nothing is specialised in, but every effort is made to have each department up to date, and to maintain a supply of fruits, flowers, and vegetables all the year round. The gardens are especially well provided with a fine lot of glass-houses. Mr. Bullock, who is now well known in the Metropolitan district, was previously head gardener to the late Lady Howard de Walden, at West Malvern, and before that he was employed at Lockinge, Halton, and Dover House, consequently his experience has fitted him for the position he now occupies. He is a first-rate all-round gardener, a capable organiser, as exemplified by the work he has accomplished at Copped Hall, and a most genial companion. For some time past Mr. Bullock has had a seat on the Royal Horticultural Society's Fruit and Vegetable Committee, and his thorough

acquaintance with the various kinds of fruits and vegetables and their cultivation has obtained for him a high position among the members, consequently his judgment on the novelties that come before the Committe is treated with the highest respect.

Awards to Perpetual Carnations.—By arrangement with the Royal Horticultural Society the Floral Committee of the Perpetual-flowering Carnation Society will meet at Westminster four times a year, instead of twice as heretofore. The first of such meetings will be held on Tuesday, March 18, at 11 a.m. No novelty will be dealt with unless it is registered with the Society, and regulations regarding registration may be obtained from the Hon. Secretary, Mr T. A. Weston, Floradale, Orpington, to whom also application should be made for the schedule of the Leamington Carnation Show to be held on April 10 and 11.

Resignation of Sir Trevor Lawrence.—With reference to his impending resignation of the presidency of the Royal Horticultural Society, Sir Trevor Lawrence, Bart., writes: "In 1884, when I became president, the society had fallen into serious difficulties, pecuniary and other. But the surrender of the gardens at South Kensington laid the foundations of a new era. Since that time the society's progress has been uninterrupted, until it reached its present position of unprecedented prosperity and affluence. My reasons for writing this letter are the desire to emphasise the fact, fully recognised by my colleagues and myself, that the society's success has been due to the remarkable spread of a love of gardens and gardening among all classes of our people, rich and poor alike, and the fact that even this would not have sufficed to ensure prosperity had it not been decided to devote the society's energies wholly to the promotion and direction of scientific and practical horticulture, a decision which has been strictly adhered to. I cannot, however, resign a post, which has meant so much to me for so many years, without asking leave to express publicly my deep obligations to the colleagues with whom it has been my good fortune to work for so long. The society's council and committees are filled by men who know their work thoroughly, and are the heads of their special departments. They give gratuitously time, knowledge, and energy without stint to all they undertake. In this they have the hearty support of their employers, both amateur and professional, from whom, indeed, the society received a large measure of support even in its darkest days. The result may be summed up in a few words. The society, founded in 1804, has now upwards of 13,000 Fellows, a subscription income of over £19,000 a year, a hall which cost £45,000, a celebrated garden, with a horticultural school and laboratory, upon which £10,000 has been spent, an extensive and valuable library, a reserve fund approaching £70,000, and no debts. I should not omit a reference to the valuable services of the Rev. W. Wilks, our secretary for twenty-five years, to whom a well-deserved testimony is now being raised."

Colouring Matter in Plants.—For some considerable period Professor Keble, of the University College, Reading, and Messrs. E. F. Armstrong and W. N. Jones, have been engaged in the investigation of the colouring matter of plants, and have already obtained some interesting results. In their latest report to the Royal Society they state that according to the results they have obtained the latent colouring matter, or chromogen, becomes coloured under the influence of bodies that give it oxygen while the colours can be made to disappear under the influence of reducing agents. It was possible that this chromogen circulated in the plants, carrying oxygen to the tissues, and that it was only when it reached such parts as the petals where this work was not required, that the oxidation of the colouring matter became complete and the colour appeared. It seemed to depend on the greater or less quantity of water in the plant whether the oxidising or reducing agents gained the upper hand, and the authors suggested that the predominence of oxidation or reduction process might have an important bearing on such phenomena as the latency and activity of seeds and the awakening of plants from the winter rest.

Nicotine as an Insecticide.—Appreciating the importance of nicotine in combating insect pests injurious to fruit trees, the Kent fruit growers are urging upon the Government the desirability of abolishing the duty on the tobacco imported for the manufacture of insecticides, and they suggest that it should be rendered useless for smoking purposes by the addition of paraffin before it leaves bond. It is found that the concession already made by the Government in allowing tobacco to be grown for agricultural purposes free of Excise duty both in England and Ireland is of no practical value, seeing that nicotine costs more to grow than to buy.

Huntingdon Daffodil Show.—Miss P. M. Linton, the hon. secretary of the Huntingdonshire Daffodil Society, writes that, owing to the earliness of the season, the Society's exhibition will be held on April 3, instead of on April 17, as previously arranged.

Memorial to Sir Joseph Hooker.—A mural tablet of coloured marble has been placed in Kew Church in memory of this distinguished botanist, and occupies a position on the north wall close to the memorial of Sir W. J. Hooker. On the tablet is the following inscription: "1817-1911 Joseph Dalton Hooker, O.M., G.C.S.I. C.B. M.D. D.C.L. LL.D., Associé Etranger of the Institute of France, Knight of the Prussian Order "Pour le Mérite," sometime President of the Royal Society, for XX years Director of the Royal Botanic Gardens Kew. Born at Halesworth 30th June 1817, died at Windlesham 10th Dec. 1911. The works of the Lord are great sought out of all them that have pleasure therein." Underneath the inscription is a Wedgewood medallion portrait of Sir Joseph Hooker, and around it are five panels with Wedgewood figures of plants that in the course of his life he became especially associated with. In the upper corner panels that are to the left and right the plants are an aristolochia, indicating his close association with the African flora, and a nepenthes commemorative of his contribution to the knowledge of insectivorous plants. The lower panel to the left contains a cinchona, which will serve to remind posterity of the important part he took in introducing the medicinal cinchonas of South America to South-Eastern Asia, and thereby rendering a service of immense value to suffering humanity. In the lower panel to the right is a rhododendron, which serves as a reminder of Sir Joseph Hooker's Himalayan travels, and the lower central panel contains a celmesia, which is commemorative of his southern journey with Ross and his work in connection with the New Zealand flora. The portrait is the work of Mr. Frank Bowcher, and is an excellent likeness.

Fruits of Rose Madame Berard.—Taking considerable interest in the diversity of form and colour of the fruits or "heps" of garden roses, we have derived much pleasure from a gathering of fruits of Madame Berard, kindly sent us by that eminent rosarian Mr. Hill Gray, who is wintering at the Azores. The fruits of this strong-growing and beautiful tea-scented variety are oblate and of relatively large size, being nearly one and a-half inches in diameter, and they are brilliant vermilion when fully ripe. Such large and brightly coloured fruits produce a very striking effect when they are borne so freely as is evidently the case with those at the Azores.

The Alpine Flora of Japan is to be made the object of special investigation by the Tokyo College of Science, which is establishing a large botanical garden for the purpose at Nikko, situated in a region of high mountains. The new enterprise, which is, we learn from "Nature," intended as a complement to the two gardens, representing the temperate zone and the tropics respectively, laid out by the College some years ago elsewhere in Japan. The site for the new garden was acquired some four or five years ago, and the necessary adaptations and arrangements are expected to be completed early in the summer of the present year. The buildings erected in the enclosure comprise a laboratory, a residential building for students, experimental greenhouses, etc. The garden is to be divided into eighteen sections for the separate cultivation of all varieties of mountainous flora, ranging from trees and shrubs to ground plants and lichens, and including foreign as well as local growths. Dr. H. Komatsu has been placed in charge of the new station, to which the large collection of alpine species already acquired by the college, but hitherto restricted through lack of accommodation, will be transferred in due course.

Soil in Relation to the Plant.—At the March meeting of the Manchester Literary and Philosophical Society a lecture was given by Mr. A. D. Hall on "The Soil in Relation to the Plant." In his opening remarks, Mr. Hall directed attention to the fact that the plant took but a very small proportion of its substance out of the soil, but that little was indispensable. In particular the plant's growth depended upon the supply of three substances—nitrogen, phosphoric acid, and potash—and the function of a manure was to supply the deficiencies of an ordinary soil in one or more of these substances. It was evident that the substances had to be in solution before they could enter the plant. Compounds of phosphoric acid and potash present in the soil possessed only a very slight solubility, and the soil solution would become saturated to its utmost capacity even though the soil contained much less phosphoric acid and potash than are ever found in cultivated land. The acceptance of this view prevents the difference between good and bad soil being attributed to any difference in the amount of phosphoric acid and potash in the soil; further, additions of these substances could not directly stimulate the nutrition of the plant. This hypothesis had then to face the well-known fact that the yield of crops on particular soils could be greatly increased by the use of certain manures—namely, phosphates. American investigators propounding this theory suggested

that the manure acted by precipitating and putting out of action certain injurious substances excreted by the roots. Attention was paid to the effects of both poor and good supplies of air to the roots, and to the necessity for a good supply. In conclusion, Mr. Hall stated that the theory of the indifference of the plant to the amount of nutrients in the soil was found to be untenable.

A German National Park.—Ten years since Professor Lauterborn, recognising the fact that agricultural and industrial progress in the German Empire had brought about the destruction of certain members of the flora and fauna, proposed that a "Naturschutzpark" should be established for native plants and animals. Subsequent to this proposal being made, the Botanical Society of the Palatinate carefully considered the question, and in 1907 the desirability of establishing a reserve park of a national character was strongly advocated during the anniversary celebrations for Linnæus. For a time the matter did not receive much attention outside botanical and zoological circles, but with perseverance on the part of those who appreciated the importance of a natural reservation the Government has been induced to take action. Acting on the advice of the scientists, it has reserved the country situated between the valleys of Spendel and Wildenstein for the purpose of a "Naturschutzpark." The reserve is to be bounded on all sides by a broad ditch, within boundaries so formed the cutting of wood or any other enterprise is forbidden. Only acknowledged botanists will be allowed to gather the wild flowers, and even such permits will be granted only under the most stringent conditions, since, as is stated in the official minute, it is owing to their scientific zeal that certain species have been practically annihilated in the Haardt and in the Rhine Valley.

Transmission of Plants through Italy.—In consequence of the strong representations made by the Board of Agriculture, the Italian authorities have given permission for the transmission through Italy of parcels containing plants, seeds, and bulbs, provided they are transmitted in sealed receptacles. This condition is fulfilled in the case of parcels for India and the Far East generally, sent in transit through Italy; and there is accordingly no longer any objection to the posting of such parcels for transmission by the overland route to India. This concession is an important one in the case of plants, which suffer by delay, as there is a saving at least a week by sending parcels "via Brindisi."

The Effects of Poisonous Substances on Plants is being investigated at the Rothamsted Experiment Station, and the investigations that have already been made suggest that the subject is one that affords abundant room for research with the probability of obtaining results that will be of considerable value to agriculturists and horticulturists. The investigations are being carried out by Dr. Winifred E. Brenchley, the lady botanist at the station.

BRASSO-CATTLEYA VEITCH THE DELL VARIETY.

Many and beautiful as are the brasso-cattleyas now it is very doubtful whether any exceed in beauty those produced by crossing Brassavola Digbyana with Cattleya Mossiæ. This combination was the first of the series of hybrids derived from B. Digbyana, and first flowered in 1889, at Chelsea, where it was raised for Messrs. James Veitch and Sons by Mr. J. Seden. The Chelsea nursery could hardly contain Mr. Seden on the day that this new hybrid opened its large, bright bloom, and showed, by the wonderful fringing of the large labellum, the possibilities that lay in the use of B. Digbyana as a parent. Many lovely forms of this original brasso-cattleya have been raised, and those which have a white form of C. Mossiæ as parent are among the most exquisite orchids we have. Queen Alexandra and Princess Victoria are varietal forms, and there is a particularly pleasing hybrid with large white flowers. It was derived from B. Digbyana and C. Mossiæ Wagneri. Another grand white form, with a pale yellow area at the base of the wonderfully fringed lip, is The Dell variety, here figured. This was exhibited at Westminster on October 22 last by Mr. Shill, gardener to Baron Bruno Schroder, The Dell, Egham, when it obtained a First Class Certificate. An especially handsome coloured form of B.-c. Veitchi—the Westonbirt variety—belongs to Lieut.-Colonel Sir George Holford; it gained the coveted F.C.C. in 1904.

BRASSO-CATTLEYA VEITCHI THE DELL VARIETY.

Flowers about eight inches across, pure white, with a small, pale yellow area at the base of the fringed lip.

AMONG THE ALPINE FLOWERS.

"The daughters of the year,
One after one, thro' that still garden passed:
Each garlanded with her peculiar flower
Danced into light and died into the shade."
Tennyson.

'Twould be difficult indeed to assert that March had any "peculiar flower" among the many which garland her in the rock garden of to-day. The daffodil may be the flower which "takes the winds of March with beauty," but there are many other blossoms to which we turn with eagerness and joy. We admire the gold and silver of the narcissus, yet we cannot find it in our hearts to say that it is the only flower worthy of our love in these blustering March days. She has all grace and all beauty, yet she cannot monopolise the affections of the lover of all flowers. If the narcissus has her glories and her graces, so, too, have they. The glories may be less overwhelming, but the graces are as alluring as those she presents. The winsome beauty of even the most modest of these flowers appeals to us with an irresistible call, and so we must leave the daffodil to the single-hearted lover of her glorious beauty, and content ourselves by speaking of more retiring nymphs of the garden.

The Green Snowdrop.

Ere the snowdrop passes away again for the year we can hardly let slip the opportunity of saying a word on behalf of the curious, yet pretty, Galanthus virescens. This is a late-flowering snowdrop, which came to this country originally from the Vienna Botanic Gardens, via Baden-Baden, which has found its way into but few gardens. It is very attractive in its own quiet way. Unwilling to assume the virgin attire of its sister flowers, Galanthus virescens has remained almost entirely green. The outer segments are clouded and faintly striped with green, save for their margins, which are white. The inner ones are of a deeper green, just relieved by white at the lower end of the segments. It is impossible to give an adequate idea of the real loveliness of a clump of this green snowdrop. To those who have not seen it the green snowdrop may appear of little charm, but those who know it have a different opinion, and admire the modest attractions of this little Galanthus virescens. It is far from plentiful, but is exceedingly beautiful in the most unassuming way.

Saxifraga gracilis.

From somewhere or other, but from one of several generally good saxifraga sources, I obtained last year a kabschia under the name of Saxifraga gracilis. As with many other saxifrages, one is not at all disposed to accept the name, especially as the great "Index Kewensis" refers S. "gracilis" to three other species, to none of which my plant belongs. It is one, however, which comes very near S. Elizabethæ, and, as at present advised, it resembles it very closely. It is, however, lighter green, has a more lax habit, and has smaller, rather lighter yellow flowers. I have been growing it in a moraine since I received it, and it evidently appreciates its position there, and has thriven remarkably well. Barring the question of the name, I am pleased to have this saxifrage, though it is not specially distinct from several others of the same section.

Crocus tommasinianus.

One wonders why Tommasini's crocus is not more widely cultivated in the rock garden. It is one of the prettiest and most reliable of the smaller species, and is always exceedingly beautiful when it blooms, in the month of March, as a rule, although sometimes as early as February. It is a pleasing little flower, which deserves more notice paid to it, and which, withal, is so cheap that it is within the reach of almost everyone. The colour of the typical plant of the species is lavender, but the plants vary considerably, and varieties known as C. t. atropurpureus and C. t. pallidus are also in the market, the former having purple and the latter lilac blooms. There is a scarce white variety, albus, but this is not in my possession. "Lavender" is hardly a fitting description for the colouring of the typical plant, but "sapphire-lavender" is possibly more descriptive. C. tommasinianus seeds freely, and increases both in this manner and by offsets. It comes from one of the countries which are exciting so much attention at the present time—Dalmatia.

Rhododendron præcox.

Early in the month there opened the lovely peach-coloured blossoms of Rhododendron præcox, one of the loveliest of all the dwarfer shrubs which grace the rock garden. It is not always dwarf, however, as the writer knows a plant which is ten or twelve feet high. It is one, however, which has been in the safe place for very many years, and which has never been kept within bounds by pruning. The writer has a plant some three feet high, and it has been in his gardens for twenty years or so, and has had but little pruning, save as much as would preserve it in shape. Its value in the rock garden is unquestionably high. Its demerits are the facts that it flowers without its leaves, and that it comes so early that the flowers are occasionally caught by frost, and that if this is severe, and the plant uncovered, the flowers may be bereft of their loveliness in a night. But such a lovely plant is worth a little trouble, and a mat laid upon it, but kept off the flowers, when frost threatens, or a handlight raised on stones and put over it under the same conditions will often prove the salvation of the flowers from an untimely end.

Other Flowers.

There are many flowers now in bloom, bulbous plants for the most part, but others as well. There are still some of the old and new varieties of Erica carnea—a galaxy of beauty in themselves; chionodoxas in blue, white, pink, and mauve; scillas, in white, blue, pink, and pale flesh; chionoscillas, the pretty hybrids between the glories of the snow and the squills; primulas, not a few; saxifrages, violas, snowdrops, anemones, muscaris, cyclamens, and a goodly number of other pleasure-giving blossoms which venture to face the gales of a tempestuous March.

S. Arnott.

THE R.H.S. FORTNIGHTLY SHOWS.

At the risk of appearing very dense, I must confess to being unable to discover the purpose of the long letter by "Essex," page 179, of the Gardeners' Magazine.

It seems to me that, having admitted the grievance I complained of really does exist, "Essex" simply wanders away at random until at length, finding himself just about where he started, he makes up his mind to let the matter rest, comforting himself with the assertion that things will get worse instead of better. This may satisfy "Essex," but he must not assume that all the rest of the Fellows of the R.H.S. are content that it should be so. As a matter of fact, there is more than a mild murmuring of discontent, and if "Essex" was at the Hall on March 4 he probably discovered that the discussions on the subject have already become acute, and that "something definite must be done" was the prevailing feeling expressed by Fellows whose one object in paying their subscriptions is to secure the privilege of inspecting the exhibits at the society's shows.

Despite "Essex's" excuses for those who stage mediocre exhibits, and his promises that second attempts would show great improvement, I maintain that the R.H.S. Hall should house only first-class exhibits, and should not be given over to exhibitors who are only trying their hand, or learning what an exhibit should be. Let the beginners gain experience at local shows, or let them pay a few visits to the Hall to see what is required before they venture into what should be the most select and exclusive circle in our horticultural world.

But I do not even agree that it is the beginners who are the greatest offenders. Many an exhibit I have seen at the R.H.S. Hall staged by quite old hands has been neither creditable to the exhibitor or to the Royal Horticultural Society.

As to limiting a group of pot fruit trees, forced shrubs, or bamboos to a ten-foot run of space, I did not say that this should be done; but I do say that a firm or an exhibitor should only occupy such space as can be filled with really choice and attractive products, and, moreover, no one exhibitor should be granted so much space that others are made to suffer as a consequence.

In regard to limiting exhibitors to one show a month, and to separating indoor from outdoor sections, I still consider this is likely to prove the most satisfactory means of removing the trouble which has certainly got to be dealt with in some way. I know there are some of the trade exhibitors who would very readily limit themselves to one exhibit a month if they knew their competitors would do the same, and there are many of the visitors who care only for the hardy plants, and would be quite ready to give up half the meetings to the orchid lovers and perpetual carnation growers, etc. As to the hardship upon the daffodil and dahlia exhibitors, there could doubtless be a workable compromise that would enable these short-season subjects to be specially catered for. At all events, "Essex" must not assume that because he is content to jostle round in a dense crowd, and miss seeing half the things he most desires to see, nothing needs to be done.

Corrigenda.

Carnation Mary Allwood.—Like an old friend, the more one sees of this perpetual carnation, the greater the appreciation. The perfume is good and lasting, and the colour is a shade between the varieties Mrs. Clode and Leander. It gives a colour which has been wanting in perpetual carnations, and, apart from the question of colour, it has fine form and build, and therefore possesses most of the essentials in a thoroughly good carnation. I have been particularly impressed with its lasting qualities in a cut state, and have had blooms remain in good condition for more than a fortnight, these retaining their colour and fragrance to the last in an ordinary sitting-room.—Paul T. Moore.

STRELITZIA REGINÆ.

No doubt, owing to the fact that in most botanical gardens this plant is generally cultivated in a tropical temperature, it is rarely seen in private gardens, where the stove houses have usually to be occupied by plants which are more suitable for either filling plant-vases in the dwelling-house, or for supplying cut blooms. But anyone who possesses a warm greenhouse may well grow this uncommon and handsome plant. Indeed, when so treated, it is generally more floriferous than when grown as a tropical subject, because the greater amount of heat induces the production of richer foliage.

The best soil suited to the Bird of Paradise flower, or the Bird's Tongue flower, as it is variously styled, is two parts of roughly-broken fibrous loam and one of peat, with the addition of plenty of broken charcoal and coarse sand. As abundance of water is required during the growing season, the pots should be well drained, and the soil pressed only moderately firm. During the flowering season, and throughout the resting period, very little water is required, as Nature has given the plants thick fleshy leaves and cellular stalks, which enable it to withstand an annual period of drought. Yet at the same time it is not wise to keep the plants so dry that the foliage shrivels.

Few greenhouse plants can equal in gorgeousness the flowers of Strelitzia Reginæ; the stout spikes, which rise above the broad shining leaves, bear flowers of rich bluish-purple and orange, escaping from a farina-clad flower scape. Where sufficient headroom cannot be given to this species, S. humilis, which Nicholson's "Dictionary of Gardening" quotes as being "a reduced copy" of the former, might be grown. In larger houses, S. Augusta, which usually flowers a month earlier than S. Reginæ, is also well worthy of culture. Even when not flowering these species are decidedly ornamental. Cecil Aubrey.

ASTERS FOR BEDDING.

In late summer and autumn the asters add very considerably to the garden's charm, provided they are well grown and planted boldly in suitable positions. They never look better than when filling large beds, and the accompanying illustration shows such a bed in the Torwood Gardens, at Torquay. Asters afford ample room for the exercise of a variety of tastes because the florists have perfected a number of widely distinct strains. For those who like the more compact plants and rather formal flowers the Victoria, Bouquet, and French strains appeal strongly, while the chrysanthemum-flowered sorts are quite dwarf, but give a little more freedom of form.

Latterly, however, the more elegant strains have found great favour both for garden decoration and for cutting. The Comet, Ostrich Plume, and Ray asters, and the newer single varieties of the Southcote Beauty type, deserve all the popularity they enjoy, because of their free and graceful form and habit, and the considerable range of colouring they present. The rose and pink shades of the Ostrich Plumes, the white and peach-pink forms of the exquisite Comet strain, the white and primrose Ray asters, and the white and rich pink shades found in the Southcote Beauty, or plumed, single varieties, all excite admiration. The single sorts grow up to two and a-half feet high, and are, therefore, splendid for large beds and groups. In a private garden these must be grown in reserve quarters as well if a bed is planted because the ladies of the household will most certainly want large numbers of their elegant, golden-centred blooms, on long stems, for home decoration.

Thick sowing and failure to transplant the seedlings early are the chief causes of failure among asters, and yet such failures could so easily be avoided. Raised in the gentle heat of a warm greenhouse, pricked out into boxes containing fairly rich soil, and composed largely of loam, leaf-mould, grit, and again transplanted in a frame over a spent hotbed before they become drawn or starved, asters will grow well, and make a fine root system by planting-out time. While in the frame they can be adequately cared for in the matter of air and water, and if placed about six inches apart either way they make excellent material for beds or borders. When only once transplanted, and allowed to grow thickly in boxes, asters are seldom a success, and even though they flower they can in no way compare with plants treated in kindlier fashion, and allowed more room to develop. Two dozen first-rate asters are worth far more than fifty half-starved ones.

A FINE BED OF SINGLE ASTERS IN THE TORWOOD GARDENS, TORQUAY.

Vegetable Marrows.—Where conveniences exist for obtaining an early crop, sow the seeds singly in small pots, and place in a temperature of about 60 deg. As growth proceeds shift into 48-sized pots, and when well established, plant out on a mild hotbed in a pit or frame. If an early crop of potatoes is lifted from a pit the marrows may be planted in its place. If there is a spare space in an intermediate house, plants may be put in boxes and trained up the trellis. Moore's Cream and Pen-y-byd are suitable varieties for early crops, being productive and of high quality.—W. Messenger.

PERPETUAL-FLOWERING CARNATION NOVELTIES OF 1912.

New varieties of perpetual-flowering carnations are essential because the old ones deteriorate in time, so must be replaced and when good novelties are disseminated all are benefited. Never in the history of the flower have so many good varieties been sent out in one year as during last season. The International Show must account for this supreme effort, and certainly the position of the flower has been greatly strengthened.

It is impossible to say definitely which is the best novelty of the year, because various varieties have different uses, but the following will be the most popular.

Triumph, from the cut flower standpoint, is the crimson variety of to-day, producing two flowers to every one of Carola. However, those who still prefer fine quality will cling to the latter variety, yet I predict a great future for Triumph.

Empire Day is a variety which practically everyone will grow soon; it was never shown or advertised so much as its merits warrant. The colour is a clear shade of pale salmon-pink; flowers are of good size, and the habit of growth is always robust and healthy, with strong stem and calyx. This variety I consider the best pale salmon-pink, and one everybody should cultivate.

Rosette is deep bright cerise, a shade long sought after, and, compared with other varieties of similar shades, Rosette is much purer and brighter in colour, while in habit, stem, and calyx little more can be desired. Unfortunately the flowers lack scent, but this is practically its only shortcoming.

Wivelsfield Wonder is white, daintily flaked rose-pink. Flowers, large and full, with good scent. The growth of this variety is exceptionally strong and healthy, and it resembles Enchantress in formation of flower and growth, but is more robust.

Benora, white, flaked red, has finely, well-formed flowers of good size, and a healthy growth, which is quick, but does not make a large bushy plant. The flowers of this variety are totally distinct from those of Wivelsfield Wonder, and which is the most beautiful of the two is a matter of taste.

Lady Northcliff is salmon-pink, similar in colour to that popular old variety, Mrs. H. Burnett, but it is more free in flowering. However, the blooms are not so large as those of Empire Day, but perhaps it is a better producer.

Mandarin, yellow, heavily flaked rosy-pink, is, perhaps, the best yellow fancy variety yet produced; it has excellently-built flowers and free healthy growth.

La Rayonnante, large, maize-yellow, the flowers measuring four inches and over, is very strong and healthy, with ideal stem. The calyx splits, and it is not so free flowering as same varieties, but is undoubtedly the best clear yellow.

Sunstar, bright yellow, with pale pink and white markings, has flowers of large size, with good stem and calyx; the growth is free and robust. Certainly an excellent variety.

Lady Meyer, flesh-pink, several shades deeper than Enchantress, is a variety which promises to supersede our old favourite, as the calyx, stem, and growth are much stronger, and not affected so much by dull weather; it had the distinction of giving the premier vase at the recent show.

Baroness M. de Brenien, salmon-pink, has very large, massive flowers. The growth is particularly strong. This should prove an excellent exhibition variety, and its slowness in flowering is compensated by the fine quality of the blooms.

Fairmount, heliotrope, with a French grey finish, has flowers that are large and well built; the growth is strong and healthy. Fairmount should supersede that popular old variety Mikado.

Geisha, heliotrope, with a suffusion of salmon at the base of the petal, has wonderful long, erect stems, and robust growth.

Coronation, silvery-pink, gives medium-sized flowers, and is of free growth; unfortunately the flowers are affected by the sun, and often assume a magenta shade.

Duchess of Devonshire, deep crimson, with flowers of beautiful form, is, unfortunately, not quite so free-flowering as some of the varieties.

Cinnabar gives a distinct shade of a rich red-brown colouring; the flowers are small, but beautifully perfumed; a very healthy grower.

Wodenethe has large, full white flowers, and strong healthy growth; it is not so free flowering as White Wonder, but should be popular.

St. Nicholas, scarlet, is bright, but the flowers are rather thin and small. Scarlet Glow is still, I think, the best scarlet.

Elektra, orange, edged pinkish apricot, is a free and healthy grower. The flowers are not large, but they are greatly admired.

Hayward's Heath.

MISTAKES WITH ANNUALS.

The raising of some seeds is such a simple process that it is one of the first things the child learns to do in the garden, though it is true it is done in a rule-of-thumb fashion, and it is not always certain that he will get even moderate results with those of the easiest culture. Some amateurs do not advance much beyond this stage in later life, for they do not realise that annuals, as a class, are not easy things to grow well, and that unless they are really well grown they are little better than weeds, in fact not so good as some weeds.

Sowing Too Thickly.

The first and most general mistake in their cultivation is that of thick sowing, and that is one which even the most experienced fall into sometimes. We are so anxious to have the ground well covered, and that without waiting very long. When seeds are sown thickly irremediable injury is done to the seedlings however soon they are thinned, as they become leggy directly they are up, and then they are always weak at the base, and soon fall over. In thinning a bed of seedlings all groups or clumps of seedlings should be pulled up completely, selecting those to remain which have a clear space round them to start with. Thinning should be done gradually, leaving the best plants at each thinning and not hesitating to pull up plants because they are large and strong if it is seen that they will unduly crowd others. Few people leave Shirley poppies, for instance, eight or ten inches apart, and yet they will pay for this distance, and even more, under very good cultivation.

Poor Cultivation.

Another mistake almost as common as the preceding, and quite as harmful in its results, is poor cultivation of the soil. Let anyone prove this for himself by taking up one plant out of well-cultivated soil and another from soil which is badly cultivated, and noting the difference in the root systems. The finer the tilth of the soil the greater will be the number of roots, and as each little rootlet contributes to the well-being of the plant, the stronger and better the latter will be. The greater the depth of cultivated soil, too, the greater the range for collecting the food supply, and the longer the plant can withstand drought. The enrichment of the soil is included in the term good cultivation, but this part of it is not necessary for all annuals, and this should always be borne in mind. Tropæolums, for instance, will run to leaf if the soil is rich; salpiglossis will die away unexpectedly and mysteriously if the soil is damp as well as rich.

Late Sowing.

Another mistake with hardy annuals is late sowing. Every countryman knows the poor results often following the late sowing of spring corn, the warm or even hot weather of late May or early June coming before the root systems are sufficiently extensive to maintain the rapidly increasing size of the plants, with the result that they are forced into flower too early. On any but the heaviest and wettest soils most annuals may safely be sown the last week in February, or as soon after as weather conditions permit, and many, especially in light soils, will do better if sown from July to September, according to the sort, when they will make fine plants and keep up a longer display, though they will come on so early, in many cases, that we shall need to have successional plants ready by the end of July.

It needs a considerable knowledge of annuals to avoid using them in the wrong way. Their character is very diversified, and, if we are going to use them all in similar fashion, we shall make great mistakes in the garden. Love-in-a-mist, malopes, and godetias, however beautiful in their different ways, will make ugly gaps in the beds and borders early in August. These cannot be used in such positions without having material in readiness to put in their places as soon as they begin to fade. There are some annuals, in fact many, which are admirably adapted for use as bedding plants, and only those should be used for the purpose, but in raising them it should be borne in mind that if they are not raised until April it will be the middle of July, or even later, in some cases, before they are producing any effect, by which time the best part of the summer is over. The middle or end of February, or, at latest, early March, is not too early to sow most of the bedding annuals, and we need not be afraid of having them in flower too early, as they will last in flower throughout the summer.

Alger Petts.

Browallia speciosa major.—This makes a charming greenhouse plant, and is very easily cultivated. Sow the seeds now in pans of light sandy soil, and place in heat till the seedlings are through. A shift into small 60-sized pots when large enough, and later into 48's, is all they require. They must be stopped once or twice to encourage a branching habit. Their bright blue flowers are very effective during late summer and autumn.—E. Harriss.

ROSE ELLEN POULSEN.

Conspicuous in several of the beautiful collections of roses exhibited by Messrs. William Paul and Son at the meetings of the Royal Horticultural Society held during the summer and autumn of last year, was the charming variety Ellen Poulsen, of which an illustration is given here. This variety belongs to the dwarf polyantha section, was introduced in 1911-12, and during the past year it proved so satisfactory as to be regarded as a valuable addition to the dwarf bedding roses. Under good cultivation, such as it would receive in the Waltham Cross Nurseries, it attains a height ranging between eighteen and twenty-four inches, and produces freely and continuously its large clusters of bright cherry-rose flowers. The form of the flowers and their arrangement in the truss, which was cut from one of Messrs. W. Paul and Son's plants, is so admirably depicted that further description is unnecessary. It must, however, be said that the flowers are delightfully fragrant, and that the petals have a cream-coloured base. The foliage is dark green, and described as mildew-proof; and the variety is of much value for forcing. Where the distinctive charms of the dwarf polyantha roses are appreciated Ellen Poulsen should be included amongst the newer roses selected for planting this spring.

SMOOTH CAYENNE AND CHARLOTTE ROTHSCHILD PINEAPPLES.

In these days, when British-grown pine-apples are seldom asked for, and consequently gardeners generally need take but little interest in them, from a cultural or any other point of view, I ought perhaps to apologise for trespassing upon space in alluding to them. Having, however, been asked particulars respecting their culture, and the origin of the above-named varieties, and being unable from the means at command to enlighten my correspondent about the latter part of his enquiry, may I ask if any reader of this note will assist me?

The Smooth Cayenne has, I am aware, been considerably longer under cultivation in this country than has Charlotte Rothschild, though it is not mentioned in the first editions of either "Johnson's Cottage Garden" or M'Intosh's "Practical Gardener," nor is it referred to by Mr. Donald Munro in his "Report upon Varieties of the Pine-apple" published in the first volume of the "Transactions of the Royal Horticultural Society" (1835), in which 52 varieties are described. No doubt it would have been included in this lucid description of varieties had it been under cultivation at the date of publication, for it is one of the very best of pine-apples, especially for affording a supply of ripe fruits, of excellent flavour and handsome appearance, during the winter and early spring months. It is likewise the most valued for colonial cultivation and export, and the fine condition in which it is thus produced can be frequently observed at the establishments of leading fruiterers.

The late Mr. D. Thompson, in the "Culture of the Pine-apple," speaks of this variety as weighing 11b. for every pip in depth, and this, as we have many times proved, is not an excessive estimation. At one time an inferior variety of Smooth Cayenne was common in collections, and I found it here when taking charge of these gardens.

I recollect first seeing plants of the variety Charlotte Rothschild in 1870, and they were grown at Duporth, in Cornwall, by the late Mr. Bacon. At the same date, at Tregrehan, in the same county, pine-apples were grandly managed by Mr. Woolcock. I well remember Mr. Bacon, when speaking of Charlotte Rothschild, referred to it as a new variety, and said his plants were the first of it he had fruited, and I believe I am right in saying he obtained the suckers from Mr. Barnes, who was then gardener at Bicton, and distinguished as a cultivator of pines. From these recollections it may be supposed it had at that date been but recently introduced.

Relative to pine-apples, it may be remarked that I am informed by two former assistants, respectively manager and assistant manager of tea plantations in Cachar, that these fruits are quite easily brought to perfection there in open quarters, the flavour being excellent, and this I see is confirmed by Thomas Carson, who writes in a chapter on Tea Planting, in "Ranching, Sports, and Travel": "At Scottpore, in Cachar, I think I grew as fine pine-apples and bananas as were produced anywhere. The pine-apple contains no fibre. You can cut the top off and sup the delicious mushy contents with a spoon."

The Hendre Gardens. THOS. COOMBER.

ROSE ELLEN POULSEN.
A dwarf polyantha variety, the flowers bright cherry-rose.

GLORIOSAS.

Having been rested, the tubers of gloriosas may now be taken from their pots and repotted, placing several in 10in. or 12in. pots. When finished, the tubers should be covered by an inch or so of the compost, which may consist of fibrous loam, peat, and leaf-mould in equal parts, with the addition of a little well-decomposed manure and some sand. If the compost is in good condition very little water will be required until the growths appear, when moist heat will be necessary. G. superba and G. Planti (or virescens) are both useful for covering stove rafters and for affording cut flowers in late summer and autumn.—H. PRIME, Hatfield House Gardens.

NOTES FROM SCOTLAND.

Early Potato Planting.

The weather in the latter part of February was all that could well be desired for planting the sprouted tubers that form the advance guard of this important crop. Not only has rainfall been almost absent, thus rendering the light, sandy tracts of soil bordering the sea for miles along the western coasts of the counties of Ayr and Wigtown in splendid working order, but the general non-prevalence of wind has greatly aided in the task of applying artificial manures and the efficient preparation of the ground.

Morning frosts have somewhat retarded field operations occasionally, until the day was well advanced, but in general, in connection with this work, much requires doing under cover at the homestead as well as in the open fields. To all appearances the present season's crops will equal, if not surpass in area any that have gone before, while the tubers, having kept well in store and sprouted strongly, afford grounds of hope for another prosperous and bountiful year.

Roses and the Winter.

Not for many years—certainly never since the Hybrid Tea and Rambler sections came into such prominence, and their culture become so universal as at present—has such destruction among the plants been experienced as is the case now made manifest by the numerous dark-coloured stems without a sign of returning sap activity. The damage now apparent has been partly suspected for some time past, but was tempered with the hope that with advancing spring a fair proportion of the shoots would resume their accustomed vitality and a fair amount of vigour. In many cases, such hopes are now dispelled, for it becomes daily more evident that many plants which have successfully withstood the rigours of previous winters are killed to the root, and that, where budded, the stock may grow, but the scion has passed beyond revival.

This, too, applies not specially to one establishment or district, but to the greater portion of the southernmost extent of Scotland. The winter now closing, though having been a most trying one for all connected with the soil, was more remarkable for rainfall, snow storms, and boisterous winds, than for very severe frost.

The harm done to roses undoubtedly occurred in November, when on two successive nights from twenty to thirty degrees of frost were registered, varying, of course, in intensity according to the situation and the district. At that time the plants were in full foliage and the stems highly charged with sap, and thus ill-prepared to endure the sudden change. Shrubs of several kinds, as myrtles, bays, and laurestinus, and those of deciduous character, as buddleias, magnolias, and tree lupins, are much damaged.

Exhibitions and Improvement Societies.

The first-named, for the coming season, appear to be in the ascendant. The thriving town of Dumfries, so conveniently situated and so well connected by way of railway communication from all parts, seems to have headed the forward movement. Early in January a few ardent horticulturists met and had under discussion the advisability of instituting a rose and sweet pea society. This culminated in a schedule of rules and prizes, with the provision that an exhibition be held at or near Dumfries about the third week in July, when both flowers are usually at their best in northern gardens. Since then another society, more general and further reaching in its scope, has in turn been formulated with powers to arrange for and to hold an exhibition about a month later than the former.

Dumfries claims to be among the first, if not the pioneer, centre in the kingdom in which a purely horticultural society was established, but, strange to say, with its historic past and all its present-day advantages as to population, industrial activity, and convenience of access, coupled with the onward and upward march of horticulture in general, it has, in recent years, been unable to hold its own financially or in the extent and importance of its annual exhibitions. And this in spite of the fact that different bodies of men, well versed in horticulture and possessing good business acumen, have from time to time served upon its committee.

We read that the man who makes two blades of grass grow where but one grew before is a benefactor to the race. In the case under notice two committees of men will endeavour to make two shows or societies thrive where one failed before, and, as the material at their disposal is not widely different to that available in the past, the working arrangements and final consummation will doubtless be watched with considerable interest by many engaged in the gentle art of horticulture.

Labour and Wages.

Amid the general unrest, and appeals of the employed for better conditions and higher remuneration for labour among classes far and away better requited in this respect than are gardeners in general, it is surprising that the latter, beyond the customary grumble, bear so patiently the seeming injustice of their lot. As illustrating the reasonableness and goodwill existing between the Edinburgh masters and men engaged in the jobbing trade of the city, as culled from newspaper reports, it may be stated that at an arranged meeting, at which both parties were about equally represented, the most harmonious feelings seem to have prevailed, and it was resolved that higher charges should be made for work performed, the additional charge being placed almost entirely to the credit and benefit of the workmen, of whom the employers or their representatives spoke in the highest terms as to intelligence and industry. Could something similar be carried out in private gardening, whereby employer and employee were brought into closer contact and conference, it might in very many cases lead to an adjustment of real grievances which are now borne in sullen silence.

Things of this sort may in course of time rectify themselves unaided, as any gardener having to deal with several assistants is well aware of the difficulty of obtaining suitable and trustworthy men; or, if obtained, to retain their services at the rate of wages that sufficed in years gone by. This has already resulted in a considerable betterment in the conditions of housing, as well as in the remuneration given to young men.

James Day.

SOME USEFUL STONECROPS.

The charming group of Sedum Alberti shown in the accompanying illustration will give a good idea of the usefulness of many members of this succulent-leaved family. In too many gardens the few sedums that are grown may be generally found relegated to odd corners and out of the way places, where they fail to do themselves justice. They are, however, very good-natured plants, and even under such conditions make themselves attractive, and show to what useful purposes they may be put. For dry banks and rocky ledges in the rock garden the dwarf, carpeting species are almost indispensable, covering the ground during the whole of the year with foliage, and producing sheets of beautiful flowers in the summer months. They will grow on places where it would be difficult to get other plants to thrive, and thus are all the more valuable.

Besides carpets of crimson and purple, green and white, and golden-yellow, as well as many other shades of colour, there are taller-growing species of elegant and striking habit, which form bushy specimens, like S. spectabile, with stout stems and large fleshy leaves. These, in autumn, are topped with large heads of rich purple flowers that are very handsome. The following notes, however, are confined to those dwarf-growing species that may be relied upon to quickly form spreading carpets of pleasing foliage of different shades of green, and produce sheets of brilliant flowers in summer and autumn. Some of the more beautiful ones, like S. pulchellum, must necessarily be omitted from this list, as it does not prove hardy in many places, but its rose-coloured flowers are very handsome.

The stonecrops are all of easy culture, flourishing in borders that are sufficiently well drained, crevices of old walls, dry stony banks, and sunny pockets in the rock garden. There is no difficulty in the matter of propagation, as even the leaves of some species, like S. dasyphyllum and others, rubbed off and scattered about, will soon form buds, succeeded by plants, in a short time. Seeds are also produced freely by some species.

S. acre, the Wall Pepper, or Biting Stonecrop, is a native plant which is practically covered in early summer with sheets of bright yellow flowers. Owing to its spreading so freely it is apt to become a nuisance where rarer plants are grown, so care must be exercised in placing it. It is extremely useful for borderings or the tops of old walls. A very pretty form is S. acre aureum, every growing point of which, in spring, is golden-yellow.

S. Alberti, here illustrated, forms a carpet of interlacing stems and short terete leaves, covered in summer with panicles of white flowers. It is only about three inches high, grown on dry, open places, but in the more shady places it is liable to get drawn. An exceedingly useful carpeting plant, S. Alberti is a native of Turkestan, its introduction to cultivation being due to Dr. Regel, of St. Petersburg. It is closely allied to S. album, commonly known as the Worm Grass, another native of this country. The creeping growths are clothed with evergreen, short leaves, and in summer are covered with clouds of comparatively large white flowers on pink stems. For a sunny bank there is no more effective plant when in flower, while in winter and other parts of the year it may be used to provide a clothing for dry and arid positions.

S. brevifolium, the Mealy Stonecrop, is a beautiful little evergreen plant, which has

been described as looking like a mass of silvery, rose-tinted globules of meal, so rounded and covered with powder are the leaves. It will thrive on a dry, sunny ledge, but is one of the least hardy of those included here. The flowers are a pinky-white, but the chief attraction lies in the pretty foliage.

S. Ewersi is a very ornamental Himalayan plant, with semi-trailing stems a few inches long, glaucous, rounded leaves, and clusters of purplish flowers. These are produced from July to October, and render this a valuable plant for the rock garden where flowers are beginning to get scarce at this time of the year. S. E. turkestanicum is a variety with rosy-purple flowers.

For rapidly covering a given space there is no other sedum, except S. spurium, to compete with S. oppositifolium, which comes from the Caucasus. It is evergreen, a perfect curtain, draping the wall with evergreen foliage, replaced in summer by the crimson flowers. Like S. oppositifolium it is a native of the Caucasus, and very similar to it in habit.

S. ternata is a glabrous evergreen plant with spathulate leaves in whorls of three up the stem, and crowded into rosettes at the top. The masses of white flowers in loose cymes are produced in May and June, and last in perfection for a long period. It is a native of Western North America, and usually found growing on the rocky banks of streams, but although a moisture-loving plant, it succeeds well in open, sunny situations, planted in sandy loam.

There are many other beautiful plants contained in this genus besides those above-mentioned. They are of various habit, from the tall-growing S. maximum, with large fleshy leaves and broad corymbs

CRATÆGUS PINNATIFIDA MAJOR.

From its foliage alone this tree may be readily detected in a collection of thorns, for, though shaped somewhat like the leaves of our common whitethorn or hawthorn, they are of large size, thick texture, and deep green colour. The blades of the larger leaves are up to four and a-half inches in length, and four inches wide, with stalks a couple of inches long. Neither is it in leafage alone where special size is noticeable, for the white flowers are larger than those of most species, while the showy red fruits are almost an inch long, and the same in diameter. They are very fleshy, comparing them with those of C. tenacetifolia in that respect. Added to this, the tree is of vigorous habit, with large, rounded, distinct buds, and few spines. It is certainly one of the most

SEDUM ALBERTI.

An attractive species with white flowers on pink stems.

with long trailing stems, and bright green flat leaves. In shady places it grows very fast, but does not there produce its good-sized white flowers so freely as when planted in a more open, sunny place. Like the preceding, it is a late summer and early autumn-flowering plant.

S. rupestre and S. reflexum are two native species of similar habit, with procumbent trailing stems, closely set with narrow leaves of glaucous green. S. rupestre bears masses of clear yellow flowers during the summer. It is very variable in habit, and there are several different forms of it in cultivation. All are exceedingly useful carpeting plants.

The rich crimson heads of flowers borne by S. spurium are very attractive. It is most effective when planted on the top of a retaining wall in a sunny position. The long trailing stems grow down, and form

of greenish-white flowers, to the diminutive S. brevifolium. Those of the Aizoon section, including S. kamtschaticum and S. Maximowiczi, with erect stems and, mostly, yellow flowers, are very useful border plants. One of the most distinct is S. spathulifolium, from Western North America, which has glaucous leaves in pretty rosettes, and pretty citron-yellow flowers. It must be planted in a very dry, well-drained position. W. Irving.

Eurya latifolia variegata.—This camellia-like greenhouse shrub is remarkable for the manner in which the shining leaves are variegated. Of a green ground they are marked with creamy-yellow and grey in varying amounts, and very differently arranged. The young leaves are suffused with pink. It forms a very pretty object in the greenhouse.—T.

distinct of the many kinds, but it is doubtful whether it is so generally useful and ornamental as some of the American sorts, and is certainly less decorative than C. coccinea, C. mollis, and others of that class. A native of China, it has long been known in our gardens. W. D.

Grasses in Pots.—Some of the annual grasses form very pleasing subjects for greenhouse decoration, if sown in five or six-inch pots, and allowed to come on gradually, giving them plenty of light and air. Particularly suited for the purpose are some of the Agrostis, such as A. pulchella and A. nebulosa; Brizas of sorts, especially Briza maxima, Hordeum jubatum, Bromus brizæformis, Lagurus ovatus, and others. They will serve the useful purpose of lightening up a group of flowering subjects.—K.

HYDRANGEAS: NEW AND OLD.

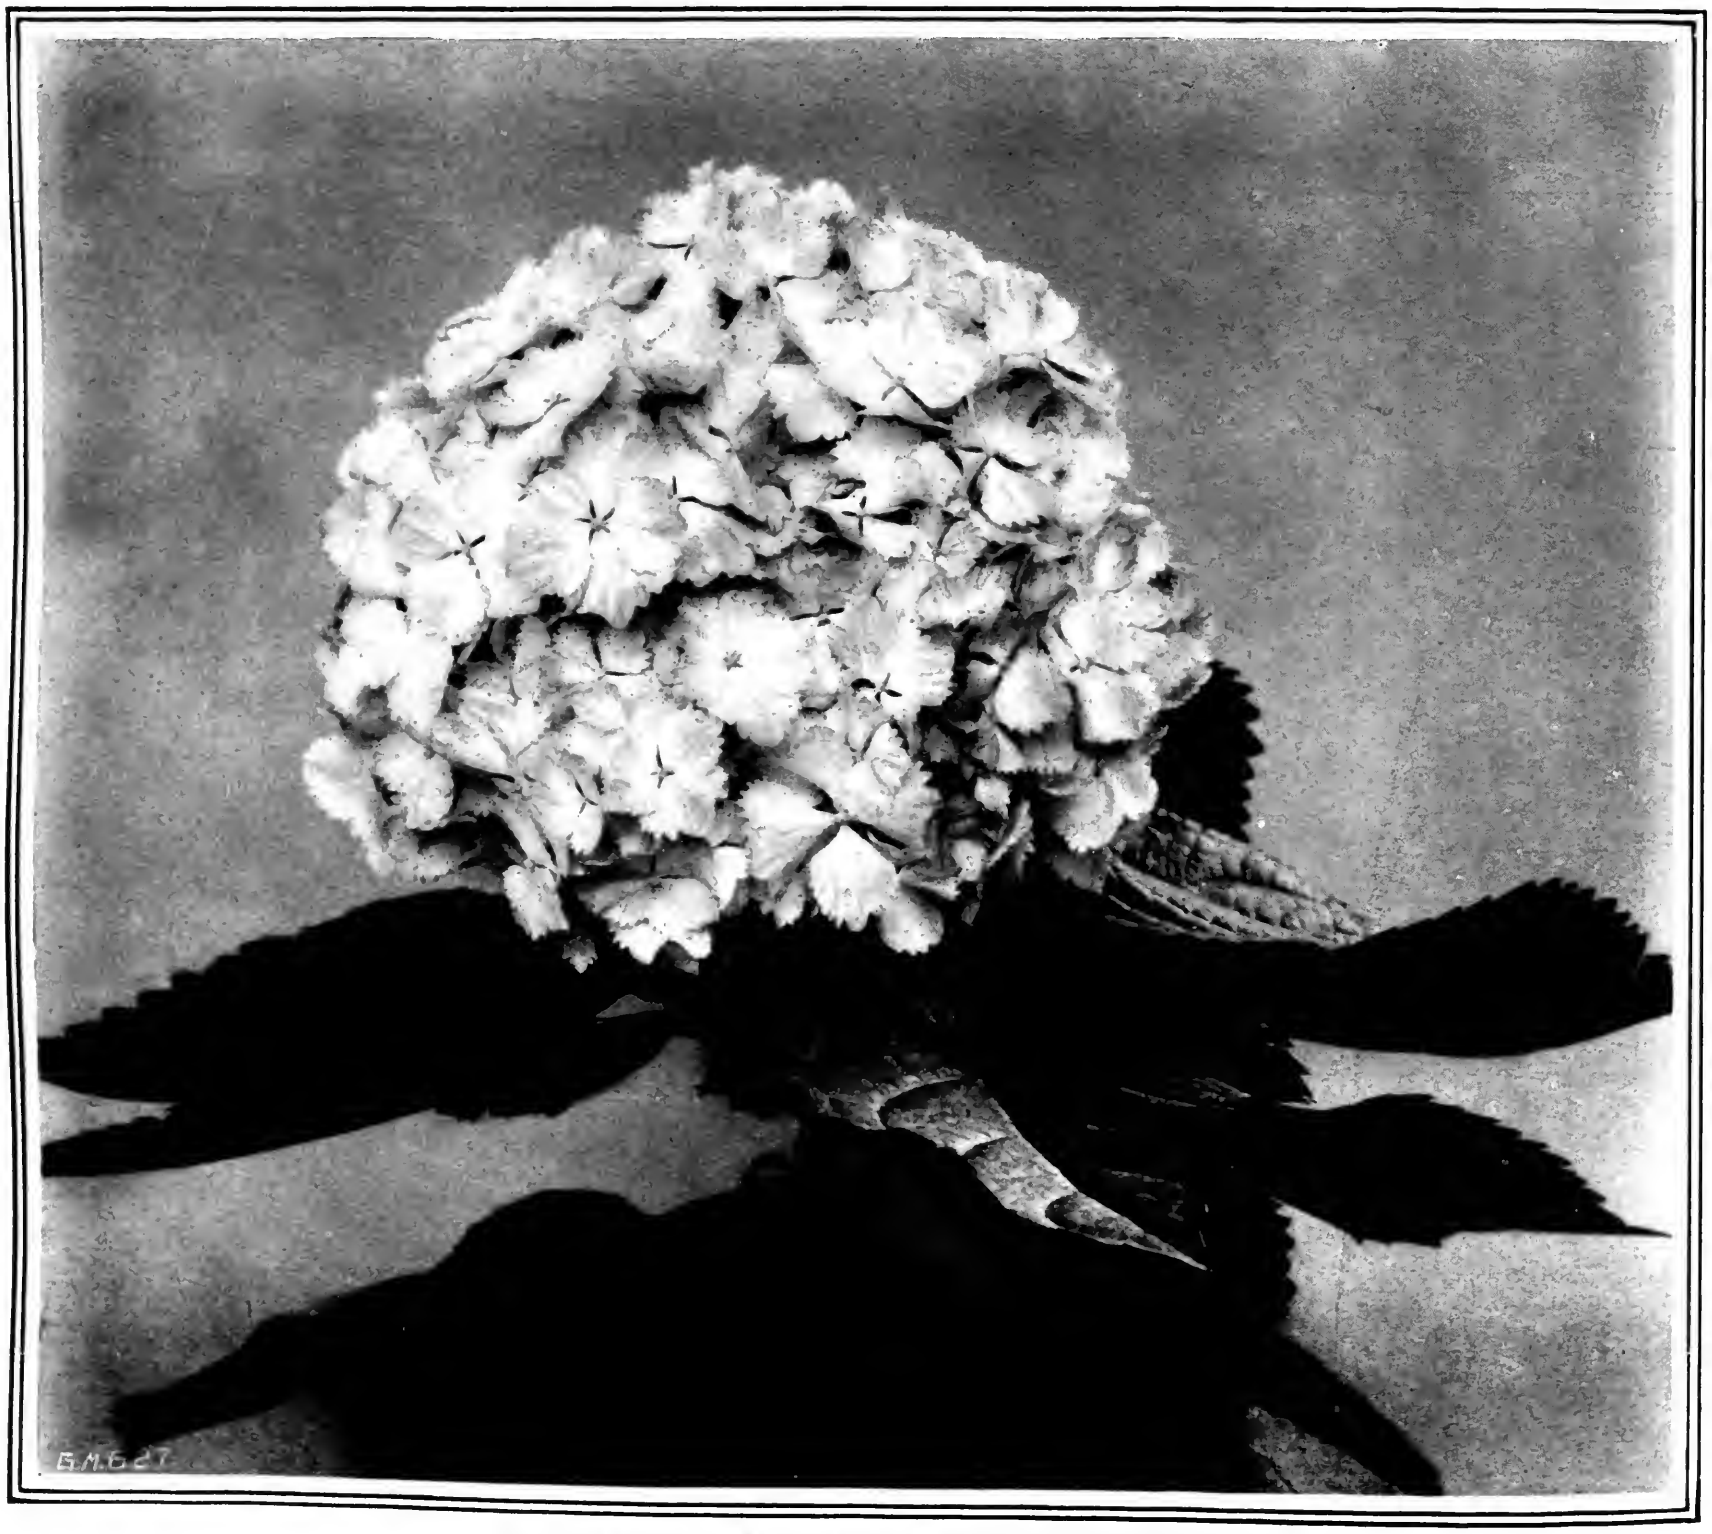
The genus hydrangea is a fairly extensive one that, in a state of Nature, occurs principally in North America and in North-Eastern Asia, including Japan. Far and away the most popular of all is Hydrangea Hortensia, which forms such a feature of many gardens in the south and west of this country, and in other places, especially in proximity to the sea, for it seems to favour a near association with "the briny." A fine specimen in a Torquay garden is herewith illustrated. The neighbourhood of the sea is, however, by no means essential to its well doing, as delightful specimens may be met with in the home counties where conditions are favourable; and grown in pots for decorative purposes, it figures largely in Covent Garden Market over a considerable period of the year. In addition to this, specimen plants grown in large pots or tubs are exceedingly valuable for standing on terraces or in similar positions during the summer months.

The use of Hydrangea Hortensia itself as a decorative subject, and its ornamental features out of doors where the weather is not too severe, have, however, been at different times dealt with in the pages of the Gardeners' Magazine, notably in the issue for August 10, 1912. Such being the case, I need say nothing further on that point, but confine myself to mentioning a few of the most distinct of the recognised varieties, and the numerous garden forms that have within the last few years been raised on the Continent, and are now in some cases largely grown.

Prominent among the varieties that have been introduced from Japan, and of which some have before now been looked upon as true species, is H. H. Lindleyi, one of the most distinct of all, differing as it does in many ways from the typical kind. The shoots are far more slender, and the leaves and flower clusters much smaller. The flowers are produced from the axillary as well as terminal buds, so that even should the point of the shoot be injured by frost there will be, as a rule, a fair display. The major portion of the blossoms are small, fertile ones of a bluish colour, but there are enough of the large sterile ones to make a goodly show. These last are of a rose colour, becoming, in some cases, almost crimson with age.

In H. H. Mariesi, the main feature is the immense size that the sterile blooms attain. They are of a deep pink colour, and are limited to a scattered few around the outside of the flower cluster. The variety Veitchi is a counterpart of this except that the sterile blooms are white. H. H. nigra, also known as cyanoclada and mandchurica, derives its name from the bark of the young shoots, being of a shining black tint, very different from the ordinary forms. The flowers, borne in massive heads, are of a bright rose colour. It has long been a favourite for pot culture.

H. H. Otaksa is one of the best of the Hortensia class; that is to say, it represents a very good form of the type, but does not differ in any marked manner therefrom. H. H. rosea is somewhat after the manner of Lindleyi, mentioned above, in habit, but the flowers are all, or nearly all, sterile and of a rich, bright rose colour. H. H. stellata, of rather weak growth, is remarkable from the fact that the sterile flowers are more or less double, which feature renders it quite distinct from any of the others. It forms a very pretty greenhouse plant. H. H. Thomas Hogg, a variety introduced from Japan by way of the United States many years ago, was, until Madame Emile Mouillière was sent here from the Continent a few years ago, grown almost to the exclusion



HYDRANGEA MADAME RENEE GAILLARD.

A new and distinct variety, bearing large heads of fimbricated flowers which are white tinted with green. It was well shown by Messrs. T. S. Ware, Lim., Feltham, at the R.H.S. Meeting on February 4, the plant illustrated having a flower-head about twelve inches in diameter.

of any other white-flowered kind, and it is still very popular for market culture.

Within the last few years two raisers, namely, M. Moullière, of Vendome, and M. Lemoine, of Nancy, have devoted a good deal of attention to the raising of new hydrangeas, and have put a great number of varieties into commerce. One of the first—Madame Emile Moullière, was given an Award of Merit by the Royal Horticultural Society on May 3, 1910. This variety is of good, sturdy, growth with massive heads of white flowers. It has proved to be an ideal kind for cultivation as dwarf plants in comparatively small pots, each carrying one large head of blossoms. A second variety—Ornament—received a similar award at the same time. The flowers of this are also white, a marked feature being the deeply serrated segments of the sterile blossoms.

President Fallieres, huge heads of bright pink flowers; and Ronsard, a light flower with a markedly distinct deep pink centre, much serrated at the edges, a very striking variety.

Of species other than Hydrangea Hortensia by far the most popular in gardens, both as an outdoor shrub and for growing in pots, is H. paniculata, or rather its variety grandiflora. This, which flowers naturally in the open ground in August, is by some of the growers for Covent Garden Market forced into bloom much earlier. It produces large pyramidal heads of creamy-white flowers, which, when fully exposed to the sun, acquire a reddish tinge. Though this variety is so well known, the typical H. paniculata is comparatively scarce. It differs from grandiflora in being more vigorous in growth, with darker green leaves, and especially in the flower clusters, which consist mainly of small fertile blossoms, the large sterile ones being scattered over the entire cluster. Opinions, of course, vary, but personally I prefer the type, as an outdoor shrub, to its better-known variety.

Mention must be made of Hydrangea arborescens, a North American species, which forms a vigorous bush, clothed with large heart-shaped, deep green leaves. The flowers are not particularly showy. This kind might well be passed over, but for its variety, grandiflora alba, which is of comparatively recent introduction. It originated in the United States as a sport, the main point of difference being that the flower clusters are composed of large, sterile, pure white blooms, suggesting those of the Guelder rose. It is undoubtedly of great promise.

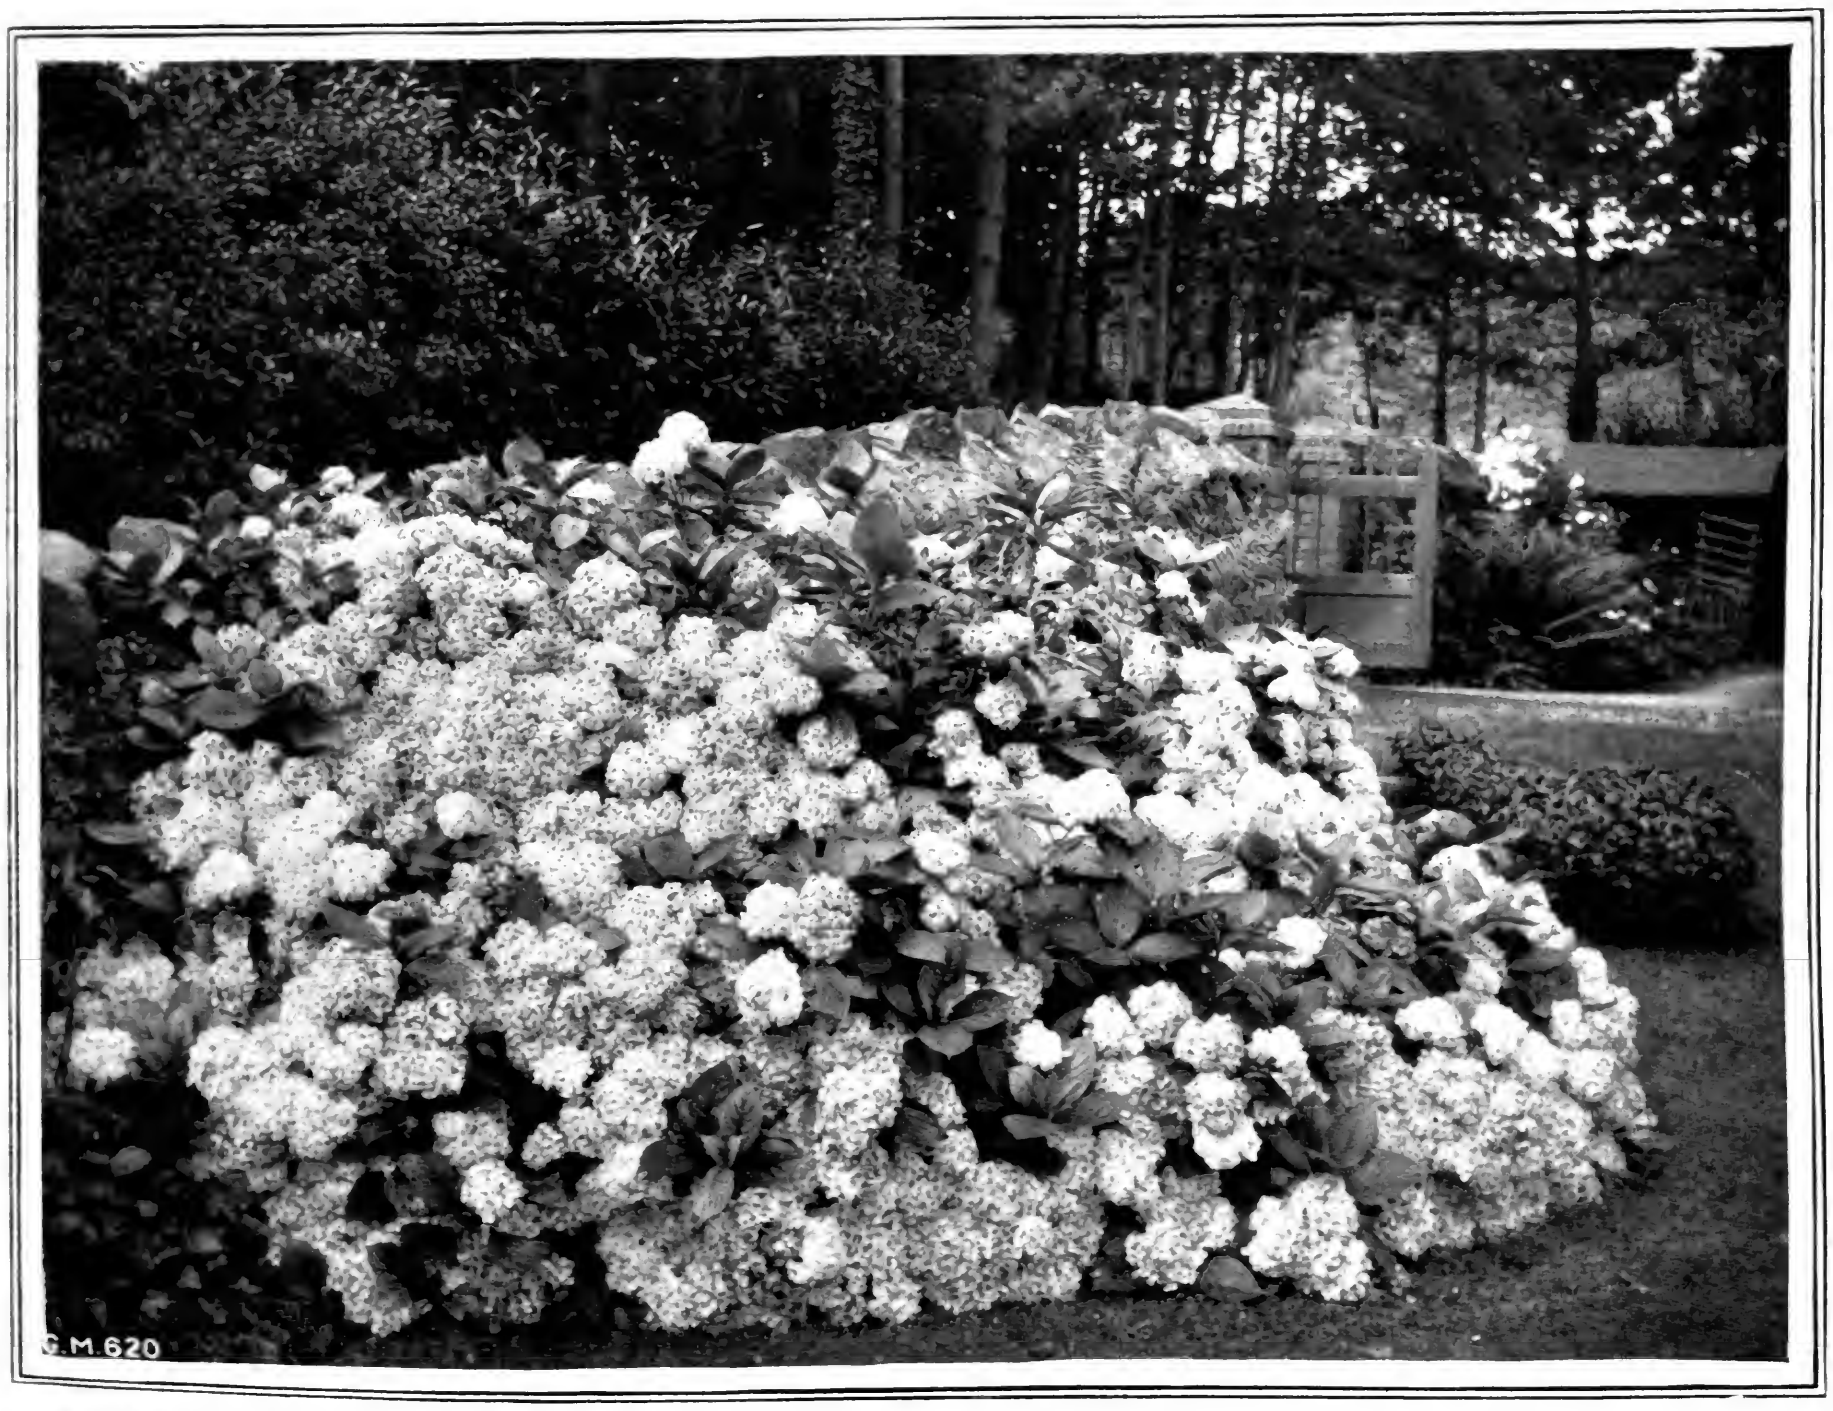
Hydrangea Bretschneideri, also known as H. pekinensis and H. pubescens, is a strong-growing bush, with flattened corymbs of whitish flowers. Though ornamental, it is less showy than most of the others.

Hydrangea petiolaris (or scandens) is remarkable for its climbing habit, and the fact that it will attach itself to a wall by its aerial roots much as the ivy does. The large flattened corymbs of flowers are not unlike those of the elder, plus some large sterile blossoms around the outside of the cluster. It is quite hardy, and makes a good wall plant.

More remarkable for its leaves than its flowers, Hydrangea quericifolia is well worth attention where a sheltered and fairly moist spot can be found, as it is of a more tender nature than the other species from North America. The leaves are deeply lobed after the manner of the American Red Oak, while the flowers are white. Hydrangea radiata is somewhat like H. arborescens, from which, however, it differs in the foliage; as in H. radiata, the undersides of the leaves are of a vivid bluish-white tint. When stirred by the wind this feature is very noticeable.

Hydrangea Sargenti, a new species which was introduced from Western China by Mr. E. H. Wilson, V.M.H., was given an Award of Merit at the International Exhibition last May. It is one of the most distinct of all hydrangeas, being a very robust grower, with exceedingly large leaves, dark green above and paler beneath, while they are clothed on both surfaces with hairs, so that they have a quite velvety appearance. A singular feature is the scale-like hairs on the stems and leaf stalks. The flowers are borne in a large flattened corymb, and consist mainly of small fertile ones of a bluish-lilac tint, the sterile and showy ones being limited to a few around the outside.

W. T.



A FINE SPECIMEN OF HYDRANGEA HORTENSIA IN THE GARDENS AT TY NEWYDD, TORQUAY.

Mdme. Renée Gaillard, which is herewith illustrated, has been several times shown at the meetings of the Royal Horticultural Society by Messrs. T. S. Ware, of Feltham, and is of much the same colour. In the accompanying illustration the deep serratures can be plainly seen. Other good varieties worthy of especial mention among these Continental forms are Bouquet Rose, deep rose; E. G. Hill, soft rose, of great promise as a market plant; La Lorraine, very large flowers of a soft rose colour; Liberté, pink, much fringed; Mont Rose, clear rose; and Richesse, bright carmine-rose.

Beside these a number of new varieties were shown by M. Moullière at the International Exhibition last May, among which the following stood out prominently: La Perle, white, deeply toothed; Lillie Moullière, rich rose, light centre: Directeur Vuillermet, rich pink, much serrated;

CULTIVATION OF ASPARAGUS.

The ever-recurring quest of the market grower is a crop that it will pay him to cultivate. At times he discovers a very profitable subject for cultivation, and is not backward in exploiting it for all it is worth. So it occurred with cucumbers and tomatoes, both of which have now had their day. And even in the case of the Kentish strawberry growers, there are not lacking signs of incipient decay in this culture in the county of nuts and hops. No doubt, the public taste creates a demand for a certain article, while in other cases the market grower himself can boldly produce a particular fruit or vegetable, and wait contentedly for the demand, which he is assured will ensue.

Yet it is not an easy matter to find a crop that will answer this purpose so easily. The Kentish strawberry growers, for instance, did not anticipate the extensive development of this industry in Hampshire, nor the consequent fall of their produce from its former high place. Certainly, strawberry growing in Kent is not what it used to be; the acreage under the fruit is rapidly decreasing, while, on the other hand, in the Southampton districts, tremendous strides are being made in the extension of the culture, it having been discovered that the soils thereabouts are particularly favourable to the production of early crops. Already have we mentioned the relation which exists between the public taste and the demand for a certain fruit or vegetable. In many cases, of course, a certain taste has to be acquired, as, for example, had that of the tomato, and so, by degrees, the culture becomes more and more prominent.

This is what is happening now in the case of asparagus. Many people have already cultivated a taste for "the soothing effects of the mucilaginous juice" of asparagus, although there are a great many others who still have that taste to acquire. It is a very wholesome vegetable, and even possesses some medicinal properties that have formerly been quite unsuspected. That very critical journal of medicine, the "Lancet," says there is no evidence to condemn this peculiarly agreeable vegetable; though we were unaware that anyone wanted to condemn it at all. However, it goes on to say that, according to certain old text-books of homely medicine, asparagus is a useful stimulant to the kidneys, and exercises a gently sedative effect on the heart, calming palpitation and nervous excitement of that organ.

Usefulness of Asparagus.

Comparatively modern research has also demonstrated that it is the asparagin, an active principle found in potatoes, marsh mallow, liquorice, belladonna, as well as in asparagus, which acts as a palliative in the heart affections which are attended with excited action of the pulse; while it is further stated that "the soothing effects of the mucilaginous juice upon the mucous membranes of the mouth and pharynx add to the virtues of the tender shoot." Altogether, it seems that scientific evidence recommends asparagus as a wholesome and valuable addition to the diet.

On the lines of the argument mentioned above in reference to tomatoes, it may quite confidently be assumed that asparagus culture will become more and more prominent as the taste for the vegetable is acquired by the general public.

Were we to assume that a few isolated examples were indicative of the ordinary value of asparagus it would certainly appear that to eat some "grass" is to eat gold. At the Evesham (Worcester) Asparagus Show, in 1912, the record price of £10 10s. was paid for a bundle of 120 heads of asparagus which won the challenge cup there. This is at the rate of 1s. 9d. per head. Usually the best quality asparagus from the Evesham market realises from 20s. to 50s. per bundle; but, of course, it is clearly evident that the profit or loss that may accompany this culture depends, to a very large extent, upon the skill and capabilities of the grower, and the fact must not always be taken for granted that the crop is one which can be grown with the certainty of returning a profit.

Asparagus Culture around Evesham.

The reader may perhaps be aware of the fact that asparagus forms the chief source of revenue for the support of many families in the fertile valley of Evesham, where there are nearly one thousand acres of land devoted to this crop. And it is stretching no point to imagine that there are in this country many tracts of land almost, if not entirely, as suitable for asparagus culture as the Vale of Evesham. Certainly, at the present day, by far the best quality "grass" that finds its way to Covent Garden, whether from home or abroad, hails from this "happy valley," although, as regards size, the French growers around Toulouse and Paris hold the palm.

Smallholders in this country have been advised to specialise in certain remunerative crops rather than attempting to grow a great many different varieties of vegetables or fruit. Here, then, is a subject which appears to be eminently suited to their requirements. The capital outlay in asparagus cultivation is not great; in fact, it is less than that involved in many other "special" cultures. In France, it is cultivated, not only in gardens, but in the open fields, in many of those districts where the soil is favourable to its production. There is little risk involved in the growth of asparagus, for it suffers much less from disease than many other crops, and on the Continent its production is found to be chiefly in the hands of the smallholders.

Old Basing. J. C. Newsham.

(To be continued.)

Broad Beans.—A sowing on a warm, sheltered position should be made as soon as the ground is in suitable order for drawing the drills. Royal Cluster is a good variety for an early sowing. Further sowings should take place according to requirements. Where the condition of the soil does not permit of outdoor sowing, the seed may be sown in given in moderation to pot plants until the young plants appear, when they should be gradually hardened off preparatory to planting out.—W. Messenger, Woolverstone Park Gardens.

DAHLIAS: THE VALUE OF AN EARLY START.

Dame Fashion generally decrees that some particular flower will be honoured by her each year, and, though she is a fickle jade, rumour has it that she has taken up the dahlia for 1913. It is quite time she smiled on this fine old flower, and now that there are several new types, with endless varieties, most of which are very beautiful, to add to the older favourites, the claims to attention are amply justified.

The object of these few notes is to emphasise what would, I am convinced, do more to make dahlias fashionable or popular than anything else. I refer to growing the plants early. One can never expect that any flower which heralds autumn to be the fashionable one of the year, yet this is the season with which the dahlia has hitherto been associated. It is time we got rid of that idea, for, as it is quite possible to have dahlias in bloom in July, and a continual display thereafter until the plants are cut down by frost, why, then, I ask, should we wait until September before reaping the harvest of pleasure which a display of these charming subjects will undoubtedly give?

To obtain plants to commence blooming early in July, it is imperative that cuttings be inserted in February or at latest very early in March. Old roots, started in moderate heat about the middle of March, and given proper attention afterwards, will come along at the same time. Because one has worked on the old rule, and started the plants in March, rooted the cuttings, and planted them out of 3in. pots towards the end of May, that is no good reason why the rule should be adhered to.

The aim should be to have plants well established in 6in. pots and upwards by the end of May, then one can reasonably hope, given proper care, to see a few blooms before July is far advanced. In gardens where convenience permits of this being carried out, there is no more difficulty, except for the extra potting, to have them in this condition than in 3in. pots.

One can sympathise with the amateur who takes up the culture of these beautiful flowers as a hobby, but who lacks facilities for giving them proper care and attention. He probably plants his old tubers straight away in the garden late enough to escape the danger of frost, or possibly purchases his plants from a nurseryman, in thumb pots, or at largest in 3in. pots, just before planting time. My advice in that case would be to decide how much can be spent in purchasing plants, and then arrange with a nurseryman to pot the plants early.

For my part, I would infinitely prefer one strong plant, well rooted in a 7in. pot at the end of May, than four plants in cutting pots. The latter may flower the same year, or they may not, but certainly not until very late. For the future popularity of the dahlia nurserymen should impress upon their customers the necessity of purchasing early plants and potting them, or they should charge a higher price and supply strong plants in 48's or 32's, which would, I am certain, in the long run, be the most profitable, and also give the maximum amount of pleasure. A. J. Cobb.

Coleus from Seed.—Given a pinch of seed from a good collection, one may raise an extensive variety of different forms. A great advantage is that they grow very quickly, so that seed sown in the spring will give a number of effective plants that will make a good display in the greenhouse during the summer.—S. W.

MELON CULTURE.

The cultivation of melons is an important matter in most private gardens, for during the summer and autumn months no dessert is complete without them. Provided plenty of heat is at command their cultivation presents few difficulties, and they can be had in perfection from early in May until late October.

For early supplies a lean-to house facing due south is to be preferred, but for general crops a span-roof house is preferable. A fair amount of bottom heat is very desirable for melon growing, and this is best provided by hot-water pipes beneath the bed in which the plants are growing. Failing this a hotbed of fermenting material must be provided, but where hot-water pipes are used it is well to make up a good bed of oak leaves above these, using a perforated iron trellis to keep the leaves from the pipes.

To grow melons well, it is by no means essential to provide a large amount of root room. If the border is 18in. wide and 8in. deep, it will be sufficient. This should be composed of good turfy loam of a medium texture, the turves cut 4in. thick. Do not chop them to pieces, but make up the border with them intact. Small mounds should be placed on the bed at suitable intervals, in which to plant the melons. Loam broken up and mixed with a little old mortar rubble or wood ashes is all that is necessary. I do not advocate the use of manure, as this tends to create rank growth, which I believe encourages gumming and canker. The aim should be to build up a sturdy, vigorous plant, capable of perfecting a full crop of fruit.

Place two seeds in a 3in. pot, plunge the pots in a warm propagating case, and, when the seedlings appear, transfer them to a position near the glass. The stronger one must be retained and the weak plant cut off near the soil. Guard against cold draughts, and at no time allow the temperature to fall below 65 degrees; indeed, a rather warmer atmosphere is to be preferred. Place the young plants in 48-sized pots when nicely rooted, and encourage them to make sturdy growth. Regular syringings with tepid water during bright weather are beneficial. Should green-fly appear dip the young plants in a weak solution of quassia extract.

When nicely rooted plant out the melons on the mounds of soil already prepared; the latter should not be more than two feet from the roof glass. Stake and tie the plants and water them in with tepid water. Should the bottom-heat ever become excessive after the melons are planted, it may be necessary to slightly raise the mounds with a fork, but after a day or so press the soil down again firmly. It is best to grow early melons on single stems, so let the main growth reach the top of the trellis before it is stopped. When the plants are well advanced no harm will be done if the temperature rises to 90 degrees with the sun's heat, but the house must be kept frequently damped down. Midday, when the sun is bright, is the best time to fertilise the flowers. Always endeavour to perform this operation when there are three female blooms open together on each plant, for if they are fertilised at different times those set first will swell away and half-starve the later ones. Discontinue syringing during this period, and admit a little air to maintain a light, buoyant atmosphere. Pinch the laterals at the first leaf beyond the fruit, and carefully remove superfluous growths at an early stage, but reckless cutting away of shoots is sometimes the cause of gumming and canker.

When the fruit has set syringing may be recommenced to keep red spider in check besides encouraging growth. Feed the plants regularly with liquid manure. Some roots will probably have appeared on the surface of the bed by this time, and a light top-dressing of loam with some approved fertiliser added will be a great assistance.

If canker appears on any of the plants treat the affected parts with quicklime. Strong healthy plants grown as described are rarely, if ever, attacked by this disease. It is not necessary to shade melons at any period of their growth, unless it is necessary to retard their development. As a rule, three fruits on a plant are sufficient when good specimens are desired, and while the fruits are ripening a rather dry, airy atmosphere is essential to develop the best flavour. Good varieties are numerous, but for general use The Peer, Superlative, and The Countess can be recommended.

Batsford Gardens. J. Gardner.

KOHL RABI.

This useful vegetable is now finding more favour in private gardens than formerly, and one reason is that it has been brought into a more useful condition by drastic selection. It is now a valuable addition to kitchen garden crops, and is particularly useful if there should be a shortage at any time with turnips. When about the size of a tennis ball, and quickly grown, kohl rabi makes a tender and distinct dish. Sutton's Earliest Green is an excellent variety to grow for summer and early winter use, with Sutton's Purple for autumn and winter, as this appears hardier than the green variety.

KOHL RABI.

Sutton's Earliest Green, a useful and distinct summer vegetable.

For ordinary use sow the seeds during March for summer crops, and in August for winter crops. Sow in drills or broadcast, as winter greens are sown, and when large enough to transplant, transfer the seedlings to ground that has been well prepared, as quick growth is essential. Allow a distance of eighteen inches between the rows, and a foot from plant to plant. Hoe frequently. To economise space lines can be planted in the alleys that are usually formed between various seed beds. The winter batch, when of a suitable size for the table, should be carefully lifted and handled, and stored in a cool place.

George Ellwood.

Swanmore Gardens.

Variegated-leaved Oleander.—As a substitute for a croton, this oleander, which will thrive under much cooler conditions than crotons in general, can be well recommended. The long, narrow, deep green leaves are freely variegated with gold, and dwarf plants on single stems are well adapted for table decoration. It is an old variety, but I have of late met with it in better condition than ever before.—T.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

DECIDUOUS CALANTHES.—The stronger-growing calanthes, such as C. vestita, C. Bryan, C. W. Murray, C. Veitchi, C. Harrisi, and the more recently-introduced C. Angela, are now producing their new growths, and as soon as the roots make their appearance the plants should be repotted. It is advisable not to allow the new roots to become too far advanced, as they are easily damaged in the process of repotting. Where calanthes have been turned out of their pots and stored in boxes, as suggested in a previous note, the new roots get away into the sphagnum, and may be easily lifted and carefully repotted with the sphagnum attached to the roots. If the plants remained in the pots in which they were grown last season, they must be turned out, all the old potting compost must be carefully removed and the old roots cut back, only sufficient being retained to secure the plant in position in the new compost. Before repotting carefully examine the pseudo-bulbs for scale or other insect pests, which may have secreted themselves about the base.

THE COMPOST used may be varied according to the conditions under which the plants are grown. I cannot lay down any hard and fast rule, because, having had charge of plants in various parts of the country, and under different conditions, I have found that we have to determine for ourselves the most suitable compost. There is also the constitution of the plants to be considered. There are numerous varieties and hybrids, and some of the finest we have are very difficult subjects to manage. In the case of C. Oakwood Ruby, the late Mr. James Douglas told me Mr. Cookson had on several occasions given him plants, but he was unable to keep them for more than a year or two. I could mention many who have had similar experiences with this variety, and there are other varieties equally difficult to manage. With the weakened constitution, probably brought about by constant inbreeding, the provision of suitable potting material and conditions can only be arrived at by experience. We find a light compost the only suitable one, with ample crocks, charcoal, and sand, to render the whole porous. For the stronger-growing kinds we find a compost of equal portions of fibrous loam, peat, and chopped sphagnum moss suitable. This should be pressed moderately firm. In selecting pots of a suitable size one should always give sufficient root space unless a second potting is given about the end of June. Watering should be very carefully done until the new roots become well established in the potting compost. Then more liberal treatment may be given. To increase the stock any back pseudo-bulbs that have been removed from the plants should be laid in boxes on a bed of chopped sphagnum and silver sand, carefully labelled. These generally produce good strong breaks, and may be potted as soon as new roots appear.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

ACALYPHA HISPIDA.—Grown either as a summer or winter decorative subject, this delightful plant, with its beautiful crimson tassels, always repays good cultivation. As standards for summer use single-stemmed plants of last year's stock may be reduced to the required height, kept somewhat dry at the roots, and in a growing atmosphere until they break, when they may be repotted. Allow four or five growths to grow away unstopped, and as they produce their plumes, keep them in a temperature of 60 to 65 degrees by night and a little higher in the day, where damping between them may be frequently practised. Avoid damping overhead or the tassels will "damp off." For autumn and winter use cuttings of the young growths may be taken when available; they will quickly root in a close propagating pit, and should eventually be potted into 8in. pots. At a height of fifteen inches we pinch out the points of growth and allow the best three of the resulting growths to remain. A compost they do well in consists of four parts fibrous loam, two of leaf-mould, two of peat, one of sand, and a little well-rotted manure.

ANTHURIUMS.—These plants will now require attention, and should be repotted or top-dressed as may be necessary. The material we have recently used successfully consists of equal parts of fibrous loam, osmunda fibre, and chopped fresh sphagnum moss, with a little sand. Tall-growing kinds, such as A. Waroqueanum, A. Veitchi, and A. Andreanum, are best grown in pots, which must be well drained; the material should be worked carefully between the roots within the pot, and made firm, and from the rim of the pot to the lower leaves it should be worked in pyramidal form, and bound tightly with twine, which will last until the roots have taken a firm hold of the compost. A. Scherzerianum and its forms are better grown in pans, and when finished the crown should be slightly above the pot rim. Moist conditions, the frequent use of the syringe, and a temperature of 70 to 75 degrees, rising as the weather gets warmer, will suit admirably.

EUPHORBIA JACQUINIÆFLORA.—Good cuttings may be inserted from now onwards until the required number are rooted. Water the stock plants only when very dry, and keep them in full sunshine, but use the syringe to induce them to break freely. Cuttings should be taken when four inches in length; cut them closely to the old stem, and insert, as they are taken from the plant, in saucers of silver sand which has been previously watered. Place in a propagating frame within a house or pit, over bottom-heat of 70 to 75 degrees. Provide a close, moist atmosphere and shade in the day to prevent flagging; give a little ventilation on mild nights to prevent damping, and they will soon root. Pot singly in small pots, using soil as for acalyphas, and for a few days return them to the close frame. Afterwards they may be grown in a night temperature of 60 to 65 degrees, rising to 70 degrees by day, shading at 75 degrees. Use the water-pot very carefully.—H. Prime, Hatfield Gardens.

THE FLOWER GARDEN.

ANNUALS.—Another sowing of annuals must now be made, consisting of varieties of asters, Phlox Drummondi, ten-week stocks, Dianthus Heddewigi, cosmos, zinnias, etc.; these can be treated in a similar manner to that advised in my notes a month ago for other kinds requiring a longer season of growth, many of which will now be far enough advanced for pricking off, and should be attended to as early as possible.

TUBEROUS BEGONIAS.—Preparations for starting the corms of these useful bedding subjects must now be considered; place them thinly in boxes containing leaf-mould, in such a manner that the top of the corm is only very slightly covered; afterwards remove them to a warm house or pit, damping occasionally to keep them moist. Under these conditions they will soon commence to grow, and will then require potting, or preferably planting out into a frame or pit; one which has been used for violets will be found very suitable. For some little time after they have been transferred to a pit or frame, care must be exercised in ventilating; as much sun-heat as possible must be retained by closing up the lights in good time whenever air has been admitted on bright days. This practice will help to maintain a comfortable temperature. Very little water will be needed once they have been well watered in, until growth has advanced; a slight damping over at closing time will be beneficial to them. As the days get warmer, ventilation can be gradually increased, so that by bedding-out time they will have become accustomed to exposure to the open air.

LAWNS.—As the mowing season is approaching lawns must be well swept and rolled, in order to remove any grit or small stones which may have been left from top dressings. Owing to the mild winter, so far experienced, there appears to be more grass than usual on the majority of lawns, and it will greatly improve their appearance if the mowing is done at once. Turf edgings to beds and walks must now be trimmed, and if the latter are at all weedy or mossy the first opportunity of settled weather should be taken advantage of to dress them with a weed destroyer.—T. B. Field, Wych Cross Place Gardens.

FRUITS UNDER GLASS.

THINNING FRUITS.—This most important operation exerts a powerful influence upon colour, and where colour is imperfect, quality is generally second-rate. Evil follows over-cropping of grapes, peaches, melons, figs, apples, pears, etc., the fruits remaining more or less small, flavourless, and deficient in colour. Dropping of peaches at stoning time is often the result of overcropping; forced figs play the same tricks, and one might multiply instances of similar loss of quality from the same causes. Sufficient has been said to remind the amateur and beginners that they must be merciful; quantity alone is of no use, we must have quality also. Bad culture may sometimes cause a collapse, but in most instances overcropping is the chief cause. The thinning of grapes, peaches, and other fruits has just commenced, and all fruits will pay for judicious thinning, which will also preserve the health and vigour of the trees. Postponement of this work is also a waste of strength. Too light cropping, on the other hand, is equally bad practice, especially in the case of vigorous young trees. Any competent man should be capable of thinning sufficiently to ensure a full crop of excellent fruit without distressing the trees or allowing them to become too gross.

PEACHES.—Disbudding demands almost daily attention early in the spring, and may be carried out conjointly with thinning until each fruit and shoot has ample room for full development. The framework of young trees can only be formed by most careful and judicious disbudding. Healthy trees are fit for disbudding as soon as the fruits are set; on the other hand, if the trees break weakly, disbudding should be deferred until the roots and sap become more active; the little-and-often system is the best. Tie down the shoots as they increase in length, but do not overcrowd the trees with young growths; six inches or more apart is none too much. If the weather be mild the temperature may be advanced to 60 degrees at night in the early houses, but in cold weather be content with 55 degrees. Endeavour to secure a temperature of 75 to 80 degrees at closing time, with plenty of moisture; syringe the trees twice a day with tepid soft water. Later trees, which will come into blossom this month, should have a little fire-heat at night and during dull weather to assist the blossoms in setting and to exclude frosty air during the period of fertilisation.

EARLY PINES.—It will be necessary now to help all those Queen pines forward which have thrown up their fruits, by daily attention to the most trifling details. Once the flowering stage is passed the roots will take more frequent supplies of tepid liquid manure, guano and soot water, and very light dewings overhead on bright days may be given. March and April being so changeable, no fixed day or night temperature can be kept, but the minimum should range about 70 degrees, with 80 to 85 degrees by day when sun-heat favours ventilation.—F. Jordan, Warter Priory Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

The Horticultural Club.

On Tuesday, the 4th instant, after the usual monthly dinner, at which Mr. W. B. Cranfield presided, and a good number of members and guests were present, Mr. Edward A. Bunyard gave a peculiarly interesting lecture on "The Introduction and Development of Some of Our Hardy Fruits," illustrated by a large number of lantern slides. The peculiar interest of the lecture consisted in the fact that Mr. Bunyard dealt with the subject not merely from the practical point of view, with which he is particularly familiar, but also from the historical point of view derived from a deep study of classical records, and those embraced in ancient sculpture and mediæval illustrations which have been preserved, as tangible evidence of the fruits of very ancient and more modern times. Several maps of Europe and Asia were employed to demonstrate the varied routes by which some of our familiar fruits found their way from the East, where they appear mostly to have originated, through Europe, and eventually to America. A region, of which Armenia appears to have been the centre, seems, curiously enough, to have been, so to speak, the birthplace of most of these fruits, and the records have enabled the lecturer to trace their spread from point to point as determined by emigration and immigration of the various tribes and nationalities who were sufficiently civilised to appreciate them and carry them with them as they proceeded. Singularly enough, even philology has played a definite part in these records, the names originally given being, despite marked differences, induced by their own association with foreign languages, still recognisable by the expert in their modern guise. The fig, for instance, though the F has been changed into V, H, or other letters to suit the spirit of the languages of adoption, being practically the same all over the world; while the apricot is equally recognisable through many perversions when it is known that the "a" is merely the equivalent of the Arabic "al" for "the," the rest of the word being phonetically similar to the original name as far as this can be traced.

In ancient sculpture, Egyptian and others, certain fruits are plainly shown, while in more modern but still old specimens, as well as in illustrations, some varieties even are distinguishable. After dealing with his subject from this point of view, the lecturer showed a series of photographs of the wild species of apples, pears, plums, peaches, almonds, cherries, etc., and gave some curious data as to the relative capacity of these to afford "sports" or "mutations," and so facilitate the acquisition of new varieties of which in these days we have such an abundance. Some, such as the sloe, appear to be incapable of advance, while to another member of the same genus we owe all, or nearly all, of our wealth of plums.

Such very different fruits as the peach and the almond appear to be botanically identical, and it can only be assumed that we owe the juicy flesh of the former to some such sudden "mutation" in the hard, acrid flesh or outer shell of the latter, as rendered the individual plant worthy of cultivation as a sweet, pulpy fruit rather than a nut. A flat form of peach was also shown, which can only reasonably be imputed as a similar "mutation," as a slightly flattened fruit would hardly have been considered worth collective breeding to enhance the character. The lecturer was indeed in favour of the opinion, which of late years has been largely strengthened, that "mutations" or sudden "sports," capable of reproducing themselves truly by their seed, have played probably quite as important a rôle in fruit development as simple continued selection of small differences.

In the subsequent discussion, in which Messrs. Chas. T. Druery, C. Pearson, W. B. Cranfield, and a visitor, Mr. Leonard Coates, from California, participated, Mr. Druery strongly supported the "mutation" theory, in view of his long experience of such phenomena in connection with our native ferns, in which many hundreds of such cases are recorded, and he also endorsed the lecturer's opinion that these sudden changes could not in our present state of knowledge be imputed to culture, or indeed, to any definite cause whatever. He also drew attention to the singular fact that all the fruits dealt with, and many others, belonged to the great rose family, to which we were so immensely indebted for a host of our most beautiful flowers.

Mr. L. Coates gave some interesting data concerning the introduction of fruits into North America, in California particularly, and the experiments which, generously aided by the American Government, they are carrying on with a view to increase the number of really hardy varieties, capable, by virtue of their hardiness, of being grown to advantage over much wider areas than at present.

A very cordial vote of thanks was accorded to the lecturer, and the hope expressed that the Club might speedily be favoured with further data on similarly interesting lines.

Scottish Horticultural Association.

The monthly meeting of this association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 4th inst. Mr. King, the president, was in the chair, and there was an attendance of 75 members. A paper on "Dry Wall Gardening," by Mr. Thomas Smith, Coombe Court Gardens, Kingston Hill, Surrey, was read by the Secretary.

Dry walls, Mr. Smith said, as a means of growing some kinds of rock plants, had much to recommend them, as the maximum of sunshine could be had, and the plants were practically immune from the baneful effects of excessive moisture in winter. Moreover, the dry wall could be introduced where there was not room for the more elaborate type of rock garden. The material necessary for its construction, too, was generally easily procurable, rejected paving stone, or even ordinary brick, serving the purpose where better material could not be obtained. The best material, however, was rough, unhewn stone, direct from the quarry, in blocks varying in thickness and length. The best form was that of the retaining wall, for the existence of which not only might natural reasons suggest themselves, such as supports to terraces, etc., but the mass of soil behind yielded a constant supply of moisture to the roots of the plants. A double-faced wall could also be adopted in order to form a boundary to something else, as was done at Carberry Tower, where such a wall bounds a geometrical garden. In building the wall, the stones should be bedded with soil, joints from one to two inches being left between them according to their size, and the plants should be inserted in the course of its erection, as much larger plants could thus be used, and their roots could be spread out better.

The correct batter for the wall was 1½ to 2 inches to each foot in height, and if the soil was of a non-porous nature some drain pipes should be laid through the base, with some rough rubble behind, to give egress to surplus water. Mr. Smith also referred to the advisability of drawing up a colour scheme before planting, as there was nothing more disappointing than a promiscuous arrangement of the plants, and he also gave a list of suitable subjects for using in dry walls.

On the motion of Mr. Berry, Mr. Smith received a very cordial vote of thanks.

The exhibits were: Camassia esculenta, var. præcox, from Mr. R. H. Cockburn, Gartmore Gardens, Perthshire; group of rose "Richmond," from Messrs. Todd and Co., Edinburgh; and rhododendrons from the open air, from Mr. A. Johnstone, Hay Lodge, Edinburgh.

At the meeting on April 1, Dr. Hamilton, of Bournemouth, will give an autochrome lantern lecture entitled "Some Gardens of Bournemouth and the New Forest."

Surbiton Spring Show.

Spring flowers have a great attraction for all of us, but their hold upon the general public is greatly increasing. One has but to notice the many spring flower shows now held as compared with a few years ago, or the advancing position of those societies that have made spring flowers a feature and are conducted on broad lines, to discover how widespread is the interest. Commenced as a quite small venture four years ago, the Surbiton and Tolworth Society now holds the finest spring flower show in suburban London. The district is a good one for gardening, the gardeners are all keen men, Mr. Zimmern is a generous president, and Mr. Lionel Perkin an indefatigable secretary, hence the success and the fine display in the Surbiton Assembly Rooms on March 11 and 12.

Daffodils are the great feature, and practically all classes of these flowers are well represented in professional, amateur, and ladies' classes, and grown in fibre as well as in soil. Hyacinths fill a large spare, but, owing to the past season, were not so good as usual on this occasion. Cinerarias, azaleas, tulips, amaryllis, primulas, and groups for effect have classes provided for them, and all help to widen the interest and add to the attractions of a vernal display.

There were no fewer than five groups in competition, and Mr. Brill, gardener to F. S. Bristowe, Esq., Chalcott House, Ditton Hill, won first place with a very light and pleasing display, composed largely of acacias, cinerarias, arums, spiræas, Primula malacoides, and daffodils; a little better finish to the margin would have improved matters. Mr. T. Smith, gardener to the Marquis of Ripon, Coombe Court, Kingston Hill, gained second prize with a rather heavy group, in which lilacs, wistarias, pyruses, etc., were leading features; Mr. A. Corp, gardener to A. Zimmern, Esq., Oak Hill Drive, Surbiton, third.

Mr. Corp scored for a dozen hyacinths, and he had splendid spikes of La Grandesse; Mr. T. Hainge, gardener to R. A. Hewat, Esq., Souachan, Surbiton, came second; and Mr. Hawkes, gardener to W. Williams, Esq., Albury House, third.

In the class for three pots of daffodils, trumpet varieties, the competition was unusually keen, and splendid blooms were staged. Mr. Burfoot, gardener to Mrs. Windeler, Dit on Hill, gained first prize with Glory of Leiden, Mdme. Plemp, and Victoria; and Mr. Hainge followed with Mdme. de Graaff, Glory of Leiden, and Victoria; while Mr. Corp had to be content with third place. There were eleven splendid entries. For daffodils, three pots, not trumpet sorts, Mr. F. Lock, gardener to Miss Price, Tandridge House, Surbiton, scored with Sir Watkin; Mr. Burfoot second; nine entries.

Mr. Lock had the best three pots of single tulips, showing Proserpine finely; while Mr. H. Mustchin, gardener to T. Salter Cox, Esq., Lovelace Gardens, Surbiton, came second with the good old Keizers Kroon; ten entries. Mr. Burfoot had the best double tulips.

Mr. G. James, gardener to Baron von Ernsthausen, Manor Farm, Ditton Hill, won Messrs. Carter's prize for a pot of King Alfred daffodil, and Mr. Burfoot won Mr. C. Bourne's prizes for six varieties of daffodils, five blooms of each, his best being Victoria, Glory of Leiden, Sir Watkin, and Beauty.

Mr. L. Perkins' prizes for hyacinths were annexed by Mr. Fielder, gardener to W. Hudson, Esq., The Lodge, Surbiton Hill; and Mr. W. H. Park, Sandilands, Surbiton.

Messrs. Cartwright and Goodwin, Kidderminster, won the silver challenge cup with a very fine group of daffodils, wherein Glory of Noordwyk, Fairy, Aspasia, Goldfinch, Horace, Castile, Southern Light, Armorel, Cordelia, Long Tom, and other good things. Mr. Christopher Bourne, Bletchley, came second with a charming set that included Stephen Phillips, Mrs. J. H. Veitch, Cornelia, Weardale Perfection, Lucifer, Gloria Mundi, and Evangeline.

Mr. Corp had a huge pot of the poetaz daffodil Elvira, carrying about a hundred spikes of its white flowers; he gained a first prize; and Mr. Hawkes came second with Victoria finely grown. The class for six vases of daffodils was an unfortunate one, as a good set was disqualified, two vases appearing to contain flowers of the same variety; so Mr. C. Burfoot led with Mdme. de Graaff, Maximus, Mdme. Plemp, Glory of Leiden, Vanilla, and Victoria.

Bulbs grown in fibre made a glorious display in the upper room where, with plenty of light, they showed up finely. We may make mention of a fine bowl of Barri conspicuus, shown by Mr. Palk, with five-and-twenty flowers; a fine pan of Sir Watkin from Miss A. C. Fuller, 9, Palace Road, Surbiton; and a superb pot of six bulbs of this variety from Mr. C. Burfoot, with twenty superb flowers; Mr. Lock's pan of Mdme. de Graaff, and Mr. Burfoot's big bowl of Glory of Leiden; Mr. James's pan of Gigantea hyacinths, and Mr. Hawke's fine bowl of the poetaz daffodil Aspasia. Mr. Park mixed tulips with his Innocence hyacinths, and so lost a first prize, because he showed two kinds instead of two varieties of bulbs.

There were thirteen table decorations, and Mrs. J. Smitt, Coombe Court Gardens, Kingston, led with pink carnations; Mrs. Harold Tronncer, Flockholme, Ditton Hill, second, with anemones; and Mrs. A. Farmer, Tolworth, third, the latter showing daffodils.

Messrs. J. Carter and Co., Raynes Park, filled a corner with a beautiful group of King Alfred daffodils, margined with crocuses, and with a retaining rockery wall in front. Mr. L. Perkin, Surbiton, displayed a collection of daffodils, and his flowers, though bright and clean, were a trifle small. Messrs. Barr and Sons, Covent Garden, had a good set of King Alfred, Aspasia, Fairy, Bedouin, Amazon, Firelight, Sunrise, Mermaid, and Southern Star. Some alpines and Chionodoxa sardensis added to the attractions of the display.

Reading Gardeners' Association.

At the fortnightly meeting, which was held in the Abbey Hall (by kind permission of Messrs. Sutton and Sons) there was again a good attendance. The President occupied the chair.

The lecturer for the evening was Mr. J. T. Tubb, The Gardens, Bear Wood, and his subject was "Roses." In opening, Mr. Tubb referred to the brief and unassuming title of his paper, stating that, although the title was brief, the subject was wide and formidable, so much so indeed that it was impossible to deal adequately with it in the course of a single evening. Touching briefly on the history and antiquity of the queen of flowers, Mr. Tubb spoke of the wonderful achievements wrought by rose specialists during comparatively recent years, which have given us the marvels to be found in large numbers among all the different groups of the rose family at the present day. Hybrid Perpetuals, Teas, Hybrid Teas, Noisettes, Polyanthas, Wichurianas, and other classes have in a couple or three generations been improved out of all knowledge. Mr. Tubb gave the benefit of his experience with reference to selecting the site for a rose garden, and the preparation of the ground; the making up and enrichment of the soil and the best manures to use. The best season for planting and transplanting was in the opinion of the lecturer from October onward, and he himself preferred the months of October and November. Very careful attention should always be given to planting; the operation should always be deferred until the ground was in a proper condition to receive the plants. No greater mistake can be made than to plant in wet soil. The subject of stocks, pruning, disbudding, protection in winter (though with the latter the lecturer had no sympathy) were all ably dealt with, and the advice given with reference to the eradication of insect pests was most exhaustive.

An excellent discussion followed the lecture, and Mr. Tubb received a hearty vote of thanks at the close of the meeting.

Mr. F. Townsend, head gardener to the vice-president, exhibited well-grown seakale.

The annual tea held recently was a great success, about 100 members and friends sitting down. At the entertainment kindly provided by the vice-president and sustained by artistes from London, an audience of upwards of 600 assembled. The varied programme was much enjoyed by all present.

Croydon Gardeners' Society.

There was a capital attendance of members at the recent meeting, when a very interesting lecture, entitled, "Then and Now," was given by Mr. J. Gregory, F.R.H.S. Mr. Gregory, from a very wide experience in horticultural matters, was able to contrast the methods of culture in use over sixty years ago with the practice of the present day. In his boyhood days the love of Nature and Nature studies claimed him as a devotee, and in the northern town where his early life was spent the enthusiasm for flowers was grafted into his mind by his surroundings. Apparently in the northern towns keen competitions were held, and, although flower shows were not then of such extensive magnitude as they are now, the rivalry amongst growers was sufficient to induce each exhibitor to produce his best. In those early days a grower had not the conveniences that he has now, and his battles were won under circumstances more adverse than they are at the present time. Dogged pluck and strenuous labour—a character always uppermost with the good cultivator—helped to surmount the difficulties, and the special cultures of fruit, flowers, and vegetables were noteworthy in the annals of gardening fame.

It is worth special notice that the auricula, carnations, tulips, and other flowers were well to the fore, whilst rhubarb and gooseberries were subjects which found favour with exhibitors at that time. Many varieties of these flowers, fruit, and vegetables are cultivated now, and find favour in our gardens, whilst it may also be said that, with the advance of science in horticulture, the hybridist has succeeded in obtaining kinds of better size and quality. Comparing the heating of greenhouses with present-day arrangements, flues were used in all structures, and the lecturer humorously described how he as a boy had to creep up these flues to clean them. One could imagine his appearance upon emerging from this ordeal. Happily for the cultivator, different methods exist now than then.

Diseases in plants years ago almost totally exterminated some kinds; for instance, the hollyhock sunk almost into oblivion through a special disease. Now we have science to help us, so that for nearly all pests a remedy is to be found. Fashions have changed considerably, too, some of them seeking revival now, but many gone never to return. One of the principal successes gained by the lecturer was a prize for melons at the International Flower Show in 1866, and he was proud of the fact that he could compare the great International Show of 1912 with that of 1866. Present-day horticulture is of a very high standard, especially in this country, and his remarks to the young men to each try their utmost to climb to the top of the ladder of fame in the various cultures were received with great enthusiasm.

Mr. Gregory had a good series of slides to illustrate his lecture, and many of the views shown on the screen were copies of the old methods adopted years ago to procure good results, in comparison with views of present-day facilities.

The proposal of a hearty vote of thanks to Mr. Gregory was received with much acclamation, each member present having spent an instructive and enjoyable evening.

Several pleasing exhibits adorned the room. A grand batch of lily of the valley shown by Mr. T. Butcher received keen scrutiny, as also did six pots of freesias staged by Mr. G. Scrivens.

Chester Paxton Society.

At the meeting held on Saturday at the Grosvenor Museum, Mr. John Weaver, of Christleton Hall Gardens, read an interesting and instructive paper on "The Loganberry: Its History, Use, and Culture." Mr. John Wynne, of Rowton, was to have presided, but was prevented through illness, and the duties of chairman were undertaken by Mr. R. Wakefield.

Mr. Weaver traced very clearly the history of the discovery of the loganberry at Santa Cruz, U.S.A., by Judge I. H. Logan, after whom it received its name. The lecturer stated that it was a cross between the "Red Antwerp" raspberry and the Californian wild blackberry "Auginbaugh," which were growing side by side in the Judge's garden; the latter predominated and got mixed in with the raspberry, and the two flowered and fruited together, and were crossed by wind or insects; self-sowed seed produced fruit in 1884. The loganberry was introduced into this country in 1893, and an exhibit by Messrs. Kelway and Son received an Award of Merit of the R.H.S. in 1903. The lecturer gave some interesting details concerning the loganberry, as to yield per acre, keeping properties, time of fruiting, taste, description of canes, leaves, and fruits, its hardiness against frosts, etc. He next spoke from personal experience on cultivation, dealing

NEWS FROM HEADQUARTERS.

PROGRESS.

If our grandparents could see the wonderful activity and development taking place in every department of business life to-day, to put it mildly, they would be astonished.

If Mr. James Carter, the late founder of the seed house of James Carter and Co., could pay a visit to Raynes Park, he would find it difficult to understand that such a great business could have developed in less than three-quarters of a century.

Endeavouring to discover the reason of it, he would be told that "Specialisation" was the keynote to it all.

To the lay mind "to specialise" in relation to seeds means very little, but to those intensely interested in gardening it means much.

Any reader of this article who would like to know what we mean by it will willingly be shown our organisation, but that will necessitate a visit to Carters Seed Establishment at Raynes Park. A hearty welcome is extended to all.

JAMES CARTER and CO.,
Seedsmen to H.M. the King,
Raynes Park,
LONDON, S.W.

with the soil, situation, planting, trailers, and trellises; and gave some good cultural hints. The enemies to the plant were the raspberry beetle, a fungoid disease in the canes, and birds, which would attack the loganberry if short of other fruits. As to its uses, the most important the loganberry was put to was bottling; it was also used for jams, jellies, tarts, wine, and syrup. The lecturer in conclusion mentioned the results of crosses between the loganberry and other berries.

An interesting discussion followed the reading of the paper, those taking part being the hon. secretary (Mr. G. P. Miln), Mr. N. F. Barnes, and the Chairman. The lecturer was accorded a very hearty vote of thanks.

TESTIMONIAL TO MESSRS. ADNITT AND NAUNTON.

The question of a testimonial to Messrs. Adnitt and Naunton, first suggested in these columns, has been taken up vigorously. Two committees have been formed, a Shropshire Committee to deal with the matter locally, and an Exhibitors' Committee, with Sir Harry J. Veitch, V.M.H., as chairman, to deal with wider interests. Mr. N. F. Barnes, Eaton Gardens, Chester, and Mr. W. G. Brazier, the new secretary of the Shrewsbury Fete, are the hon. secretaries, and to them, at The Square, Shrewsbury, subscriptions should be sent. It is of more than passing interest to notice that representatives of the GARDENERS' MAGAZINE, and the three other horticultural journals which have reported the Shrewsbury Show for so many years, have a place on the committee. The following letter is being sent out by the Committee:

"The recent resignation of Messrs. Adnitt and Naunton, after a period of 38 years of unbroken and gratuitous service, demands some tangible recognition, not only from the members of the Society itself, but from that far wider section of the community, which includes exhibitors, judges, horticulturists, and all those who are interested in any degree in the culture of flowers, fruits, and vegetables.

"The undoubted success of the annual shows has been due in a great measure to the indefatigable exertions and the unvarying kindness and courtesy of Messrs. Adnitt and Naunton to exhibitors and all others connected with the undertaking. A taste for horticultural pursuits has thus been engendered and fostered amongst the many thousands of visitors, who have annually attended the Society's exhibitions.

"Messrs. Adnitt and Naunton were amongst the original promoters of the Society in 1875, and from an unpretentious beginning, it has gone on from year to year with a record of unqualified successes, until it has now attained a pre-eminent position in the world of horticulture.

"As instancing the esteem in which these gentlemen are held by the leading horticulturists of this country, it may be mentioned that the Royal Horticultural Society has conferred upon them the greatest honour in its power, viz., the Honorary Life Fellowship of the Society.

"A very rare honour has also been paid them by the presentation to each of the Veitch Memorial Medal.

"A fund has been initiated with a view of presenting both gentlemen with a testimonial, and the Committee hope to be allowed to add your name to the list of subscribers.

Yours faithfully,

N. F. BARNES,
W. G. BRAZIER.
Hon. Secs."

GARDENING ENGAGEMENT.

Mr. George H. Emmett, foreman to Mr. Coomber at The Hendre Gardens, Monmouth, and previously at Mentmore and Rolleston Hall, has been appointed head gardener to F. Martin, Esq., The Lindors, St. Briavels, Gloucester.

THE NURSERIES, CHISLEHURST, KENT.

It is but just over four years since Messrs. Whitelegg and Page started their nursery business at Chislehurst, but such is the energy and enthusiasm of the two members of the firm that they have already built up a flourishing business, and have their nursery well stocked with a most interesting collection of choice, useful, hardy plants for both border and rock garden. Indeed, a visit to the Chislehurst nurseries, even thus early in the year, is calculated to prove enjoyable, and profitable to anyone who takes an active interest in hardy plants. It has from the outset been a policy of the firm—and a wise policy—to keep a keen look out for new and distinct varieties of popular classes of plants, and the result is that, whether it be phloxes, Michaelmas daisies, delphiniums, or pentstemons for the borders, or saxifrages, aubrietias, or primulas for the rockery, the latest introductions and most attractive varieties in cultivation are to be found at Chislehurst.

That most effective Geum coccineum Mrs. J. Bradshaw is one of Messrs. Whitelegg and Page's introductions, and it has obtained so high a degree of popularity that it is scarcely necessary to describe its particular merits and value as a border plant, or even as a subject for bedding. As might be expected, there is a very big stock of this plant at the nurseries, despite the fact that many thousands have already been sold. It will interest readers to learn that a bright yellow geum is coming along, which the firm consider will equal Mrs. Bradshow in vigour of growth, size of bloom, and freedom of flowering, and, being of a rich shade of yellow, will be a most delightful plant for growing in bold clumps.

In a representative collection of aubrietias, Violet Queen stands out prominently, being as distinct in foliage and habit as it is bright and attractive in the colour of its flowers. One is almost prepared to say we have in Violet Queen attained very nearly the ideal aubrietia, and we imagine but few collections of rock plants will long be without it. The number of pentstemons that have secured the distinction of an Award of Merit from the Royal Horticultural Society is very small, but the brilliant flowers of Gaddesden Gem raised by Mr. Gentle, and shown last year, succeeded in gaining for the variety the Award which, need it be said, it thoroughly deserved. Messrs. Whitelegg and Page have now the entire stock of this charming pentstemon, which doubtless will become a great favourite. It may be mentioned that Southgate Gem, another pentstemon which is now met with very frequently, is of Mr. Whitelegg's raising, and it has strong claims to being regarded as one of our most useful bedding plants.

A quite new race of brightly coloured mossy saxifrages has sprung up of late years, and with characteristic foresight Messrs. Whitelegg and Page lost no time in forming a collection of all the best of them. Some twenty varieties of the mossy section are catalogued by the firm, the cream of the set being Red Admiral, Pencilled Beauty, Bathoniensis, and Arkwrighti. It is good to know the firm realise that while it is desirable to stock varieties that are decided advances, a severe check must be put upon the tendency to unduly increase the number of named varieties, especially when the differences between them are so slight that identification is almost impossible. The same fault threatens the heucheras, named varieties of which have cropped up in numbers of late. A few of these are crtainly fine, but nobody wants a couple of dozen varieties of Heuchera sanguinea, which might sufficiently be described as selected forms of H. sanguinea superba.

Among the primulas at Chislehurst one finds practically all the latest introductions from China and the Himalayas. There are fine batches of P. Littoniana, P. Veitchi, P. Winteri, and P. pulverulenta, whilst such old favourites as P. japonica and P. cashmeriana are well grown in big batches. Iberis sempervirens var. Perfection is in Mr. Whitelegg's opinion the best of the perennial candytufts, and, in consequence, it is grown in large batches, as also is Nepeta Messina superba, a variety of far neater habit and superior colour to the ordinary type. Among aquilegias the charming variety Mrs. M. Nicholls is singled out for special favour, and truly it deserves it. The large, long-spurred flowers are extremely beautiful, and it is not surprising this plant is in brisk demand. The recently-introduced Wahlenbergia vincæflora has already found a place in the Chislehurst collection, and so also has the bright yellow form of Viola gracilis. The rich purple V. gracilis is largely grown, and is in increasing demand.

The bedding violas occupy much space, the collection embracing most of the up-to-date varieties. Mrs. G. G. Whitelegg is a splendid rayless yellow that can be well recommended. Throughout the nursery the same principle prevails of selecting the very choicest varieties of a family of plants, and thus we find the collections of delphiniums, phloxes—herbaceous and alpine, early chrysanthemums, pæonies, and, in fact, all kinds of plants, which are really judicious selections from the host of varieties that may be met with in all quarters of the country.

Although hardy plants are the leading speciality of the firm, there is a good range of glass on the nursery, and one of the most attractive features of the indoor department at the time of my visit was a splendid collection of Primula obconica hybrids. These range in colour from pure white to rich crimson, and there are also some pleasing lavender and blue shades.

Quite apart from all else in the nursery is the Newberry, one of the blackberry-loganberry achievements, which may certainly be described as a useful, attractive, and quite distinct fruit that is well worth growing.

That the firm's business is making satisfactory progress is evidenced by the fact that they have already found it necessary to extend their operations. A branch nursery of considerable area has been opened at Orpington, and here the bulk of the herbaceous border plants are produced. A comprehensive collection of roses is another feature at the Orpington Nursery, and there are also bush and tree fruits, forest and ornamental trees, privet and other hedging plants, and a fine lot of climbing plants for walls, arches, and trellis work. Seed-saving of choice novelties is undertaken, and an extensive cut-flower trade is done.

Landscape gardening is an important branch of the business, a staff of expert workmen being kept constantly busy with the contracts secured for laying out, remodelling, or extending gardens in various parts of the country.

VISITOR.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

DICTIONARY OF PLANT NAMES.—F. J., Hampstead: Will you please recommend me one or two books giving plant names, but not cultural notes, and say where they can be obtained?—We do not know a single dictionary of plant names that has appeared in modern times without cultural notes, however brief. "Johnson's Gardener's Dictionary" (G. Bell and Sons) contains a very large number of plant names, with brief descriptions of the species listed, and a quite short cultural note for each genus. The Kew Hand Lists contain nothing but plant names and habit, and a list of these handbooks and prices can be obtained on application to the Curator, Royal Gardens, Kew. If you have not the "Encyclopædia of Gardening" (W. H. and L. Collingridge, 148, Aldersgate Street, E.C., post free, 3s. 10d.), it will be worth your while to add it to your library as it contains selections of species and varieties and a fund of other horticultural information.

GERMINATION OF VEGETABLE SEEDS.—F. G. S., Walton-on-the-Naze: I shall be greatly obliged if you will tell me the average time required for the seeds of the commoner kitchen garden crops to germinate under fair conditions of soil and climate.—Radish germinates in from 3 to 6 days; turnip, 4 to 8 days; beans, cabbage, cauliflower, and endive, 5 to 10 days; lettuce, 6 to 8 days; cucumbers and peas, 6 to 10 days; tomatoes, 6 to 12 days; beet and onions, 7 to 10 days; salsify, 7 to 12 days; celery and parsnip, 10 to 20 days; and carrot, 12 to 18 days.

PLANTS FOR A COOL GREENHOUSE.—W. B. S., Swindon.—Will you kindly give a selection of plants for a cool greenhouse, as follows: Six flowering plants, rather out of the way kinds, other than florist's flowers, azaleas, geraniums, etc.; six foliage plants, uncommon sorts, other than coleus, Rex begonias, and aspidistras; six climbers, other than cobæas, asparagus, smilax, clematis, and roses. They must all be of fairly easy culture and readily propagated from seeds.—We should have been better able to render assistance had we known the minimum winter temperature of the greenhouse. Flowering plants not very widely grown for greenhouse decoration are Lobelia tenuior, 9 to 12ins., blue, white, or rose, annual; Alonsoa Warscewiczi, 15ins., scarlet, annual; double balsams, 18in., various, annual; Calceolaria Clibrani, 2½ft., yellow; Calceolaria Veitchi, 3ft., white; Celsia arcturus, 18in., clear yellow; Datura cornucopia, 18ins., white, marked purple; Impatiens Holsti, 2ft., rose-pink; Nicotiana Sanderæ, 3ft., rose; Rehmannia angulata, 3ft., pink; Trachelium cœruleum, 18ins., bluish-mauve; Torenia Fournieri, 1ft., blue and white; and T. Bailloni, yellow and purple. There are many others, and we have given more than six so as to leave room for the exercise of taste in form, habit, and colouring. For foliage plants easily raised from seeds there are the amaranthus, particularly A. tricolor splendens, and A. salicifolia, Cyperus natalensis, Eulalia japonica variegata, variegated maize, Melianthus major, and Ricinus Gibsoni. Good climbers for the greenhouse are Maurandya Barclayana, purple; Mina lobata, red and orange; Ipomæa rubro-cœrulea, sky-blue; Abutilon megapotamicum, yellow and scarlet; Kennedya coccinea, scarlet; and Tropæolum Lobbianum, orange.

ORIGIN OF POLYANTHUSES.—A. C., Yarmouth, I. of W.: My polyanthuses are coming into bloom finely just now, and I have been wondering how these beautiful spring flowers originated. Can you tell me whether they are of hybrid origin, or of pure descent from one species?—Garden polyanthuses have been evolved by years of patient care and selection from Primula variabilis, itself a hybrid between a form of the common primrose (P. vulgaris) and the cowslip (P. officinalis). Rigid selection and high cultivation have combined to produce a very vigorous race in which there is a wide colour range.

OVERHANGING TREES.—R. W. B., Northampton: My neighbour is evidently very partial to trees of large growth, for some years ago he planted rather freely in his garden such kinds as limes, sycamores, and elms. As will be readily understood, a considerable proportion of them occupy positions on the boundaries. Several of these trees have attained a size that renders them a nuisance to me, for their branches hang over my garden, and greatly interfere with the growth of the various kinds of hardy herbaceous plants with which the borders are planted. I shall be greatly obliged by your advising me what I can do to prevent further injury.—The right of owners of gardens that are being injured by the overhanging branches of trees which are growing outside the boundaries is well defined. He can cut back the branches of the trees in a line with the boundary fence, but not beyond that. Instead of doing this without first communicating with the owner of the trees we would advise you to call upon him, and in a friendly manner explain to him the injury that is being done to your garden. If this fails, give him formal notice that you shall cut back the branches in a line with the fence unless he prunes them within a certain date. You must not prune any of the branches that do not hang over the fence.

TECOMA RADICANS.—S. E. J., Abergavenny: I have seen Tecoma radicans grown in another part of the county as a greenhouse plant, but quite recently I was told the species was hardy. Please tell me whether I was rightly informed, and whether you think this fine climber would succeed on a south wall.—Tecoma radicans is only hardy in favoured localities and in the South. It should succeed at Abergavenny if planted against a wall having a south exposure, and where there is also some shelter from cold and cutting winds.

JAPANESE DWARFED TREES.—Dufftown, Wimbledon: May I ask your assistance in the following matter? I received to-day four Japanese dwarfed trees, sent us as a present from Japan. The names on the labels are Carpinus yedoensis (beech), Tsuga Sieboldi (yew), Zelkowa Keaki (elm), and Quercus dentata (oak). I should be grateful for directions as to their cultivation. The oak has made a lot of soft growths, some of which are partly mildewed; should they be cut off? The plants were packed in moss, and so a good deal of soil has been shaken from the roots, leaving insufficient to fill the pots sent. What material should I use for potting, and have I done right in placing the plants in a greenhouse that is kept at 45 deg. during winter? The beech is rather large, so should I plant it in a border?—Carpinus yedoensis we do not know, but if the generic title is correct it is a hornbeam, not a beech; Tsuga Sieboldi is not a yew, but a coniferous tree closely allied to the abies; Zelkowa Keaki is more correctly Zelkova acuminata, and a very close relative of the elms; Quercus dentata is probably a form of Q. Cerris, the Turkey Oak. Pot them all firmly in good loam of a very fibrous character, and keep them in the greenhouse until rooted, and recovered from the journey, but lightly shade them from sunshine and afford ample ventilation—a cold frame, if deep enough, would provide sufficient shelter. During the summer stand the plants out of doors, and see that they do not lack moisture. In the case of the oak, most likely the soft growths made on the journey will prove useless, therefore in a few weeks' time, when new roots have been made, shorten the branches back to prominent buds, or to where new, clean growths may have already started. In the case of the hornbeam, if you plant it out it will quickly lose its dwarfed appearance. You had, therefore, better pot it; pinch out the growing points occasionally to prevent any great extension of branches.

NAMES OF PLANTS.

W. H., High Wycombe.—Saxifraga crassifolia.

R. B .B., Sevenoaks.—1, Ribes sanguinea; 2, Saxifraga apiculata; 3, Rhododendron Præcox.

G. B. C., Saffron Walden.—1, Abies Douglasi; 2, Cyperus alternifolius; 3, Habrothamnus elegans.

L. F., Rugby.—1, Tradescantia zebrina; 2, Fittonia Pearcei; 3, Nepenthes Mastersiana; 4, Oncidium concolor.

H. S., Worcester.—1, Mussænda frondosa; 2, Saccolabium bigibbum; 3, Galax aphylla; 4, Dendrobium nobile; 5, D. Wardianum; 6, Eucalyptus citriodora.

THE NURSERY TRADE AND UNDEVELOPED LAND DUTY.

At a meeting of the Horticultural Advisory Committee of the Land Union, a discussion took place on the Referee's decision in the case (which was brought by the Land Union on behalf of its members, Messrs. Geo. Jackman and Son), of George Jackman and Son v. The Commissioners of Inland Revenue, in which it was decided that Messrs. Geo. Jackman and Son were liable for Undeveloped Land Duty in respect of land used by them in their business as nurserymen. Subsequent thereto the following resolution was passed:—

"The Nurserymen and Seedsmen comprising the Horticultural Committee of the Land Union desire on behalf of the trade to call attention to the hardship imposed on their industry by the present state of the Law in respect of the Undeveloped Land Duty as disclosed in the recent case of Jackman and Son v. The Commissioners of Inland Revenue. They urge that at least so much of their land as is necessarily used as an adjunct to Glass Houses should be exempted from Duty (on the same basis as the site of the Glass Houses themselves, is exempt), and they are of opinion that the minimum amount required is in the proportion of 5 to 10 acres of land for each acre of glass. At the same time, they desire to point out that the Duty is in itself unfair to their trade, as it represents an annual fine for using their land for the purpose of horticulture, although every other trade is wholly exempt under all circumstances, and in spite of the fact that some of the trades so favoured employ much less capital and labour in proportion to the land occupied."

OBITUARY.

LORD TREDEGAR.

We learn with regret of the death of Viscount Tredegar, which took place at Tredegar Park, Newport, Mon. Lord Tredegar was one of the few survivors of the Light Brigade that made the famous charge at Balaclava. He was a large landowner, a great farmer, and a keen gardener. Both Newport and Cardiff have reason to keep his memory green, as both towns have received from him many benefactions, including parks, sites for churches, etc. To the University College, Cardiff, Lord Tredegar gave in princely fashion.

CANARY GUANO

FOR GARDEN AND GREENHOUSE.

There is no Fertilizer equal to Canary Guano for the Garden and Greenhouse. Compare its results, its analysis, and its fine condition with any others, and you will be convinced of this. Canary Guano immensely improves the colour and size of all Flowers, and doubles the yield of all Fruit and Vegetables. It is particularly suited to lawns, golf greens, and cricket grounds. Canary Guano is manufactured by The Chemical Union, Ltd, in conjunction with their associated company, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, who are the largest Special Fertilizer Manufacturers, and whose goods are used all over the World.

CANARY GUANO is sold by Seedsmen, etc., in tins and bags, from **6d.** to **20s.**

"CARNATIONS, PICOTEES, AND PINKS" will tell you plainly how to grow these favourite flowers to perfection. The work is freely illustrated with plates of leading varieties, and explanatory diagrams. Price 2s. 6d. net by post, in box, 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

FORTHCOMING ENGAGEMENTS

TUESDAY, March 18.—Royal Horticultural Society; Narcissus Committee meets at 11.30 a.m.; Fruit, Vegetable, and Floral Committees at 12 o'clock; Lecture at 3 p.m. on "The Romance of Weeds," by Mr. R. Lloyd Praeger, B.A.; Scientific Committee at 4 o'clock.
SATURDAY, March 29.—Paisley Spring Show.
TUESDAY, April 1.—Royal Horticultural Society; Narcissus and Tulip Committee meets at 11.30 a.m.; Fruit, Floral, and Orchid Committees at 12 o'clock; Lecture at 3 p.m. on "The Literature of the Rose," by Mr. Arthur W. Paul; Scientific Committee at 4 o'clock.
Horticultural Club, Monthly Dinner and Conversazione at the Hotel Windsor, 6 p.m.
Scottish Horticultural Association.
National Amateur Gardeners' Association.
WEDNESDAY, April 2.—Royal Horticultural Society's General Examination in Horticulture.
Liverpool Spring Show; two days.
THURSDAY, April 3.—Huntingdon Daffodil Show.
Linnean Society meeting.
SATURDAY, April 5.—French Horticultural Society of London.
New York International Horticultural Exhibition; eight days.
TUESDAY, April 8.—Cornwall Spring Show at Truro; two days.
Devon Spring Show at Barnstaple; two days.
WEDNESDAY, April 9.—Edinburgh Spring Show; two days.
Tewkesbury Daffodil Show.
THURSDAY, April 10. — Perpetual Flowering Society's Provincial Show at Leamington; two days.

FORTHCOMING EVENTS.

Epsom Horticultural Society; Rose Show, June 30, at Woodcote Grove; Summer Show, August 4, at Epsom College.
Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.
Ealing Horticultural Society, July 9.
Weybridge Horticultural Society, July 10, at Barham Lodge, Oatlands Drive.
Ulverston Rose and Sweet Pea Show, July 18.
Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.
Tunbridge Wells Flower Show, July 23 and 24.
St. Quintin Horticultural Society, July 24, in the Gun Club grounds, Wood Lane, W.
City of London Rose Show, July 26, at Cannon Street Hotel.
Worth Horticultural Society, July 30.
Datchet Horticultural Society, August 4, at The Lawn.

CATALOGUES RECEIVED.

J. CHEAL AND SONS, LIM., CRAWLEY, SUSSEX.—As a reminder that the planting season is not yet over, we have received a catalogue of trees, shrubs, roses, topiary work, etc., from the Crawley firm.

THOMAS S. WARE, LIM., FELTHAM.—Ware's Begonias enjoy a high reputation, and the new catalogue of these plants shows that progress continues. The leading varieties are fully described, and many of the novelties are illustrated.

H. J. JONES, LIM., HITHER GREEN, LEWISHAM.—The Ryecroft specialities, i.e., chrysanthemums, Michaelmas daisies, and perennial phloxes, practically fill the handy catalogue before us. It will be remembered that this firm's fine collection of phloxes at Holland Park Show in 1912 was purchased for Kew.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Evesham Custom.

For some considerable period it has been well known to those who take an active interest in the commercial aspects of horticulture that one of the chief centres of the market garden industry in England is that which has been established during the past half-century in the Vale of Evesham. About forty years ago the area around Evesham under fruits and vegetables grown for market was 1,000 acres, but, according to Mr. Raymond Webb, whose paper on the "Evesham Custom," read at the recent meeting of the Farmers' Club, has evoked widespread interest, it now exceeds 10,000 acres. The remarkable development which market-gardening has undergone, more particularly of late years, in the Evesham district, has been for some time past a matter of much surprise to those who are not well acquainted with the climatic and soil conditions that obtain, but it admits of a ready explanation. The soil is, for the most part, highly fertile and readily worked, and the climate is so genial that growth is comparatively rapid, and the growers are able to market their produce at an earlier period than is possible in some districts farther south, a point of much importance in the case of crops that are marketed during the spring months. These are not the only advantages enjoyed by the growers in the Vale of Evesham. They are within a comparatively easy distance of the majority of the chief populous centres, and the railway facilities are such as to enable them to market their produce expeditiously, and in the best possible condition. It must also be stated that those who are engaged in the industry are remarkable for their industry and business ability, and also for their capacity for sustained effort, as evidenced by the long hours they work during the busy seasons. The majority of the growers, many of whom are now prosperous, began life as labourers, and commenced business on their own behalf, according to Mr. Raymond Webb, with a small area of unplanted land, usually about an acre in extent, which they cultivated early in the morning and in the evening, with an occasional day off from their usual work. In course of time the land was thoroughly cleaned, and planted with the various kinds of fruits that thrive in the district, and such vegetable crops as are found to be the most profitable. When the land began to bring in a steady income, and the growers had saved a little money, they gave up working for others, and rented another piece of newly-laid-out land, "or more often," to quote from Mr. Webb, "bargained with a neighbour for the tenant-right of a holding adjoining or near to their own." Besides

MR. RALPH HALL.

the growers who thus progressed with small beginnings, the sons of the prosperous market gardeners have engaged in business on their own account, and gentlemen's sons with capital have turned their attention to market gardening, and these, in most cases, commenced on established holdings, having purchased the tenant-right by direct bargaining with the owners. Thus has grown up the "Evesham Custom," which Mr. Webb describes as "a system of land tenure based on practically fixed rents and free sale, which has given that security without which the development of the district would not have been possible." Under this custom a tenant who wishes to dispose of his interest in a market garden holding finds his own incoming tenant, and arranges the terms for tenant-right with him direct. The landlord is not concerned with the question of compensation, but he has the option of refusing to accept the incoming tenant. Should the landlord refuse to accept the tenant submitted to him, the case is quite exceptional where the outgoing tenant has any difficulty in finding another who is acceptable to the landlord. Should all the incoming tenants that are introduced fail in obtaining acceptance, the only course open to the tenant is to serve the landlord with a notice to quit, and to claim such compensation as is legally due to him from the landlord direct at the termination of the tenancy. This, however, is a rare occurrence, for tenants are seldom refused unless they are known to be indifferent cultivators, or bad rent-payers. Professional valuers are seldom required to act between the tenants, as the amount to be paid for tenant-right is determining by bargaining in the same manner as would be adopted in the purchase and sale of produce. One of the best points of the custom is, Mr. Webb considers, the facility with which a tenant can realise the value of the tenant-right at any season of the year, as the majority of the landlords allow the transfer to be made although the tenancies are determinable by notice to quit, usually at Michaelmas. If a grower, for any reason, wishes to realise the tenant-right of a part or the whole of his holding he can usually do so in a very short time, often in the course of a few hours. This system of transfer is said to work well in practice, for it tends to maintain market garden land in a high state of cultivation, because a transfer usually takes place in such a short time that there is no opportunity for allowing the land to deteriorate. With reference to the landlord's point of view, Mr. Webb states that the system of transferring from tenant to tenant is satisfactory. It relieves him of the liability to compensate the tenant directly unless he requires the possession of the land for his own purpose. It further saves him the anxiety and expense attendant upon a valuation, and it saves him from the risk of having to pay for the tenant-right at a higher rate than he may be able to obtain from the new tenant. The compensation of occupants of land devoted to the cultivation of fruits and vegetables for market for the improvements that have been made is a difficult matter when the amount is determinable by valuation, and,

in many instances, gives rise to much friction. It is, therefore, gratifying to have such evidence as that which Mr. Raymond Webb has produced of the satisfactory manner in which the "Evesham Custom" has worked, especially as it confirms the view that it should have a much wider application.

Mr. Ralph Hall, who for the past 14 years has had charge of the gardens at Penninghame House, Wigtownshire, is a Northumbrian by birth. At Alnwick Castle he commenced his gardening career under Mr. Harris, with whom he stayed eight years, first as an apprentice, and later as journeyman in the various departments of this ducal establishment. From here he was transferred to Lowther Castle, then in charge of Mr. Clarke, as inside journeyman, and a year afterwards was promoted to foreman's position. Lowther, then as now, was renowned for its extensive flower gardens, in which, beside the bountiful seasonable embellishments, rock and Alpine plants were given a prominence that at the time proved a surprise and delight to many. Leaving Lowther Castle at the end of two years, Mr. Hall spent a short time in the nurseries of Messrs. James Backhouse and Son, of York, from whence in due course he was recommended as outside foreman to Mr. Street, at Floors Castle, Kelso, which position he held for three years. At Floors, it is perhaps unnecessary to say, gardening is carried out on a very comprehensive scale, and upon the most approved lines. With the experience thus gained in these three large and notable establishments, Mr. Hall entered upon his duties at Penninghame House, at that time in the occupancy of the late Mrs. Maxwell Blair, but now tenanted by J. W. Oxley, Esq. During his term of service here Mr. Hall has done much to improve the place, drives and walks having been opened up, and broad stretches of lawn laid out in the vicinity of the mansion, while the extensive planting of roses and herbaceous plants, and shrubs and trees for utility and spectacular effect, has received much attention. During the two past seasons renovation of the hardy fruit quarters has been in progress, many old trees, particularly those of the apple and pear, having been removed and replaced by others more in accordance with the possibilities and requirements of the present time. As an exhibitor Mr. Hall has given a good account of his abilities for many years past, and a fair share of the principal awards offered at county and other exhibitions have fallen to his prowess, more particularly in the fruit classes, for pot plants, and table decorations. The shallow soil, and liability of the situation to late spring frosts have had a rather adverse influence upon his efforts in the cultivation of prize vegetables in a district where, in more congenial sites, these are remarkably well grown.

The Hardy Plant Industry now occupies so important a position among the various branches of commercial horticulture that we shall in our next issue (March 29) publish a freely-illustrated article dealing with this interesting phase of horticultural activity. This will contain a sketch of the historical aspects of the flower garden in the United Kingdom during the past sixty years, and deal at length with the development of the taste for hardy plants, the immense improvements that have been effected in the more important kinds, and the enormous extension their cultivation in commercial establishments has undergone within the past four decades. The illustrations accompanying the article have been selected with special reference to their value as examples of the successful use of herbaceous and alpine plants and aquatics, and other moisture-loving plants in beautifying the flower garden. There will also be illustrated articles on alpine plants of recent introduction, delphiniums, gladioli, and pentstemons. As the issue will have a largely-increased circulation, we strongly advise those of our readers who require additional copies to give their orders early.

Birmingham Daffodil Show.—Mr. Herbert Smith, the secretary of the Midland Daffodil Society, writes: "We have just discussed the final arrangements for our coming Daffodil Show, and, on account of the Royal visit to Birmingham, which falls on April 23 (the date we had originally fixed for opening our show), we have decided to hold our exhibition a day earlier, therefore it will be held on April 22 and 23, instead of on April 23 and 24, as previously arranged. A notification of this alteration of date will be greatly appreciated."

Mazus rugosus.—With reference to this interesting plant, for which the Wargrave Plant Farm, Lim., were granted an Award of Merit at the meeting of the Royal Horticultural Society on March 4, Mr. B. Crisp writes: "We have much pleasure in sending you the following particulars respecting Mazus rugosus, as there appears to be some doubt existing as to whether it is a perennial. The plant originally came from the Himalayas, and spreads by means of procumbent stems, which root as they grow, and produce flowers one inch in height. The fact that each rooted stem had a flower when exhibited seems to have given the impression to many people that it was a pan of seedlings. When established it literally covers itself with flowers during the early spring months, also producing a few solitary flowers during the summer, which are of a deep mauve colour, freely spotted orange on a white ground. The plant is undoubtedly perennial. Johnson's Gardeners' Dictionary, 1868, describes both Mazus rugosus and Mazus pumilo as hardy annuals, but there can be no doubt that this description is erroneous. Respecting Mazus pumilo, this is a quite distinct plant; it produces slender underground rhizomes, and the leaves are spathulate, with slightly waved edges, which are about one inch long, and only produces its flowers during the summer months, whereas Mazus rugosus, as we have before stated, flowers during the early spring and summer months. As to the date of introduction we are not quite sure." We gave a characteristic illustration of this charming plant in our issue of March 8.

National Diploma in Horticulture.—The committee appointed by the Royal Horticultural Society, in co-operation with the Board of Agriculture, Horticulture, and Fisheries, met for the first time on Thursday, March 13. A question at once arose, "What is Horticulture?" which was answered as follows: "Horticulture is a definite craft of itself, and not a department of agriculture. Horticulture as differentiated from agriculture includes the more intensive cultivation (as usually practised in gardens) of fruit, vegetables, flowers, shrubs, and ornamental trees." The committee formulated the following statements: (1.) "In view of the acknowledged demand on the part of horticulturists for an official recognition of professional ability, the Royal Horticultural Society, acting in co-operation with the Board of Agriculture, has decided to establish a National Diploma in Horticulture, and a jointly-appointed committee has been asked to formulate a scheme." (2.) "Among those for whose benefit the diploma is established are the following (in alphabetical order): Florists, fruit growers, gardeners, horticultural inspectors, horticultural instructors, market gardeners, nurserymen, public park gardeners, and seedsmen." (3.) "The diploma will be available for men and women on equal terms." Information as to the qualification of candidates, the method of examination, and the subjects of the syllabus, will be published as soon as determined upon. Prospective candidates are requested not to make inquiries of the secretary until such further publication has taken place.

Seed Potatoes.—In the report issued by the East Anglian Institute of Agriculture, Chelmsford, on the field trials conducted in 1912, it is stated that the value of the change of seed was demonstrated in a striking manner, the crops obtained from Irish and Scotch seed being almost double those from seed grown locally. Seed from Lincolnshire, although not so good as Irish and Scotch seed, was distinctly superior to that from Essex. Seed from Scotland which had been grown one year locally was found to be markedly inferior to seed obtained directly from Scotland in the case of each of six varieties which were so tested. With reference to the most suitable size of tuber for planting, it is reported that large seed, consisting of the smaller tubers from the "ware," gave a better crop than small tubers of the ordinary seed size.

Horticultural Research.—The scheme for the promotion of research and the provision of technical advice for agriculturists and horticulturists in England, in respect of which the Treasury sanctioned a large annual grant, has been in operation several months, and now definite arrangements have been made with a number of institutions which have undertaken to carry out the scheme. The objects aimed at are to aid research in certain definite groups of subjects, and the concentration at one institution, or at institutions working in combination, of the scientific work in each group. The institutions and the subjects selected include plant physiology, Imperial College of Science, South Kensington; plant breeding, Cambridge University and John Innes Institution, Merton, Surrey; plant pathology, Royal Botanic Gardens, Kew; fruit growing, including the practical treatment of plant diseases, Bristol University, in conjunction with the National Fruit and Cider Institute; plant nutrition and soil problems, Rothamsted Experimental Station, Harpenden, Herts. In addition to research work, in fruit growing, to be carried out at Bristol University, arrangements have, as we have already announced, been made for establishing an experimental fruit station in Kent, which will be under the supervision of the South-Eastern Agricultural College, Wye, Kent.

Horticultural Club.—The report of the Horticultural Club for the past year forms a neat brochure, and is of much interest. It contains, as a matter of course, the report and balance-sheet for 1912, and summaries of the lectures given at the house dinners during the year, and a list of members which is of much greater length than that contained in any previous report. The lecture by Mr. H. R. Darlington on "The Rose as a Flowering Shrub" is given in full, and will be found of much interest by those who appreciate the distinctive characteristics of the more beautiful of the roses having specific rank.

Flowers from the Scilly Isles.—The supplies of narcissi flowers from the Scilly Isles are much smaller than for many years past, and the returns to the growers can hardly prove satisfactory. Owing to the excessively wet weather experienced during the summer the bulbs failed to ripen properly, and many decayed in the soil, hence the shortage in the flowers at the present season.

Importation of American-raised Fruits.—It is reported that one of the most recent of the developments in English fruit farming is the importation from America of trees of the fruits raised by Mr. Luther Burbank, who produced the edible cactus for the use of cattle in the desert, and other new varieties of plants. Scions, or lengths of new wood, for grafting are imported in large numbers, and many new varieties of fruits are being imported by Messrs. Chivers and Sons, fruit growers and preservers, of Histon, Cambridge, for the purpose of comparing these new fruits with the standard varieties of English growth.

French Horticultural Society of London.—The anniversary dinner of this society, which has now reached its twenty-fourth year, will take place on Saturday, April 24, at the Café Royal, 68, Regent's Street, at 6.30 p.m. Mr. P. Rudolph Barr will preside, and those who are desirous of being present can obtain tickets (6s. each) and all particulars of the society, and the excellent work it is doing on behalf of young gardeners, from the president, Mr. George Schneider, 11, Great Newport Street, London, W.C.

The National Chrysanthemum Society continues the even tenour of its way. The schedule of prizes and list of members for 1913 is before us, and we find that there will be an early autumn show at the Crystal Palace on October 1 and 2; the great show at the same place, on November 5, 6, and 7; and a late exhibition at Essex Hall, Strand, W.C., on Wednesday, December 10. On this latter date a conference will be held, when papers will be read as follows: "The Evolution and Development of Outdoor Chrysanthemums," by Mr. Norman Davis; and "Chrysanthemums for Outdoor Decoration," by Mr. Thomas Bevan.

HARDY FERNS.

As it is in March that our native ferns commence, like most other vegetation, to resume the actively growing disposition which has lain dormant since the previous autumn, and since they are far more easily handled now than when in full foliage, there is no better time than the present to plant, divide, and replant, pot and repot, or deal generally with them to secure their well-being in the coming season.

Most of them, all indeed of the deciduous persuasion, like the lady ferns, most of the buckler ferns, and others are now represented by mere frondless stumps; while the evergreen species, hartstongues, shield ferns, spleenworts, and blechnums bear more or less damaged and discoloured fronds, which are destined very shortly to be replaced by new sets, and therefore a little damage by the processes above alluded to only constitutes temporary disfigurement. It is, however, not advisable to remove the old fronds, which are still green and full of sap, as there is no doubt that so long as this state exists the still active chlorophyll assists in some measure in stimulating the formation of the new root system, which

PRIMULA PURDOMI.

A distinct Chinese species, the flowers rose-lilac. F.C.C., R.H.S., March 18. Messrs. J. Veitch and Sons, Chelsea.

springs from the bases of the new fronds, and is the main factor in establishing the new growth.

The old fronds, too, if the plants be in the open, play a protective part to the crowns, which under natural conditions are swathed or buried in the debris of previous growths. If we lift up such debris, and examine the crowns of the ferns, we shall find a multitude of new roots, with delicate, whitish feeding points, creeping down from close to the growing points in which the new fronds are coiled up, and until these have reached the soil and penetrated it, exposure to drying winds may seriously damage them, and materially check the growth for the season.

In planting, the habit of growth must be considered. Ferns fall roughly into two main categories, viz., those which form definite crowns, whence the fronds rise more or less on shuttlecock lines, and those which have creeping rootstocks, whence the fronds spring singly. The first class is typified by the lastreas or buckler ferns, of which the common male fern is the more familiar example; and the second by the common polypody, which grows on old walls and in hedges. A third type is a somewhat intermediate one, exemplified in the spleenworts, which form tufts. The shuttlecock class are the boldest growers, with the exception of the royal fern and the bracken, which have these special peculiarities, the former developing a great rootstock covered with short aerial roots, whence the sometimes immense fronds arise in close association on "clump" lines, while the bracken has long, deeply-pentrating, travelling rootstocks or rhizomes, which send up huge fronds at long intervals, and in such a fashion that it is almost an impossibility to transplant it.

To return to the shuttlecocks, these are very apt to imitate the clump formers by producing young plants from the sides of the old ones by means of buds, and these in time become as large as the parent, and by competition tend to check its growth, so that in time a bush is formed. On examination, however, it is found that the clump is nevertheless made up of independent members, so that if the plant be lifted each one can be separated, and will have its own independent roots and frond-system, thus permitting of easy propagation. With some, too, such as the lady fern, this shuttlecock growth in time will develop two or more centres, which gradually grow apart, and eventually, when a decided neck is produced, can be severed by a shallow cut in the depression between them, and then, if carefully forced asunder, each will come away with its own roots, as with the lastreas above described. All that is then needed is to plant or pot the divisions with the crowns just above the soil surface, but not buried.

The creeping ferns, such as the polypodies, can be propagated by severing portions of the creeping rootstocks bearing a frond or two and a growing point, and planting this shallowly, when it will soon establish itself and form an independent plant. As regards soil, a rather lumpy, open compost of loam and leaf mould practically suits all the species usually cultivated, and in pots it is well to provide plenty of drainage so as to avoid sourness by stagnation, which, fond as ferns are of moist conditions, is likely to be fatal.

So much for general treatment. We cannot, however, take leave of the subject without pointing out the practical foolishness of devoting such care to what all those who really know our native hardy ferns regard as mere weeds—i.e., the common forms, which are obtainable for a few pence from the hawkers, or even from many nurserymen. Nature has endowed these weed forms with a capacity of sporting into far more beautiful ones, tasselled, and frilled, and fringed, and beautifully divided on extra feathery lines. Such forms, of which there are hundreds, are catalogued by the trade, who make a speciality of them. Most of them cost but little, and we cannot too strongly advise those who grow ferns to send an order for a few dozen, ignoring the bugbear of long names, and simply saying: "Good tasselled and frilled varieties of the lastreas, hartstongues, lady ferns, shield ferns, and polypodies," and leaving selection to the seller. They will then surely appreciate the benefit of growing varieties, instead of devoting good ground and special care to scores or hundreds of "all alikes," instead of a collection in which "variety is indeed charming."

C. T. Druery, V.M.H., F.L.S.

SUBSTITUTES FOR THE LARCH.

Owing to the partial decline of the larch in this country several likely trees have at various times been brought forward as substitutes, such as the Douglas fir, Corsican pine, Sitka spruce, giant arborvitæ and others. Many of these trees have been planted in masses in various parts of the country, chiefly in an experimental way, but after a fair trial not one has proved itself a worthy substitute for the larch, althought doubtless some of those whose claims have been set forth may reflect one or more of its valuable qualities, but this is the widest limit of comparison.

The fact is, the larch has no equal as a profitable coniferous timber tree in this country, and I make this statement after thirty years of note-taking and comparison of its merits with some others whose admitted valuable qualities place them well ahead in the rank of such as are suitable for economic planting. Some points in favour of the wood of the larch may be briefly pointed out, such as value in a young state; for, comparatively speaking, from the youngest stages of its growth it can be utilised for stakes, fencing of a temporary kind, and other purposes, and this cannot be said of any other conifer grown in our woods, at least the durability of the timber of no other tree would be sufficient to repay the cost of erecting or otherwise converting.

The trunk of the larch is neither knotty nor crooked, but usually straight, and destitute of branches for three-fourths of its height, for above all trees the larch is one that is least inclined to throw its vigour and substance into the formation of heavy side branches. Then, a greater quantity of useful larch timber can be grown to the acre than is the case with any other conifer I know, excepting, perhaps, in the case of the native Scotch Pine. The durability of the wood of the larch is about double that of any other coniferous timber that can be recommended for afforesting purposes, while its extreme lightness—a cubic foot only weighing 34lb. —still further enhances its value.

Some years ago the merits of the timber of the Douglas fir were exploited by the then forester at Scone Palace, in Scotland, but of late little has been heard of the timber, and the numerous experiments carried out at Penrhyn Castle, in Wales, not with immature timber either, have demonstrated that although a large quantity of wood can be grown to the acre, yet its value by no means compares with that of the larch. It is a more expensive tree both to purchase and handle, while it cannot be compared with the larch either for planting in exposed situations or general hardihood.

The Corsican pine, too, has hardly come up to expectation as a substitute for the larch. It grows very rapidly, is perfectly hardy, and almost immune from the attacks of game, but it is expensive, and hard to transplant. Neither has the timber, even of trees of from fifty to seventy years' growth, been found as durable as could be desired, and it is too heavy and resinous for general use. A number of experiments were made with the timber some twenty years ago, both for indoor and outdoor purposes, and the results were as first stated. It certainly grows quicker than either the larch or Scotch pine—in one instance exceeding these in height by six feet in twenty-three years. But this is a common occurrence all over the country, and though the tree is a valuable one from many points of view, yet, as a timber producer, it will never approach the larch.

Then the giant arborvitæ has found favour with planters on account of its hardihood, rapid growth and quality of timber produced, but experiments carried out in Wales hardly warrant us in saying that it is to be generally recommended for afforesting purposes. The Sitka spruce, too, has its admirers, from a commercial point of view, but we must wait for some time before pronouncing on its behaviour as a tree for filling the place at present occupied by the larch.

Speaking candidly, after a long experence of many trees for profitable planting in this country, I am inclined to hold the view that the Scotch pine comes next to the larch as a profitable coniferous tree. It is cheap, readily transplanted, perfectly hardy, and when of mature age produces a large quantity of fairly valuable timber. Admitted that the wood of immature trees is not very lasting, it does well for temporary fencing, and, as compared with that of any other coniferous tree, most nearly approaches that of the larch. The tree is little subject to disease, and covers a vast range of soils, thriving and producing probably its best quality of timber on that of a poor gravelly texture. It is very questionable, when everything is taken into account, whether any other coniferous tree that is cultivated in this country can so nearly approach the larch, from an economic point of view, as the Scotch pine.

There are other useful coniferous trees of old standing, such as the common spruce, that must not be passed by in the search after substitutes for the larch, while the silver fir has its value in a particular line. Neither, of course, for general utility can compare with the larch, but when placed side by side with later-introduced species they are well worthy of attention. It is certainly much to be regretted that the larch has become diseased of late years, but there are hopes that the worst stages have been passed, and, as the owner of some of the largest larch plantations said to me the other day, "the disease is not to be dreaded as it was twenty years ago."

A. D. Webster.

Choisya ternata.—This, popularly termed the Mexican Orange Flower, is in many places greatly appreciated as an outdoor shrub. It is, under such conditions, much hardier then may be supposed. This, however, is not its only claim to recognition, as, grown in pots, it will flower freely in the greenhouse or conservatory during the spring months. In these structures its fragrant flowers and neat green leafage are always admired.—W.

CHOICE SUCCULENTS.

The term succulent is applied to plants in a general way to all those which provide against a period of drought by the development of aqueous or water-storing tissue, which serves to carry them over a time of scarcity of moisture, which may vary from a few days or weeks in the smaller kinds to even several years in the case of some of the larger kinds, such as the giant species of echinocactus and cereus. The aqueous tissue may be developed in the roots, stems, or leaves, either singly or collectively. Speaking generally, the amount of the development of succulent tissue is a useful guide as to the amount of water required during their resting period.

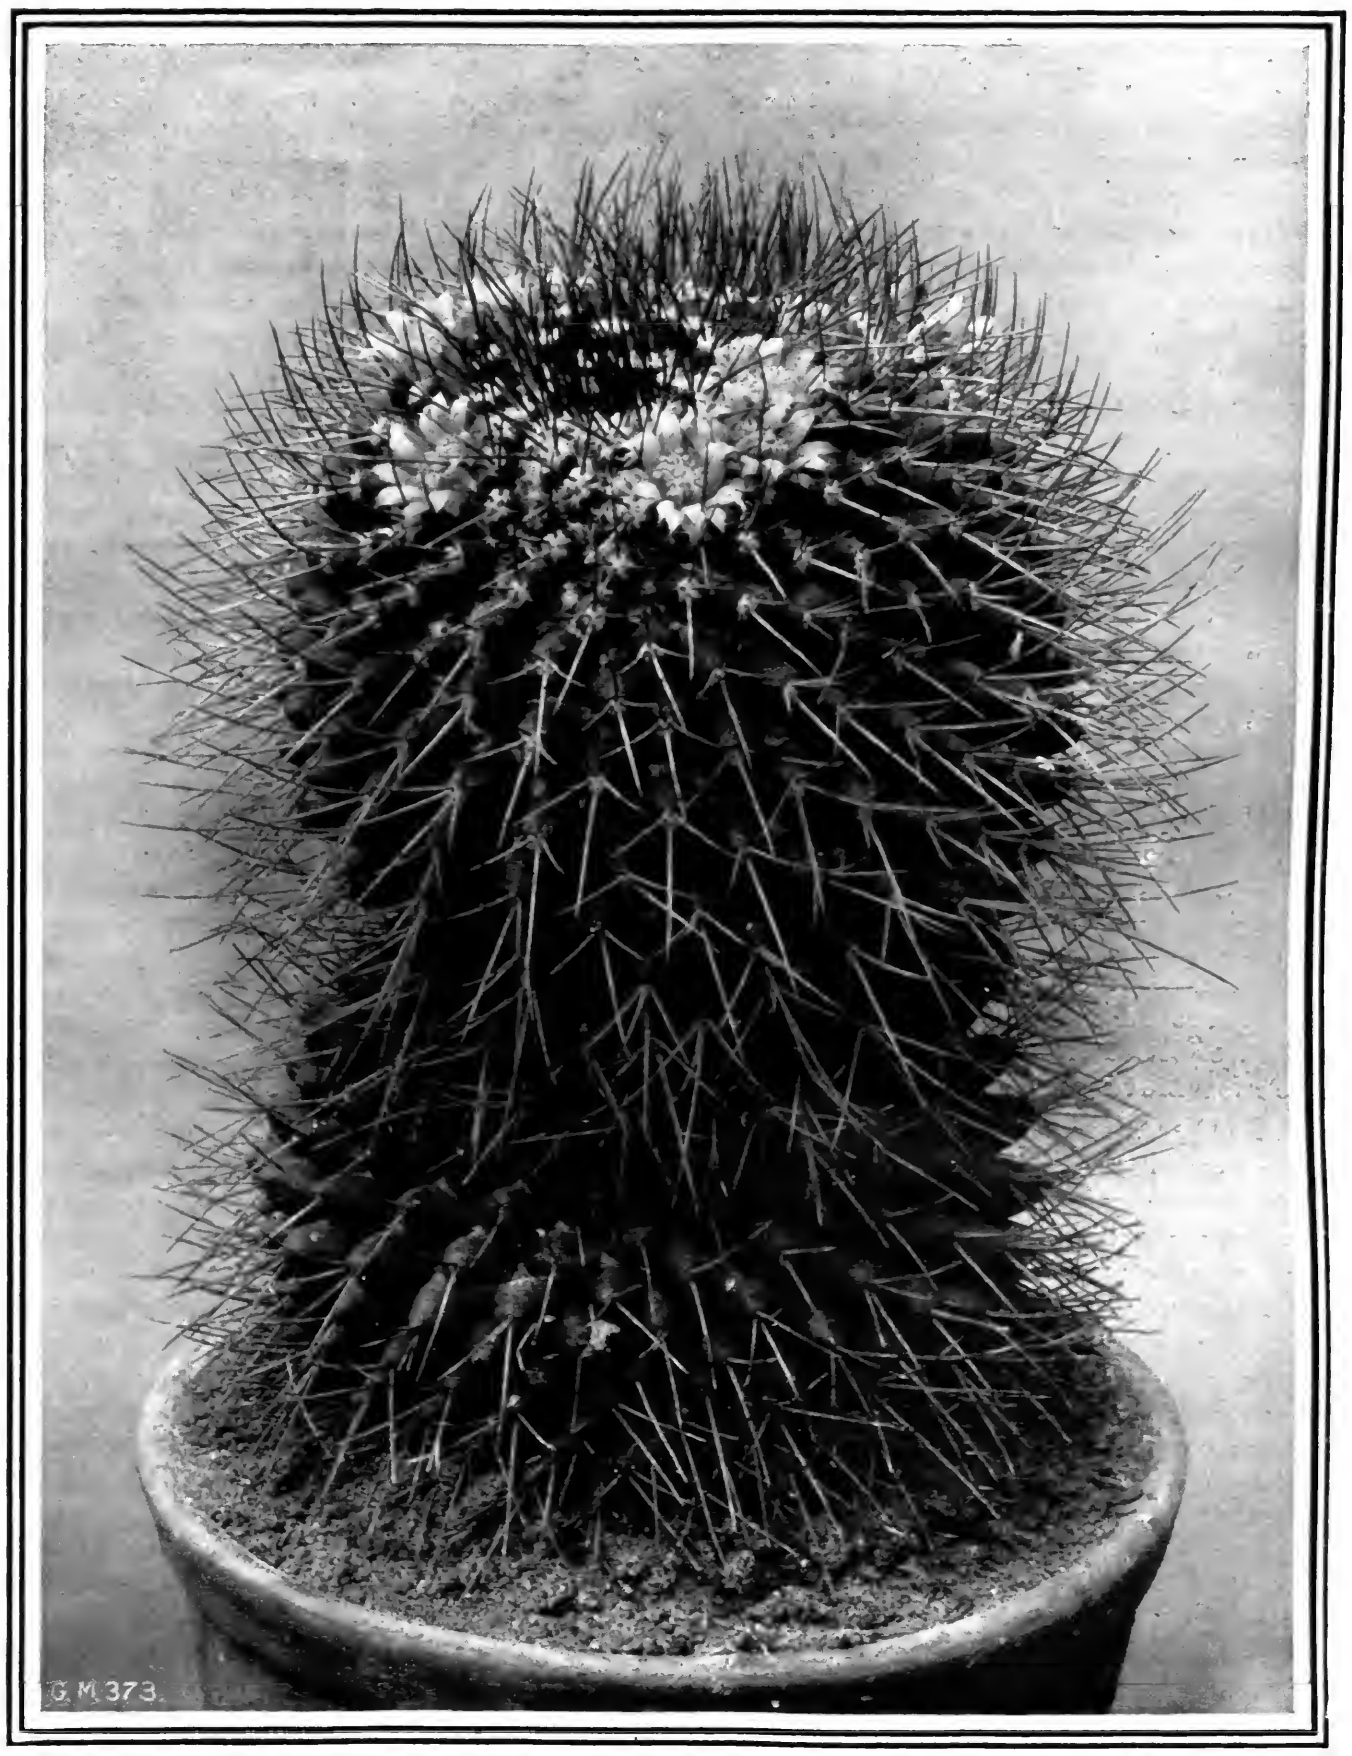
The greater the degree of succulence the longer the period of rest, and, inversely, the smaller the plant and the smaller the amount of water-storing tissue, the shorter the periods between each watering. Many of the shrubby kinds of mesembryanthemum, sempervivum, crassula, and rhipsalis, also such plants as stapelias, and most seedlings of the larger succulent plants in their early stages of development, must not be allowed to become thoroughly dry at the roots for many days at a time. It must be borne in mind in the treatment of succulent plants, as a whole, that one of the principal, if not the chief, points in their culture, is a healthy, buoyant atmosphere in the house in which they are grown. A stagnant state of the air, especially in winter-time, is the cause of many losses in collections of these plants. Such watering that is needed in the winter period should be done early in the morning, so that any excess of moisture may be eliminated during the rest of the day, either by ventilation or by giving additional heat. During the growing season (usually during the summer months) abundance of air should be given, both night and day; the water supply must also be proportionately increased. In fact, with many of these plants, the summer treatment is the same as for any ordinary greenhouse plant, both for watering, syringing, and ventilation. During favourable summers many succulent plants are considerably improved by being stood out in the open air. Practically all the agaves, cotyledons, yuccas, sedums, mesembryanthemums, and many opuntias are well suited for this treatment. It is not advisable in our changeable climate to risk many of the choicer kinds out of doors, as a spell of wet or cold weather may carry off some pet plant as the result. The damage may not be apparent for many months afterwards, and may not even be noticeable until the whole plant is a mass of decay. And this may only happen during the winter period, and be attributed to some other cause. With practically all succulents the growth which is made slowly and under fairly dry conditions is by far the best, and is better adapted to withstand the adverse conditions of our climate during the winter period, than the sappy, luxuriant growth which is made under moister conditions.

Any necessary repotting should be done from February to April. As a rule, most succulent plants thrive in a soil containing a fair amount of lime, Most of the cactaceæ contain a large amount of oxalate of lime, and this is best supplied to them in the form of crushed brick and mortar rubble mixed up in the potting compost. A suitable soil for the majority consists of the following ingredients: Two parts good turfy loam, one part of sand, and one of broken brick and mortar rubble. For stapelias the mortar is best left out, as they all grow on what is known as acid soils. Replace the mortar in this case with some granite siftings, and also add a little leaf-mould.

Propagation is a fairly easy matter with most succulents. The commonest method is by cuttings, and in the case of all the large, fleshy kinds, such as the cacti, euphorbias, aloes, and gasterias, they are best taken off and laid on a dry shelf for a week or so to allow the cut surface to dry and commence to callus. They may then be put into small pots in a very sandy mixture, and very carefully watered until rooted, when they should be potted up in the mixture, as previously advised for the majority of these plants. Cuttings of stapelias should not be inserted in the soil, but merely pegged down with a forked twig on the surface. The roots are emitted from the underside of the stem in contact with the soil. If inserted in the soil, as for ordinary cuttings, they are apt to damp off badly. The method advised is by far the best. Tall plants of almost any succulent which have become too large may be cut off at any length desired, and potted up again in the way advised for ordinary cuttings. This operation, if performed in early spring just previous to their normal period of growth, may be safely accomplished with many large plants. Such quick-growing plants as aloes and agaves appear to experience very little check in their development, and soon become established again.

Division is only of service in the dwarf tufted kinds of mammillaria, gasterias, Haworthia, a few of the echeverias, cotyledons, cereus, etc. Seeds, when obtainable, quickly germinate in a little heat and moisture. Seeds of most succulent plants retain their vitality for many years, and germinate in a few days. The reason of this is that they have to make the best of the rainy season when it does arrive, and obtain sufficient size and store up enough moisture in their tissues to carry them safely over the following period of drought. Any seed which delayed germination the moment the rains come stands but a poor chance in its struggle for existence.

Many species of agave, furcræa, stapelia, aloe, and mesembryanthemum are best increased from seeds; these grow rapidly, and soon make nice, serviceable plants. Most of the nurserymen dealing with these plants offer seeds of many kinds, and even the beginner will find very little difficulty in obtaining good results in the raising of seedlings. The point to bear in mind is not to allow them to become dry in their early stage of growth.



MAMMILLARIA CENTRICIRRHA.

The cactus family is a very extensive and variable class of plants, some of them reaching enormous proportions and weighing several tons; others are almost microscopic by way of comparison. With the exception of the Mistletoe Cactus (Rhipsalis cassytha) which is found in the African forests, all the genera and species are natives of the New World. The principal genera represented in gardens are cereus, mammillarias, echinocactus, opuntia, echinocereus, phyllocactus, and epiphyllum. The genus echinocactus is a very large and extensive one, containing hundreds of species and numerous varieties. They require somewhat warmer conditions than the majority of succulents, and very little water at any time of the year. They are usually of very slow growth, and often reach enormous proportions. They are densely clothed with stout and often brightly-coloured spines, arranged in clusters at intervals all over the rounded stems. The flowers are variable in colour, from white to yellow, orange, red, pink, or purple. They are comparatively small for the size of the plants, and are borne on the fasicles of spines near the top of the plant. A few of the best and most easily obtained are the following: E. Grusoni, with large, globose stems covered with bright yellow spines and bright red and yellow flowers. E. ornatus, with bright straw-coloured spines and deeply angular stems, of a rich green colour, and beautifully spotted and transversely barred with white. E. longitamatus, with rounded or slightly elongated stems, and long, hooked spines. E. Pfeifferi, similar to E. Grusoni, but longer and narrower in the stem. E. Williamsi, a small species of free-branching habit, and greenish flowers, tinted with rose. E. pilosa, a large, gouty-stemmed species with many angles, and covered with stout pink or rose-coloured spines. E. Wisleyeni, or Fish-hook Cactus. Plants of this species are obtainable from the tiny seedling stage to the giant adult specimens often half a ton in weight. The centre spine of each fasicle is much longer than the rest, strongly curved, and of great strength. These large spines are reputed to be used by the North American Indians as fish-hooks, hence the common name for this plant. The flowers are sulphur-yellow, and freely produced on large specimens. Many other most beautiful kinds could be included did space but permit.

The mammillarias are mostly dwarf, free-branching, or tufted cacti, the stems of which are covered with numerous outgrowths resembling mammæ, the apex of which bears a cluster of slender spines, varying in number in the different species, which number over 300. The members of this genus are amongst the most beautiful and symmetrical objects of the floral world. The flowers are rather small, but freely produced, and are usually some shade of yellow or rose, and a few are pure white. A few useful species for small collections are the following: M Grahami, Heyderi, eriacantha, macromeris, longimamma, micromeris, centricirrha, pusilla stellata, multiceps, lasiacantha, and Eichlami.

C. P. Raffill.

Begonia fuchsioides.—Tuberous-rooted begonias are so much grown that some members of the fibrous-rooted section are not met with as often as they well might be. This Mexican species, which is a quite old garden plant, is very beautiful when in good condition, the small, deep green leaves being disposed in a flattened frond-like manner on the shoots, and the deep scarlet flowers are borne in great profusion. It needs a warm greenhouse for its successful culture.—W.

THE USE OF ROSES.

"Roses everywhere" should be the practice, as well as the motto, of the ardent rose-lover, and, strange to say, gardeners who are ambitious of making every possible use of the Queen of flowers must begin by making summer purchases of pot specimens. Experiments have proved that the season of rose blooming, without artificial heat, can be wondrously extended, and with heated greenhouses the supply can be constant all the year round. To attain a simple success, the delight of a harvest of blossom during November and December, fine pot specimens of the best autumn-flowering roses should be bought in August, and entirely disbudded. Two methods should be adopted, as occasionally one produces better results than the other, and experiments have not yet been sufficiently numerous for proof to have been afforded of the style suited to special varieties.

Some of the new shoots that would naturally bloom in autumn should be removed, some only disbudded, and this should be done on the same plants in some cases, on separate plants in others, and a strict record be kept of the ultimate triumphs and failures. The pots may be kept in semi-sunshine in the open. Probably, positions between fruit trees, or where tall perennials, or rows or clumps of sweet peas, give occasional light shade, are best, as to range them against a fence or wall prevents healthy development on all sides of the bushes, and renders them more liable to disease and insect pests.

If the trees are fed with weak liquid manures in variety twice a week the grower will be well rewarded later on. Now disbudding can be variously performed, too; on some specimens it may be discontinued early, on others it has been continued until the beginning of October, but those were trees that could be housed by the middle of the month in an even temperature of 60 degrees. If the pot trees can only be placed in sunny, unheated greenhouses, the yield of bloom will be most satisfactory during November and early December. Gardeners who habitually force roses under glass will know that these are the months when there is a dearth of flowers, and experience is daily teaching the lesson that it is by the prolongation or retardation of the flowering of outdoor-grown roses in pots that the need is most easily met.

Window culture of roses deserves more consideration than it has yet received. Not only may the summer window-boxes, if made deeper than the ordinary, contain admirable rows of the dwarf Polyanthas, but these will flourish splendidly in pots inside rooms where ample ventilation is afforded. In short, the really wonderful displays that even cottage gardeners boast with such window plants as geraniums, primulas, fuchsias, and cacti, can be repeated solely with roses. The greenhouse favourites, Marechal Niel, Niphetos, etc., will flourish in tubs stood on the floor inside bay windows, as excellently as in glass porches or unheated conservatories. Even cold windows may be utilised for growing hardy roses in, Chinas and rugosas, during summer heat, the result being, with the first class, that the vigour of the trees is undiminished by late autumn, and if they are removed then to warm windows the blossom harvest will continue many weeks in perfection.

A garden all of roses is a glorious possibility, for there seems no use to which roses cannot be put. All that is needed is originality of conception and the pluck to run a few risks in experimenting. Hanging baskets of Wichuraiana roses, slung high on wires between poles that are themselves rose pillars, make a splendidly novel feature, especially appreciated in gardens visible from roadways; a long range of pillars on either side of a walk to a house entrance, with taut wire, or slightly slacked wire, between them, and on each wire such a basket, either of painted wire or rustic wood, creates an effect of dazzling beauty. Rockery banks may be sprawled over by the same class of rose, or afford perfect sheltered homes for the most delicate pegged-down teas, while hardier bushes can crown the summits. Grass banks may have a tree here and there in the turf sides, and shrubberies of wind-resisting varieties on the tops. A six feet bank, with a hedge of rugosas on the summit, is a screen equal in time, to a twelve feet wall.

A marvellously effective rockery mound in a front garden last year was simply planted at the top with one Gruss an Teplitz, the boughs of which had been bent over and pegged down here and there among the stones, forming miniature arches, from which lateral growths freely uprose.

A rose pavilion can be made for summer by planting the preceding autumn fine trees of the Dawson rose, against ten feet pillars, placed two yards apart, in a semi-circle. So prodigious is the growth of this species of weeping habit that the branches will prove sufficient to stretch across to form a roof, supported then by a twelve or fourteen feet pillar in the centre of the pavilion. To secure autumn florescence a climbing hybrid tea rose may be grown on four pillars between the original ones, if desired.

Roses for edging beds may be employed. The peach-blush Ma Filette, or the dwarf Scotch rose, answer the purpose admirably, as would other low-growing species, or varieties, that flower freely when clipped. Of the beauty of rose hedges, roses by the water, rose glades, and arbours, no mention need specially be made. Roof tops may be overhung by trailing Wichuraianas, urns, vases, and raised beds of roses are singularly effective. Lastly, a glass pavilion as a lawn centrepiece, devoted solely to the culture of roses inside and out, can be recommended as a picturesque novelty that should be summer-prepared for winter filling.

M. H.

The Seed Industry of the United Kingdom.—The interesting article on the above subject, and the numerous illustrations that accompanied it in the Gardeners' Magazine, serve to show the great pains that are taken to clean and test the germinating power of seeds before they are sent out. Visits to trial grounds during the season will serve to further emphasise the care taken, for beds of seedlings may be seen in which it is quite the exception to find a single rogue. I never spent a more enjoyable afternoon than one last summer at Messrs. J. Carter and Co.'s trial grounds at Raynes Park. The general invitation is to come and see, and my experience is that not only is there a great deal to see, but every facility is given for the visitor to inspect all objects of interest. The grounds being given up to trial purposes, one does not meet with hugh stretches or fields of one particular kind, but rather with beds of a variety planted in order to show whether there is any tendency to break away from the type. In the case of most of their own stocks the regularity of the plants was remarkable, but with those that had been submitted to them and were therefore strictly under trial, the same, in some cases at least, could not be said. This shows the necessity of a rigid supervision such as that carried out by the leading firms, and by means of which the correctness of stocks is fully ensured.—S. W.

CULTIVATION OF ASPARAGUS.

Raising Young Plants.

Large growers of asparagus usually sow seed from their own plants, and so there is no question of new seed or new varieties. Cultivation is, in the opinion of experts, a much more important factor in determining the value of the crop than the variety grown. However, it may be said that the chief kinds are Connover's Colossal, Argenteuil (Early Giant and Early Giant French), and Palmetto. Perhaps the best method of raising a stock is to use one-year-old seedlings, raised at home, making preparations for seed sowing as early as possible, and committing the seed to the ground in March. Purchased two or three-year-old plants are sometimes used in order to save time, but this plan would not do for market culture, as they do not travel well, and the slightest injury to them usually means disaster in the end.

Formerly asparagus was grown in narrow beds containing two rows of plants, but the modern method consists of a single row culture, allowing as much space as possible for the plants to develop. In France, where size is the chief consideration, a space of 4ft. is allowed between the rows. The March sowings should be made in a carefully-prepared seed bed in drills nine inches apart, and when the seedlings are a year old they are lifted and planted in rows from three to three and a-half feet apart, and one foot apart in the rows. It is well not to overcrowd the plants in any way, for this can only end in their starvation.

Formation of Beds.

Manuring and the preparation of the soil is, of course, extremely important to the success of the culture, but a very great deal also depends on the selection of the plants, which, it may be remarked, retain their own characteristics during their whole existence. In other words, it is important to select the strongest one-year-old plants, which appear to bear a small number of strong shoots, and have all their roots intact. Then the soil on which they are planted must of necessity be fairly moist, but not by any chance waterlogged. A deep, sandy loam seems to be best suited to asparagus culture, but damp shallow soils are naturally unsuited to the crop unless they are thoroughly drained and deepened by judicious cultivation. In the Vale of Evesham it is customary to dig the ground very thoroughly in the autumn, meanwhile breaking up the subsoil below, and incorporating with it a generous admixture of well-rotted manure. Natural manures of a somewhat cold and heavy nature, such as cow dung, or a mixture of cow dung and horse manure, are well suited for poor, sandy soils that are lacking in humus, while the debris from mushroom beds also fulfils a very useful purpose in this direction.

After Cultivation.

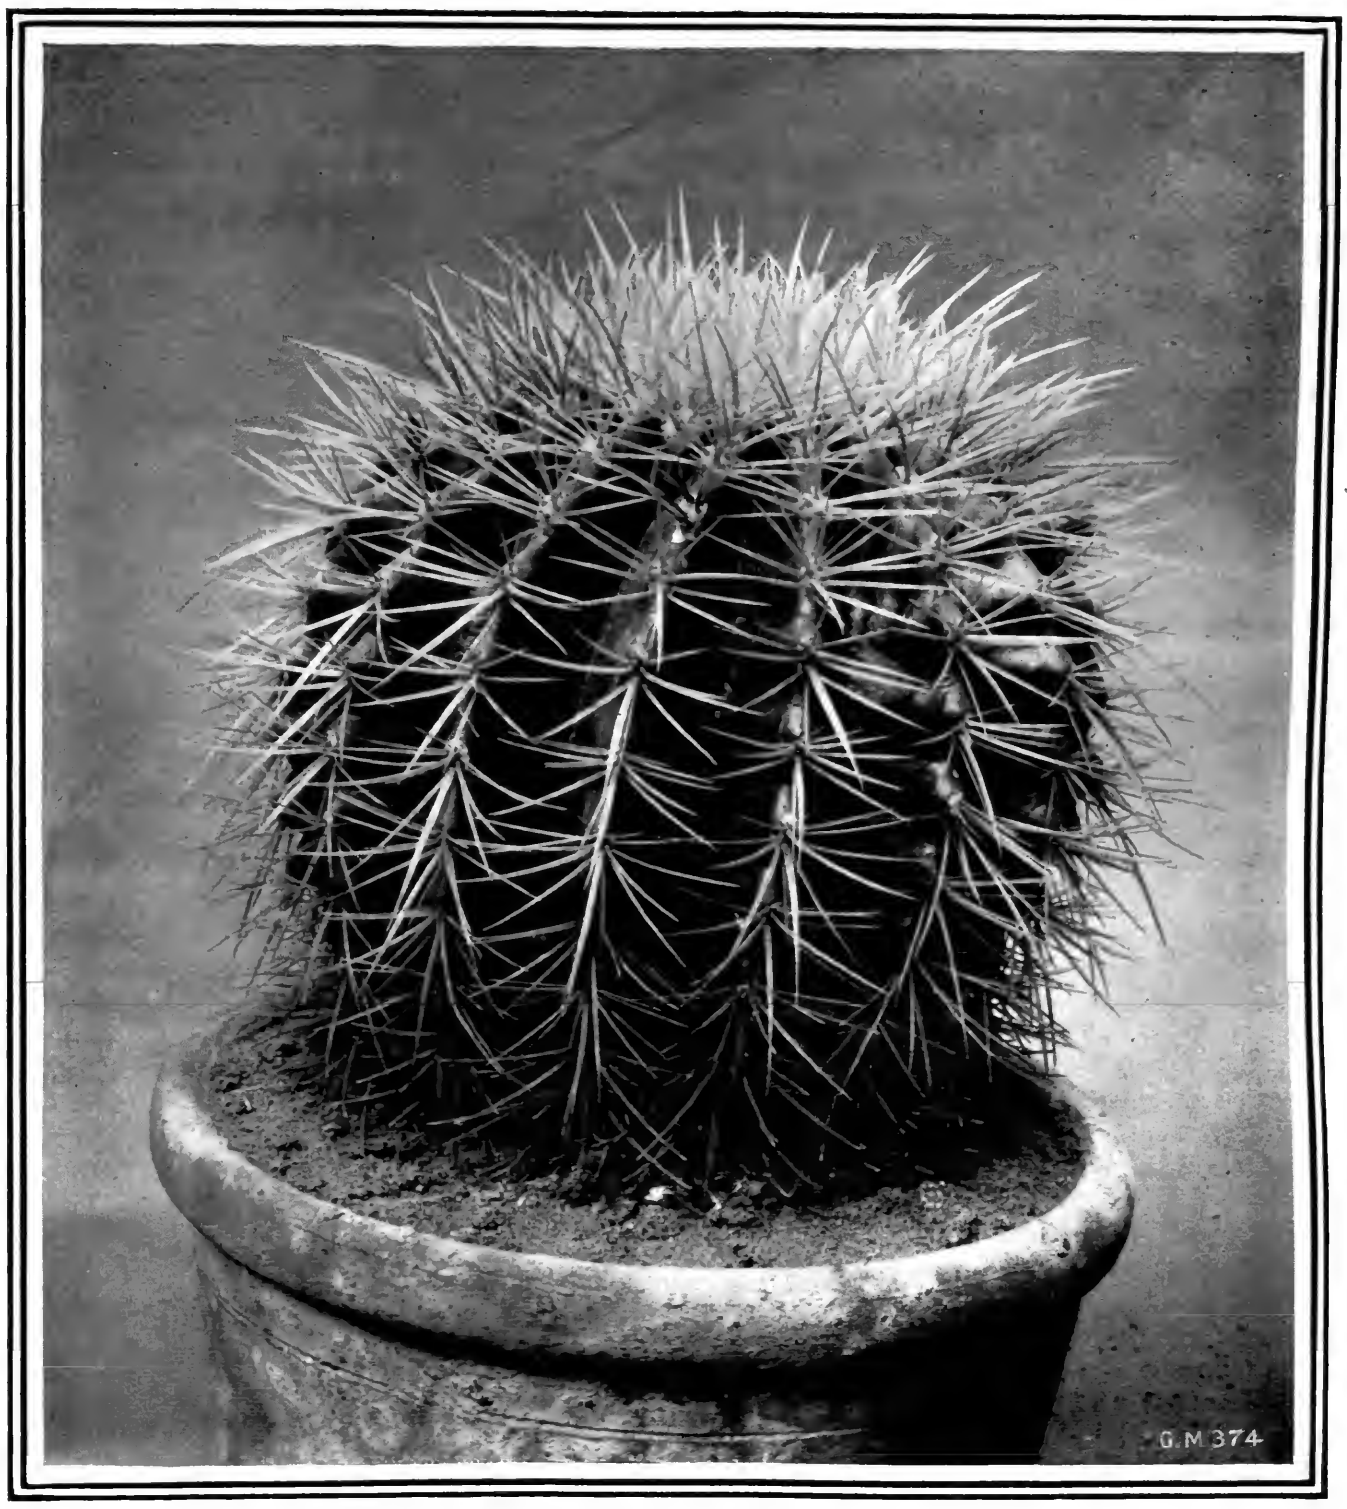
Asparagus, it may be remarked, requires an abundance of moisture, especially in summer, and, if the soil appears to be too light and porous, an attempt must be made to increase its retentiveness by adding a suitable quantity of manure. Usually, when the soil is dug and manured in the autumn, soot is added at the rate of one ton per acre, and this dressing is subsequently repeated every alternate year.

The after cultivation of asparagus consists chiefly in manuring, hoeing between the rows, earthing up, and cutting. For the first year the hoe should be used assiduously between the rows in order to keep down weeds, and care should be taken to prevent any ravage by the asparagus beetle. In November, the stems are cut down and the ridges levelled, while in the second autumn a slight ridge is formed about the plants by drawing a little soil up with the hoe, leaving the stalks so protected until the following spring.

There is, first of all, however, the question of manuring the crop before and after cutting to be considered. Of course, no feeding will be required for the first year after planting, but in the case of established beds it will be advisable to give a liberal dressing of farmyard manure every year in June or July, after cutting. On light soils this annual dressing of farmyard manure is extremely beneficial, because it helps to keep the land retentive of moisture, besides putting it in better heart for a succeeding crop. Nitrate of soda, applied as a top-dressing at the rate of from two and a-half to three cwts. per acre, is also a valuable stimulant to the asparagus plant in spring. It should be given at intervals of two weeks in three dressings, commencing with the springing of the heads. Sometimes guano or sulphate of ammonia is used instead of nitrate of soda, and fish meal and dried blood are also utilised for a similar purpose by some growers.

On poor or light sandy soils salt is used very extensively as a fertiliser for asparagus, but kainit would be better. Spring applications of salt are usually made at the rate of two pounds to the square yard before the new shoots commence to break; it not only assists the asparagus, but also destroys weeds of all descriptions, and at the same time serves as a valuable insecticide where the asparagus beetle is troublesome. As a good liquid stimulant for asparagus, to be applied in summer, there is nothing better than a mixture of one pound of salt, one pound of guano, and twenty gallons of water.

Old Basing. J. C. Newsham.



ECHINOCACTUS GRUSONI.

A Valuable Handbook, designed to supply sound, practical information on the profitable cultivation of Asparagus, is published from the office of this journal. Included within the volume will also be found details as to the growing of Beans, Cardoons, Celery, Artichokes, Seakale, Peas, etc. It contains the knowledge needful to cultivate crops successfully, and may be procured from the Publisher, 148, Aldersgate Street, London, for 1s. 2d., post free.

PERPETUAL CARNATIONS.

The spell of rather dull, rainy weather experienced some weeks since has been inimical to perpetual carnations, and blossoms have not been either so good in quality or in numbers as would have been the case if the weather had been brighter and drier. The conditions which have militated against our carnations on this side of the Atlantic have also exercised the same effect upon the stocks of the American growers, and many complaints are heard concerning the short crop of blossom obtained of late. A spell of bright weather will speedily put a better aspect upon things, but one is impelled to note varieties which give the best results during these days of cloud, fog, and rain.

My heaviest cut of blossoms since Christmas has been from Pink Elegance, but probably this will not get into general cultivation by reason of the blossoms lacking a little in size, but at this season it is always my brightest and freest variety. It is just what that old American raiser, F. Dorner, would have called an "ever-blooming, bread and butter carnation." It has colour, a splendid stem, and, unlike so many carnations, it goes straight for blossom. Our next largest crop was obtained from Indian Robe, smaller and brighter than Afterglow. This is of bushy habit, stiff wiry stems, and gives a warm touch of Indian red, which, like the old Mrs. Theodore Roosevelt lights up splendidly under artificial light. It is a question whether we shall retain Indian Robe after another season or two, as we have seedlings of the same shade which throw larger blossoms. Mrs. C. W. Ward and May Day are both valuable at this time, and the pretty pink and white Alma Ward may also be noted.

In scarlets the best has been Andrew Carnegie, which is valuable for winter use, while Harlowarden seems still the freest crimson, though a little on the small side. Speaking of scarlets, the old discussion of the best will soon doubtless again be raised. The merits of Beacon, Bonfire, Scarlet Glow, and the newer St. Nicholas will be surveyed. Soon we shall have the new American scarlet, The Herald, to swell the list. This is doubtless a splendid thing as grown in the States, and it scored 87 points out of a possible 100 at St. Louis, and 89 points at the Chicago Florists' Club last year. In addition to this, it was first for 100 blooms of a scarlet variety at Cincinnati in 1911, and first at St. Paul and Cleveland in 1912. Its colour is clear, the flowers well formed, stem and calyx very good. Commodore, another new scarlet, has a good character for the quantities of blooms produced in the winter, and should be given a trial on this account alone.

Another scarlet which is being put on the market in the States is Comfort, a variety which promises well, and is being propagated in large quantities. Two new red carnations are Red Springs, a variety recently certificated in Nassau County, and William Eccles, which was well shown on January 13 by Scott Brothers at the New York Florists' Club.

Another notable feature of carnation culture in America is the commanding position taken by the new forms of Enchantress. Of these Enchantress Supreme, a fine salmon-pink sport, a very attractive shade, calls for attention. It is identical in growth with its popular parent, but is reputed to hold its colour better. It has a longer calyx, and is non-bursting. Another sport, Salmon Beauty, is going ahead rapidly. This has rather more of the salmon hue, and may be regarded as a really good all-round variety.

A New York grower has a variety very near to Enchantress under the name of Improved Enchantress, but whether this is a good selected sport, or a natural seedling, I am unable to say. The fine dark pink Northport received a Certificate of Merit on January 13, with the report of 86½ points in its favour. This is undoubtedly a coming carnation, and will quickly find its way into English gardens.

The new white, Matchless, is very favourably regarded, and gained 89 points under comparative tests, being pure and free.

It would be interesting, too, to know just how a member of the Fairfield Society (America) obtained what was shown as the yellow sport of Mrs. C. W. Ward. It seems hardly feasible that this favourite carnation should give a clear yellow sport, and I, for one, would like to know a little more of the history of this new variety. One thing is certain, that if it will produce good yellow blossoms of the size and form of Mrs. Ward, it is assured of a good reception.

The new pink carnation Philadelphia, is attracting much attention among American growers. It was raised, and has been grown for four years, by Mr. T. Browne, of Greenfield, Michigan, but its merits have attracted other growers, a few of whom recently combined and secured the whole stock for a large sum. It is of a soft, shining shade of pink, quite distinct from any variety in commerce. It is strong in growth, continuous, and the calyx is very good, and has been favourably commented upon by many leading growers. The owners intend to wait another year before placing it in commerce, by which time the stock will have reached a very large number.

P. S. Hayward.

CINERARIAS.
